
ENCYCLOPÆDIA BRITANNICA.

VOLUME the SECOND.

ENCYCLOPÆDIA Britannica:

OR, A

DICTIONARY

OF

ARTS and SCIENCES,

COMPILED UPON A NEW PLAN.

IN WHICH

The different SCIENCES and ARTS are digeſted into diſtinct Treatiſes or Syſtems;

AND

The various TECHNICAL TERMS, &c. are explained as they occur in the order of the Alphabet.

ILLUSTRATED WITH ONE HUNDRED AND SIXTY COPPERPLATES.

By a SOCIETY *of* GENTLEMEN *in* SCOTLAND.

IN THREE VOLUMES.

VOL. II.

Encyclopædia Britannica;

OR, A NEW

DICTIONARY

OF

ARTS and SCIENCES.

CAABA, or CAABAH, properly ſignifies a ſquare building; but is particularly applied by the Mahometans to the temple of Mecca, built, as they pretend, by Abraham and Iſmaël his ſon. It is towards this temple they always turn their faces when they pray, in whatever part of the world they happen to be.

This temple enjoys the privilege of an aſylum for all ſorts of criminals; but it is moſt remarkable for the pilgrimages made to it by the devout muſſulmans, who pay ſo great a veneration to it, that they believe a ſingle ſight of its ſacred walls, without any particular act of devotion, is as meritorious, in the ſight of God, as the moſt careful diſcharge of one's duty, for the ſpace of a whole year, in any other temple.

CAB, an Hebrew dry meaſure, being the ſixth part of a ſeah or ſatum, and the eighteenth part of an ephah: A cab contained $2\frac{5}{6}$ pints of our corn meaſure: A quarter-cab was the meaſure of dove's dung, or more properly a ſort of chick-peaſe, called by this name, which was ſold at Samaria, during the ſiege of that city, for five ſhekels.

CABALIST, in French commerce, a factor, or perſon, who is concerned in managing the trade of another.

CABALLARIA, in middle-age writers, lands held by the tenure of furniſhing a horſeman, with ſuitable equipage, in time of war, or when the lord had occaſion for him.

CABALLEROS, or CAVALLEROS, are Spaniſh wools, of which there is a pretty conſiderable trada at Bayonne, in France.

CABALLINE denotes ſomething belonging to horſes: Thus caballine aloes is ſo called, from its being chiefly uſed for purging horſes; and common brimſtone is called ſulphur caballinum, for a like reaſon.

CABBAGE, in botany. See BRASSICA.

CABBAGE-*tree*, a name ſometimes given to the palm-tree, called by Linnæus, phœnix. See PHOENIX.

CABBAGING, among gardeners, a term uſed for the knitting of cabbages into round heads.

CABBALA, according to the Hebrew ſtyle, has a very diſtinct ſignification from that wherein we underſtand it in our language. The Hebrew cabbala ſignifies tradition; and the rabbins, who are called cabbaliſts, ſtudy principally the combination of particular words, letters, and numbers, and by this means pretend to diſcover what is to come, and to ſee clearly into the ſenſe of many difficult paſſages in ſcripture: There are no ſure principles of this knowledge, but it depends upon ſome particular traditions of the ancients; for which reaſon it is termed cabbala.

The cabbaliſts have abundance of names, which they call ſacred: Theſe they make uſe of in invoking of ſpirits, and imagine that they receive great light from them: They tell us, that the ſecrets of the cabbala were diſcovered to Moſes on mount Sinai; and that theſe have been delivered down to them from father to ſon, without interruption, and without any uſe of letters; for to write them down, is what they are by no means permitted to do. This is likewiſe termed the oral law, becauſe it paſſed from father to ſon, in order to diſtinguiſh it from the written laws.

There is another cabbala, called artificial, which conſiſts in ſearching for abſtruſe and myſterious ſignifications of a word in ſcripture, from whence they borrow certain explanations, by combining the letters which

which compoſe it: this cabbala is divided into three kinds, the gematrie, the notaricon, and the temura or themurah. The firſt whereof conſiſts in taking the letters of a Hebrew word for ciphers or arithmetical numbers, and explaining every word by the arithmetical value of the letters whereof it is compoſed. The ſecond ſort of cabbala, called notaricon, conſiſts in taking every particular letter of a word for an entire diction; and the third, called themurah, *i. e.* change, conſiſts in making different tranſpoſitions or changes of letters, placing one for the other, or one before the other.

Among the Chriſtians likewiſe, a certain ſort of magic is, by miſtake, called cabbala, which conſiſts in uſing improperly certain paſſages of ſcripture for magic operations, or in forming magic characters or figures with ſtars and taliſmans.

Some viſionaries, among the Jews, believe, that Jeſus Chriſt wrought his miracles by virtue of the myſteries of the cabbala.

CABBALISTS, the Jewiſh doctors who profeſs the ſtudy of the cabbala.

In the opinion of theſe men, there is not a word, letter, or accent in the law, without ſome myſtery in it. The Jews are divided into two general ſects; the karaites, who refuſe to receive either tradition or the talmud, or any thing but the pure text of ſcripture; and the rabbiniſts, or talmudiſts, who, beſides this, receive the traditions of the ancients, and follow the talmud.

The latter are again divided into two other ſects; pure rabbiniſts, who explain the ſcripture, in its natural ſenſe, by grammar, hiſtory, and tradition; and cabbaliſts, who, to diſcover hidden myſtical ſenſes, which they ſuppoſe God to have couched therein, make uſe of the cabbala, and the myſtical methods above mentioned.

CABECA, or CABESSE, a name given to the fineſt ſilks in the Eaſt Indies, as thoſe from 15 to 20 *per cent.* inferior to them are called barina. The Indian workmen endeavour to paſs them off one with the other; for which reaſon, the more experienced European merchants take care to open the bales, and to examine all the ſkains one after another. The Dutch diſtinguiſh two ſorts of cabecas; namely, the moor cabeca, and the common cabeca. The former is ſold at Amſterdam for about 21½ ſchellinghen Flemiſh, and the other for about 18½.

CABENDA, a port-town of Congo, in Africa, and ſubject to the Portugueſe: E. long. 12°, and S. lat. 4°.

CABIDOS, or CAVIDOS, a long meaſure uſed at Goa, and in other places of the Eaſt Indies belonging to the Portugueſe, to meaſure ſtuffs, linens, &c. and equal to 4/7 of the Paris ell.

CABIN, in the ſea-language, a ſmall room, or apartment, whereof there are a great many in ſeveral parts of a ſhip; particularly on the quarter-deck, and on each ſide of the ſteerage, for the officers of the ſhip to lie in.

The great cabin is the chief of all, and that which properly belongs to the captain or chief commander.

CABINET, or CABBINET, the moſt retired place in the fineſt part of a building, ſet apart for writing, ſtudying, or preſerving any thing that is precious.

A complete apartment conſiſts of a hall, anti-chamber, chamber, and cabinet, with a gallery on one ſide. Hence we ſay, a cabinet of paintings, curioſities, &c.

CABINET alſo denotes a piece of joiner's workmanſhip, being a kind of preſs or cheſt, with ſeveral doors and drawers.

There are common cabinets of oak or of cheſnut, varniſhed cabinets of China and Japan, cabinets of inlaid work, and ſome of ebony, or the like ſcarce and precious woods.

Formerly the Dutch and German cabinets were much eſteemed in France, but are now quite out of date, as well as the cabinets of ebony, which came from Venice.

CABIRI, a term in the theology of the ancient Pagans, ſignifying great and powerful gods; being a name given to the gods of Samothracia. They were alſo worſhipped in other parts of Greece, as Lemnos and Thebes, where the cabiria were celebrated in honour of them: theſe gods are ſaid to be, in number, four, *viz.* Axieros, Axiocerſa, Axiocerſus, and Caſmilus.

CABIRIA, feſtivals in honour of the cabiri, celebrated in Thebes and Lemnos, but eſpecially in Samothracia, an iſland conſecrated to the cabiri. All who were initiated into the myſteries of theſe gods, were thought to be ſecured thereby from ſtorms at ſea, and all other dangers. The ceremony of initiation was performed by placing the candidate, crowned with olive-branches, and girded about the loins with a purple ribband, on a kind of throne, about which the prieſts, and perſons before initiated, danced.

CABLAN, the name of a kingdom and city of India, beyond the Ganges.

CABLE, a thick, large, ſtrong rope, commonly of hemp, which ſerves to keep a ſhip at anchor.

There is no merchant-ſhip, however weak, but has at leaſt three cables; namely, the chief cable, or cable of the ſheet-anchor, a common cable, and a ſmaller one.

Cable is alſo ſaid of ropes, which ſerve to raiſe heavy loads, by the help of cranes, pullies, and other engines. The name of cable is uſually given to ſuch as have, at leaſt, three inches in diameter; thoſe that are leſs are only called ropes of different names, according to their uſe.

Every cable, of what thickneſs ſoever it be, is compoſed of three ſtrands; every ſtrand of three ropes; and every rope of three twiſts: the twiſt is made of more or leſs threads, according as the cable is to be thicker or thinner.

In the manufacture of cables, after the ropes are made, they uſe ſticks, which they paſs firſt between the ropes of which they make the ſtrands, and afterwards between the ſtrands of which they make the cable, to the end that they may all twiſt the better, and be more regularly wound together; and alſo, to prevent them from twining or intangling, they hang, at

at the end of each ſtrand and of each rope, a weight of lead or of ſtone.

The number of threads each cable is compoſed of is always proportioned to its length and thickneſs; and it is by this number of threads that its weight and value are aſcertained: thus a cable of three inches circumference, or one inch diameter, ought to conſiſt of 48 ordinary threads, and weigh 192 pounds; and on this foundation is calculated the following table, very uſeful for all people engaged in marine commerce, who fit out merchant-men for their own account, or freight them for the account of others.

A table of the number of threads and weight of cables of different circumferences.

Circumf.	Threads.	Weight.
3 inches.	48	192 pounds
4	77	308
5	121	484
6	174	696
7	238	952
8	311	1244
9	393	1572
10	485	1940
11	598	2392
12	699	2796
13	821	3284
14	952	3808
15	1093	4372
16	1244	4976
17	1404	5616
18	1574	6296
19	1754	7016
20	1943	7772

Sheet-anchor CABLE, is the greateſt cable belonging to a ſhip.

Serve or plate the CABLE, is to bind it about with ropes, clouts, *&c.* to keep it from galling in the hawſe.

To ſplice a CABLE, is to make two pieces faſt together, by working the ſeveral threads of the rope, the one into the other.

Pay more CABLE, is to let more out of the ſhip. *Pay cheap the cable,* is to hand it out apace. *Veer more cable,* is to let more out, *&c.*

CABLED, in heraldry, a term applied to a croſs, formed of the two ends of a ſhip's cable; ſometimes alſo to a croſs covered over with rounds of rope, more properly called a croſs-corded.

CABLED-*flute,* in architecture, ſuch flutes as are filled up with pieces, in the form of a cable.

CABO DE ISTRIA, the capital of the province of Iſtria, in the dominion of Venice, ſituated on the gulph of Venice, about twelve miles ſouth of Trieſte: E. long. 14° 20′, and N. lat. 45° 50′.

CABOCHED, in heraldry, is when the heads of beaſts are borne without any part of the neck, full-faced.

CABOLETTO, in commerce, a coin of the republic of Genoa, worth about 3 d. of our money.

CABUL, the capital of a province of the ſame name, on the north-weſt of India. Both the town and province of Cabul were ceded to the Perſians in 1739: E. long. 69°, and N. lat. 33° 30′.

CABURNS, on ſhip-board, are ſmall lines, made of ſpun yarn, to bind cables, ſeize tackles, or the like.

CACACA, a city of Africa, in the kingdom of Fez.

CACAGOGA, among ancient phyſicians, ointments, which, applied to the fundament, procure ſtools. Paulus Ægineta directs to boil alum, mixed with honey, for that purpoſe.

CACALIA, in botany, a genus of the ſyngeneſia polygamia æqualis claſs. The receptacle is naked; the pappus is hairy; and the calix is cylindrical, oblong, and has a kind of ſmall cup at the baſe. There are 12 ſpecies, none of which are natives of Britain.

CACALIANTHEMUM, in botany, a ſynonime of the cacalia. See CACALIA.

CACAO, in botany. See THEOBROMA.

CACERES, a town of Eſtremadura, in Spain, about ſeventeen miles ſouth-eaſt of Alcantara: W. long. 6° 45′, and N. lat. 39° 12′.

CACHAN, a city of Perſia, ſituated in a large plain, about 20 leagues from Iſpahan.

It is remarkable for its manufactures of gold and ſilver ſtuffs, and of fine earthen ware.

CACHAO, or KECHIO, the capital of the kingdom of Tonquin, ſituated on the weſtern ſhore of the river Domea: E. long. 105°, and N. lat. 22° 30′.

CACHECTIC, ſomething partaking of the nature of, or belonging to a cachexy. See CACHEXY.

CACHEMIRE, or KACHEMIRE, a province of Aſia, in the country of the Mogul. The inhabitants are thought to have been originally Jews, becauſe they ſpeak much of Moſes and Solomon, whom they believe to have travelled into their country.

CACHEMIRE is alſo the capital of that province, ſituated in 76° E. long. and 34° 30′ N. lat.

CACHEXY, in medicine, a vitious ſtate of the humours and whole habit. See MEDICINE.

CACHRYS, in botany, a genus of the pentandria digynia claſs. The fruit is oval and a little angled. There are but two ſpecies, *viz.* the libanotis, a native of Sicily; and the ſicula, a native of Sicily and Spain.

CACOETHES, in medicine, an epithet applied, by Hippocrates, to malignant and difficult diſtempers: when applied to ſigns or ſymptoms, it imports what is very bad and threatening; and if given to tumours, ulcers, *&c.* it denotes a great malignancy.

CACTUS, in botany, a genus of the icoſandria monogynia claſs. The calix conſiſts of one leaf, imbricated, and above the fruit. The berry has but one cell, containing many ſeeds. The ſpecies are twenty-three, one of which is the cochineal-plant. See COCHINEAL.

CAD, or CADE. See CADE.

CADARI, or KADARI, a ſect of Mahometans, which attributes the actions of men to men alone, and not to the divine decree determining his will; and denies all abſolute decrees, and predeſtination. Ben Aun calls the cadari, the magi or manichees of the muſſulmans.

CADE, a cag, caſk, or barrel. A cade of herrings is a veſſel containing the quantity of 500 red herrings, or of ſprats 1000.

CADE-LAMB, a young lamb, weaned and brought up by hand in a houſe.

CADE-OIL, an oil much uſed in France and Germany: it is prepared from the fruit of a ſpecies of cedar, called *oxycedrus*.

CADE-WORM, in zoology, the maggot or worm of a fly, called phryganea. See PHRYGANEA.

CADENCE, in reading, is a falling of the voice below the key note at the cloſe of every period. In reading, whether proſe or verſe, a certain tone is aſſumed which is called the key-note; and in this tone the bulk of the words are ſounded; but this note is generally lowered towards the cloſe of every ſentence.

CADENCE, in muſic, according to the ancients, is a ſeries of a certain number of notes, in a certain interval, which ſtrike the ear agreeably, and eſpecially at the end of the ſong, ſtanza, *&c.* It conſiſts ordinarily of three notes.

Cadence, in the modern muſic, may be defined a certain concluſion of a ſong, or of the parts of a ſong, which divide it, as it were, into ſo many numbers or periods. It is when the parts terminate in a chord or note, the ear ſeeming naturally to expect it; and is much the ſame in a ſong, as the period that cloſes the ſenſe in a paragraph of a diſcourſe.

A cadence is either perfect, conſiſting of two notes ſung after each other, or by degrees conjoined in each of the two parts, and by theſe means ſatisfying the ear; or imperfect, when its laſt meaſure is not in the octave or uniſon, but a ſixth or third. It is called imperfect, becauſe the ear doth not acquieſce in the concluſion, but expects a continuation of the ſong. The cadence is ſaid to be broken, when the baſs, inſtead of falling a fifth, as the ear expects, riſes a ſecond, either major or minor. Every cadence is in two meaſures; ſometimes it is ſuſpended, in which caſe it is called a repoſe, and only conſiſts of one meaſure, as when the two parts ſtop at the fifth, without finiſhing the cadence. With regard to the baſs-viol, Mr Rouſſeau diſtinguiſhes two cadences, one with a reſt, when the finger, that ſhould ſhake the cadence, ſtops a little, before it ſhakes, on the note immediately above that which requires the cadence; and one without a reſt, when the ſtop is omitted.

CADENCE, in the menage, an equal meaſure or proportion, obſerved by a horſe in all his motions; ſo that his times have an equal regard to one another, the one does not embrace or take in more ground than the other, and the horſe obſerves his ground regularly.

CADENE, one of the ſorts of carpets which the Europeans import from the Levant. They are the worſt ſort of all, and are ſold by the piece from one to two piaſters per carpet.

CADET, the younger ſon of a family, is a term naturalized in our language from the French. At Paris, among the citizens, the cadets have an equal patrimony with the reſt. At Caux, in Normandy, the cuſtom, as with us, is to leave all to the eldeſt, except a ſmall portion to the cadets. In Spain, it is uſual for one of the cadets in great families to take the mother's name.

CADET is alſo a military term denoting a young gentleman who chuſes to carry arms in a marching regiment as a private man. His views are, to acquire ſome knowledge in the art of war, and to obtain a commiſſion in the army. Cadet differs from volunteer, as the former takes pay, whereas the latter ſerves without any pay.

CADI, or CADHI, a judge of the civil affairs in the Turkiſh empire.

It is generally taken for the judge of a town; judges of provinces being diſtinguiſhed by the appellation of molla's.

In Biledulgerid in Africa, the cadi decides in ſpiritual affairs.

CADILESCHER, a capital officer of juſtice among the Turks, anſwering to a chief juſtice among us.

It is ſaid, that this authority was originally confined to the ſoldiery; but that, at preſent, it extends itſelf to the determination of all kinds of law-ſuits; yet nevertheleſs ſubject to appeals.

There are but three cadileſchers in all the grand ſignior's territories; the firſt is that of Europe; the ſecond, of Natolia; and the third reſides at Grand Cairo. This laſt is the moſt conſiderable: they have their ſeats in the divan next to the grand vizir.

CADIZ, a city and port-town of Andaluſia in Spain, ſituated on the north-weſt end of the iſland of Leon, or Lyon, oppoſite to Port St Mary on the continent, about ſixty miles ſouth-weſt of Seville, and forty north-weſt of Gibraltar: W. long. 6° 40, N. lat. 36° 30′.

The iſland it ſtands on is in length about eighteen miles; the ſouth-weſt end is about nine broad, but the other end, where the city ſtands, not above two. It has a communication with the continent by means of a bridge; and, with the oppoſite ſhore, forms a bay of twelve miles long and ſix broad. About the middle of this bay, there are two head-lands, or promontories, one on the continent, and the other on the iſland, which advance ſo near together, that the forts upon them, called the Puntal and Matagorda, command the paſſage; and within theſe forts is the harbour, which it is impoſſible for an enemy to enter till he has firſt taken the forts.

CADIZADELITES, a ſect of Mahometans very like the ancient ſtoics. They ſhun feaſts and diverſions, and affect an extraordinary gravity in all their actions; they are continually talking of God, and ſome of them make a jumble of Chriſtianity and Mahometaniſm; they drink wine, even in the faſt of the ramazan; they love and protect the Chriſtians; they believe that Mahomet is the Holy Ghoſt, practiſe circumciſion, and juſtify it by the example of Jeſus Chriſt.

CADMIA, a metallic ſubſtance ſeparated from the ore of zinc by fuſion. See CHEMISTRY, *Of zinc.*

CADORIN, a province of Italy, in the territories of Venice, bounded by the biſhopric of Brixen on the north;

north; by Friuli, on the eaſt; by the Bellunese, on the ſouth; and by the Trentin, on the weſt.

CADRITES, a ſort of Mahometan friars, who once a-week ſpend great part of the night in turning round, holding each other's hand, and repeating inceſſantly the word *hai*, which ſignifies living, and is one of the attributes of God; during which one of them plays on a flute. They never cut their hair, nor cover their heads, and always go bare footed; they have liberty to quit their convent when they pleaſe, and to marry.

CADSAND, an iſland on the coaſt of Dutch Flanders, ſituated at the mouth of the Scheld, whereby the Dutch command the navigation of that river.

CADUCEUS, in antiquity, Mercury's rod, or ſceptre, being a wand entwiſted by two ſerpents, borne by that deity, as the enſign of his quality and office, given him, according to the fable, by Apollo, for his ſeven-ſtringed harp.

Wonderful properties are aſcribed to this rod by the poets, as laying men aſleep, raiſing the dead, *&c.* It is uſed alſo as a ſymbol of peace. The caduceus, as found on ſome medals, is a common ſymbol, ſignifying good conduct, peace, and proſperity.

CADUS, in antiquity, a wine-veſſel of a certain capacity, containing eighty amphoræ, or firkins, each of which, according to the beſt accounts, held nine gallons.

CÆCILIA, in zoology, a genus of ſerpents belonging to the amphibia claſs. The cæcilia has no ſcales; it is ſmooth, and moves by means of lateral rugæ or prickles. The upper lip is prominent, and furniſhed with two tentacula. It has no tail. There are but two ſpecies of this ſerpent, viz. 1. The tentaculata, has 135 rugæ. It is about a foot long and an inch in circumference, preſerving an uniform cylindrical ſhape from the one end to the other. The teeth are very ſmall. It has ſuch a reſemblance to an eel, that it may eaſily be miſtaken for one; but as it has neither fins nor gills, it cannot be claſſed with the fiſhes. It is a native of America, and its bite is not poiſonous. 2. The glutinoſa has 340 rugæ or prickles above and ten below the anus. It is of a browniſh colour, with a white line on the ſide, and is a native of the Indies.

CÆCUM, or Coecum, in anatomy, the blind-gut. See p. 260. col. 2.

CÆMENT, in a general ſenſe, any glutinous ſubſtance, capable of uniting and keeping things together in cloſe coheſion: in this ſenſe, under cæment, are comprehended mortar, ſolder, glue, *&c.* but, ſtrictly ſpeaking, the term cæment only denotes a glutinous compoſition, uſed in cæmenting broken glaſſes, china-ware, or earthen-ware.

One of the fineſt, and at the ſame time ſtrongeſt cæment for this purpoſe, is the juice of garlic ſtamped in a ſtone mortar: this, if the operation is done with care, leaves little or no mark. Another cæment is made by beating the white of an egg very clear, and mixing with it fine powdered quick-lime: or iſing-glaſs, powdered chalk, and a little lime may be mixed together, and diſſolved in fair water. With theſe, the glaſſes, *&c.* are to be cæmented, and then ſet in the ſhade to dry; a caution which ſhould always be obſerved, whichever of the above cæments is uſed.

A cæment for cracked chemical-glaſſes, that will ſtand the fire, may be thus prepared: take wheat flour, fine powdered Venice glaſs, and pulverized chalk, of each an equal quantity; of fine brick-duſt, one half of the ſaid quantity; and a little ſcraped lint: mix them all together with the whites of eggs; then, ſpreading this mixture upon a linen cloth, apply it to the cracks of the glaſſes, which muſt be well dried before they are uſed. Old varniſh is another cæment that will anſwer the ſame purpoſe.

Cæment, among builders, a ſtrong ſort of mortar, uſed to bind bricks or ſtones together for ſome kind of mouldings; or in cæmenting a block of bricks for the carving of capitals, ſcrolls, or the like. There are two ſorts, 1. Hot cæment, which is the moſt common, made of reſin, bees-wax, brick-duſt, and chalk, boiled together. The bricks to be cæmented with this kind, muſt be made hot with the fire, and rubbed to and fro after the cæment is ſpread, in the ſame manner as joiners do when they glue two boards together. 2. Cold cæment, made of Cheſhire-cheeſe, milk, quick-lime, and whites of eggs. This cæment is leſs uſed than the former, and is accounted a ſecret known but to few bricklayers.

Cæment, among engravers, jewellers, *&c.* a compoſition of fine brick-duſt well ſifted, reſin, and bees-wax, in uſe among theſe artificers to keep the metals to be engraven or wrought on firm to the block; and alſo to fill up what is to be cheſſeled.

Cæment, in chemiſtry, a kind of menſtruum compounded of ſalts, ſulphurs, and brick, reduced to dry powders, and ſtrewed betwixt plates of metal, in order to raiſe their colour, or ſeparate one metal from another. See Chemistry.

Cæment-pots, or thoſe uſed in the cæmentation of metals, are made of fine potter's clay, and that either pure, or mixed with ſand in different proportions.

CÆMENTATION, in a general ſenſe, the corroding of metals in a dry form, by means of the fumes of acid ſalts. See Chemistry, Part II.

CAEN, the capital of a county of the ſame name in Normandy, ſituated on the river Orne, about ſeventy-five miles weſt of Rouen, and thirty ſouth-weſt of Havre de Grace: W. long. 25′, N. lat. 49° 20′.

It has an univerſity, firſt founded by king Henry VI. of England, in 1431.

CAERFILLY, a town of Glamorganſhire, about five miles north of Landaff: W. long. 3° 15′, and N. lat. 51° 35′.

CÆRITES, or Cæritum tabulæ, in Roman antiquity, tables or regiſters in which the names of the Cærites were regiſtered. The people of Cære were accounted citizens of Rome, but had no privilege of voting; hence when a Roman citizen was degraded, if a ſenator, he was expelled the ſenate; if a knight, he loſt the public horſe; and if a plebeian, his name was inſerted in the regiſter of the Cærites; that is, he was

was ſubject to all taxes, but incapable of voting or enjoying any public office.

CAERLEON, a market-town of Monmouthſhire, ſituated on the river Uſke, about ſixteen miles ſouth-weſt of Monmouth: W. long. 3°, N. lat. 51° 40′.

CAERMARTHEN, the capital of Caermarthenſhire in Wales, ſituated upon the river Tivy, about five miles from the ſea.

CAERNARVAN, the chief town of Caernarvanſhire in Wales, ſituated upon the river Menay.

CAERWIS, a market-town in Flintſhire, in north Wales, about five miles eaſt of St Aſaph, and four weſt of Flint: W. long. 3° 25′, N. lat. 53° 20′.

CÆSALPINIA, in botany, a genus of the decandria monogynia claſs. The calix has five ſegments, the loweſt of which is largeſt; the corolla conſiſts of five petals; the capſule is of the pod kind. There are four ſpecies, all natives of the Indies.

CÆSALPINOIDES, in botany, a ſynonime of the gleditſia. See GLEDITSIA.

CÆSAR, in Roman antiquity, a title borne by all the emperors, from Julius Cæſar, to the deſtruction of the empire. It was alſo uſed as a title of diſtinction, for the intended or preſumptive heir of the empire, as King of the Romans is now uſed for that of the German empire.

This title took its riſe from the ſurname of the firſt emperor, C. Julius Cæſar, which, by a decree of the ſenate, all the ſucceeding emperors were to bear. Under his ſucceſſor, the appellation of Auguſtus being appropriated to the emperors, in compliment to that prince, the title Cæſar was given to the ſecond perſon in the empire, though ſtill it continued to be given to the firſt; and hence the difference betwixt Cæſar uſed ſimply, and Cæſar with the addition of Imperator Auguſtus.

The dignity of Cæſar remained the ſecond of the empire, till Alexius Comnenus having elected Nicephorus Meliſſenus Cæſar, by contract; and it being neceſſary to confer ſome higher dignity on his own brother Iſaacius, he created him Sebaſtocrator, with the precedency over Meliſſenus; ordering, that in all acclamations, *&c.* Iſaacius Sebaſtocrator ſhould be named the ſecond, and Meliſſenus Cæſar, the third.

CÆSARIAN operation, in midwifery. See MIDWIFERY.

CÆSARIANS, *cæſarienſes*, in Roman antiquity, were officers or miniſters of the Roman emperors: They kept the account of the revenues of the emperors, and took poſſeſſion, in their name, of ſuch things as devolved, or were confiſcated to them.

CÆSTUS, in antiquity, a large gantlet made of raw hide, which the wreſtlers made uſe of when they fought at the public games.

This was a kind of leathern ſtrap, ſtrengthened with lead, or plates of iron, which encompaſſed the hand, the wriſt, and a part of the arm, as well to defend theſe parts, as to enforce their blows.

CÆSTUS, or CÆSTUM, was alſo a kind of girdle, made of wool, which the huſband untied for his ſpouſe the firſt day of marriage, before they went to bed.

This relates to Venus's girdle, which Juno borrowed of her, to entice Jupiter to love her. See CESTUS.

CÆSURA, in the ancient poetry, is when, in the ſcanning of a verſe, a word is divided ſo, as one part ſeems cut off, and goes to a different foot from the reſt; as,

Menti|ri no|li, nun|quam men|dacia| proſunt.

where the ſyllables *ri*, *li*, *quam*, and *men*, are cæſuras.

CÆSURE, in the modern poetry, denotes a reſt, or pauſe, towards the middle of an Alexandrian verſe, by which the voice and pronunciation are aided, and the verſe, as it were, divided into two hemiſtichs. See PAUSE.

CAFFA, in commerce, painted cotton-cloths manufactured in the E. Indies, and ſold at Bengal.

CAFFA, or KAFFA, a city and port-town of Crim Tartary, ſituated on the ſouth-eaſt part of that peninſula: E. long. 37°, N. lat. 44° 55′.

It is the moſt conſiderable town in the country, and gives name to the ſtraits of Caffa, which run from the Euxine or Black ſea, to the Palus Meotis, or ſea of Azoph.

CAFFILA, a company of merchants or travellers, who join together in order to go with more ſecurity thro' the dominions of the Grand Mogul, and through other countries on the continent of the E. Indies.

The Caffila differs from a caravan, at leaſt in Perſia; for the caffila belongs properly to ſome ſovereign, or to ſome powerful company in Europe; whereas a caravan is a company of particular merchants, each trading upon his own account. The Engliſh and Dutch have each of them their caffila at Gambron.

CAFFILA on the coaſt of Guzerat or Cambaya, ſignifies a ſmall fleet of merchant-ſhips.

CAFFRARIA, the country of the Caffers, or Hottentots, in the moſt ſoutherly part of Africa, lying in the form of a creſcent about the inland country of Monomotapa, between 35° S. lat. and the tropic of Capricorn; and bounded on the eaſt, ſouth, and weſt, by the Indian and Atlantic oceans.

Moſt of the ſea-coaſts of this country are ſubject to the Dutch, who have built a fort near the moſt ſouthern promontory, called the Cape of Good-Hope.

CAG, or KEG, a barrel or veſſel, that contains from four to five gallons.

CAGE, an incloſure made of wire, wicker, or the like, interwoven lattice-wiſe, for the confinement of birds, or wild beaſts.

The cage, in the Roman amphitheatres, was a place wherein ſavage animals were confined. It was incloſed with iron rails, and open at top, ſo as to be ſeen to the bottom by the ſpectators.

CAGLI, a town of the province of Urbino, in the pope's territories, about twenty-five miles ſouth of the city of Urbino: E. long. 14°, N. lat. 43° 15′.

CAGLIARI, the capital of the iſland of Sardinia, ſituated on a bay of the ſea in the ſouthern part of that iſland: E. long. 9° 12′, N. lat. 39°.

CAGUI, in zoology, a ſynonime of two ſpecies of monkey, *viz.* the jaccchus and œdipus. See SIMIA.

CAHERAH,

CAHERAH, or AL-CAHERAH, the capital of Egypt, which we call Grand Cairo. See CAIRO.

CAHLO, the name by which ſome call the lupus piſcis or wolf-fiſh.

CAHORS, the capital of the territory of Querci, in the province of Guienne in France, ſituated about forty-five miles north of Tholouſe: E. long. 1°, N. lat. 44° 25′.

It is the ſee of a biſhop, and has an univerſity.

CAHYS, a dry meaſure for corn, uſed in ſome parts of Spain, particularly at Seville and at Cadiz. It is near a buſhel of our meaſure.

CAJANABURG, the capital of the province of Cajania, or eaſt Bothnia in Sweden, ſituated on the north-eaſt part of the lake Cajania, about three hundred miles north-eaſt of Abo: E. long. 27°, N. lat. 63° 50′.

CAJAZZO, a town of the province of Lavoro in the kingdom of Naples, ſituated about ſixteen miles north-eaſt of the city of Naples: E. long. 15°, N. lat. 41° 15′.

CAJEPUT, an oil brought from the E. Indies, which reſembles that of cardamoms.

CAIFUM, a city of China, ſituated in the province of Honan, on the river Crocceus, three hundred and fifty miles north-weſt of Nanking: E. long. 113° 30′, and N. lat. 35°.

CAIMACAN, or CAIMACAM, in the Turkiſh affairs, a dignity in the Ottoman empire, anſwering to lieutenant, or rather deputy, among us.

There are uſually two caimacans, one reſiding at Conſtantinople, as governor thereof; the other attending the grand vizir, in quality of his lieutenant, ſecretary of ſtate, and firſt miniſter of his council; and gives audience to ambaſſadors. Sometimes there is a third caimacan, who attends the ſultan; whom he acquaints with any public diſturbances, and receives his orders concerning them.

CAIMAN, or CAIMAN-ISLANDS, certain American iſlands lying ſouth of Cuba, and north-weſt of Jamaica, between 81° and 86° of W. long. and in 21° of N. lat.

They are moſt remarkable on account of the fiſhery of tortoiſe, which the people of Jamaica catch here, and carry home alive, keeping them in pens for food, and killing them as they want them.

CAINIANS, or CAINITES, in church-hiſtory, Chriſtian heretics, that ſprung up about the year 130, and took their name from Cain, whom they looked upon as their head and father: They ſaid, that he was formed by a celeſtial and almighty power, and that Abel was made but by a weak one.

This ſect adopted all that was impure in the hereſy of the gnoſtics, and other heretics of thoſe times: They acknowledged a power ſuperior to that of the Creator; the former they called *Wiſdom*, the latter, *Inferior Virtue*: They had a particular veneration for Korah, Abiram, Eſau, Lot, the Sodomites, and eſpecially Judas, becauſe his treachery occaſioned the death of Jeſus Chriſt: They even made uſe of a goſpel, which bore that falſe apoſtle's name.

CAINITO, in botany. See CHRYSOPHYLLUM.

CAIRO, or GRAND CAIRO, the capital of Egypt, ſituated in a plain at the foot of a mountain, about two miles eaſt of the Nile, and 100 miles ſouth of the mouth of that river: E. long. 32°, N. lat. 30°.

The town is ten miles in circumference, and full of inhabitants. The caſtle ſtands on the ſummit of a hill, at the ſouth end of the town, and is three miles round. The Britiſh and other European ſtates have their conſuls and factors here, for the protection of trade.

CAIROAN, a town of the kingdom of Tunis in Africa, ſituated on the river Magrida, about eighty miles ſouth of Tunis: E. long. 9°, N. lat. 36°.

CAINS, a name given to the Greeks in the iſle of Crete, who revolt from the Turks to the Venetians.

CAISSON, in the military art, a wooden cheſt, into which ſeveral bombs are put, and ſometimes only filled with gun-powder: This is buried under ſome work whereof the enemy intends to poſſeſs themſelves, and, when they are maſters of it, is fired, in order to blow them up.

CAISSON is alſo uſed for a wooden frame or cheſt, uſed in laying the foundations of the piers of a bridge.

CAITHNESS. See CATHNESS.

CAKILE, in botany. See BUNIAS.

CALABA, in botany. See CALOPHYLLUM.

CALABASH-*tree*, in botany. See CRESCENTIA.

CALABRIA, the moſt ſoutherly part of the kingdom of Naples, ſituated over againſt Sicily.

There are two provinces of Calabria called the Hither and Farther Calabria, with reſpect to the city of Naples; Coſenza being the capital of the former, and Rheggio of the latter.

CALADE, in the menage, the deſcent or ſloping declivity of a riſing menage ground, being a ſmall eminence upon which we ride down a horſe ſeveral times, putting him to a ſhort gallop, with his fore-hams in the air, to make him learn to ply or bend his haunches, and form his ſtop upon the aids of the calves of the legs, the ſtay of the bridle, and the caveſon ſeaſonably given.

CALAHORRA, a city of Old Caſtile in Spain, ſituated on the river Ebro, near the confines of Navarre, about ſixty miles north-weſt of Saragoſſa: W. long. 2°, N. lat. 42° 20′.

CALAIS, a port-town of Picardy in France, ſituated on the Engliſh channel, about twenty-two miles ſouth-eaſt of Dover: E. long. 2°, N. lat. 51°.

CALAMANCO, a ſort of woolen ſtuff manufactured in England and in Brabant. It has a fine gloſs, and is chequered in the warp, whence the checks appear only on the right ſide. Some calamancos are quite plain, others have broad ſtripes adorned with flowers; ſome with plain broad ſtripes, ſome with narrow ſtripes, and others watered.

CALAMINARIS, or LAPIS CALAMINARIS, in natural hiſtory, a kind of foſſil, the general ore of zinc, of a ſpungy ſubſtance and a lax and cavernous texture, yet conſiderably heavy.

It is of no determinate ſhape or ſize, but is found in maſſes of a very various and irregular figure. It is,

when

when moſt pure and perfect, of a pale browniſh grey. It is found in Germany, Saxony, Bohemia, and England. See CHEMISTRY, *Of zinc*.

After roaſting the calamine, in order to purge it of ſulphureous or arſenical matter, it is uſed by phyſicians in collyria againſt defluxions of thin acrid humours upon the eyes, for drying up moiſt running ulcers, and healing excoriations.

CALAMINT, in botany. See MELISSA, and MENTHA.

CALAMITA, in natural hiſtory, a name given to ſtyrax. See STYRAX.

CALAMITA is ſometimes alſo uſed for the magnet or load-ſtone.

CALAMITES. See OSTEOCOLLA.

CALAMUS, in botany, a genus of the hexandria monogynia claſs. The calix has ſix leaves; it has no corolla; the berry is imbricated, and contains but one ſeed. There is but one ſpecies, *viz.* the rotang, a native of India.

CALAMUS *aromaticus*, or ſweet-ſcented flag, in the materia medica, a ſpecies of flag called acorus by Linnæus. See ACORUS. The root is generally looked upon as a carminative and ſtomachic medicine, and as ſuch is ſometimes uſed in practice.

CALAMUS *ſcriptorius*, in antiquity, a reed or ruſh to write with.

The ancients made uſe of ſtyles to write on tables covered with wax; and of reed, or ruſh, to write on parchment, or Egyptian paper.

CALANGAY, in ornithology. See PSITTACUS.

CALASH, or CALESH, a light and very low kind of chariot, uſed chiefly for taking the air in parks and gardens.

CALASIRIS, in antiquity, a linen tunic fringed at the bottom, and worn by the Egyptians under a white woolen garment; but this laſt they were obliged to pull off when they entered the temples, being only allowed to appear then in linen habits.

CALATAJUD, a city of Aragon, in Spain, ſituated on the river Xalo, about fifty miles weſt of Saragoſſa: W. long. 2° 5′, N. lat. 41° 15′.

CALATHUS, in antiquity, a baſket, hamper, or pannier of oſiers, reeds, or twigs, for women to put their work in, or to gather flowers in.

CALATHUS was alſo a veſſel, or pan, for cheeſe-curds and milk; alſo the name of a cup for wine, uſed in ſacrifices.

CALATOR, in antiquity, was a public ſervant, and a freeman, ſuch as a bailiff or crier, a ſumner, to ſummon courts, ſynods, and other public aſſemblies.

CALATRAVA, a city of new Caſtile, in Spain, ſituated on the river Guadiana, forty-five miles ſouth of Toledo: W. long. 4° 20′, N. lat. 39°.

Knights of CALATRAVA, a military order in Spain, inſtituted under Sancho III. king of Caſtile, upon the following occaſion. When that prince took the ſtrong fort of Calatrava from the moors of Andaluſia, he gave it to the templars, who, wanting courage to defend it, returned it him again. Then Don Reymond, of the order of the Ciſtercians, accompanied with ſeveral perſons of quality, made an offer to defend the place, which the king thereupon delivered up to them, and inſtituted that order. It increaſed ſo much under the reign of Alphonſus, that the knights deſired they might have a grand maſter, which was granted. Ferdinand and Iſabella afterwards, with the conſent of pope Innocent VIII. reunited the grand maſterſhip of Calatrava to the Spaniſh crown; ſo that the kings of Spain are now become perpetual adminiſtrators thereof.

The knights of Calatrava bear a croſs gules, fluerdeliſed with green, *&c.* their rule and habit was originally that of the Ciſtercians.

CALCADA, or St DOMINGO DE CALCADA, a city of Old Caſtile, in Spain, forty-eight miles eaſt of Burgos: W. long. 3°, N. lat. 42° 36′.

CALCANEUM, or OS CALCIS, in anatomy. See p. 186. col. 1.

CALCAR, in zoology, the trivial name of a ſpecies of nautilus. See NAUTILUS.

CALCAR, in glaſs-making, a ſort of oven, or reverberatory furnace, in which, being well heated, the cryſtal frit, or bollito, is made.

CALCAR, in geography, a town of the duchy of Cleves, and circle of Weſtphalia, in Germany: E. long. 5° 50′, and N. lat. 51° 45′.

CALCARIOUS, in general, denotes ſomething belonging to, or partaking of the nature of calx. See CALX.

CALCARIUS *lapis*, in natural hiſtory, the ſame with lime-ſtone. See LIME.

CALCEARIUM, in antiquity, a term uſed to denote the allowance made the ſoldiers to buy their ſhoes.

CALCEOLUS, in botany. See CYPRIPEDIUM.

CALCINATION, in chemiſtry, the reducing of ſubſtances to a calx by fire. See CHEMISTRY.

CALCITRAPA, and CALCITRAPOIDES, in botany. See CENTAUREA.

CALCULUS, in natural hiſtory, properly denotes a little ſtone or pebble. See PEBBLE.

CALCULUS, or CALCULUS HUMANUS, in medicine, the ſtone in the bladder or kidneys. See MEDICINE, and SURGERY.

CALCULUS alſo denotes a method of computation, ſo called from the calculi, or counters, anciently uſed for this purpoſe. Hence,

CALCULUS SPECIALIS, or LITERALIS, is the ſame with algebra. See ALGEBRA.

CALCULUS *differentialis* is a method of differencing quantities, that is, of finding an infinitely ſmall quantity, which being taken an infinite number of times, ſhall be equal to a given quantity. See FLUXIONS.

CALCULUS *exponentialis*, among mathematicians, a method of differencing exponential quantities, and ſumming up the differentials of exponential quantities. See FLUXIONS.

CALCULUS INTEGRALIS, or SUMMATORIUS, is a method of ſumming up differential quanties; that is, from a differential quantity given, to find the quantity from whoſe differencing the given differential reſults. See FLUXIONS.

CALDARIUM, in the ancient baths, a certain vault, or

or room, made ſo as to collect the vapours, and produce ſweating: whence it ſignifies a hot houſe, bagnio, ſtove, or ſweating-room.

CALEFACTION, the production of heat in a body from the action of fire, or that impulſe impreſſed by a hot body upon other bodies about it. This word is uſed in pharmacy, by way of diſtinction from coction, which implies boiling; whereas calefaction is only heating a thing.

CALENBURG-CASTLE, the capital of a duchy of the ſame name, in Lower Saxony, in Germany, ſituated upon the river Leine, about fifteen miles ſouth of Hanover: E. long. 9° 40′, and N. lat. 52° 20′.

CALENDAR, a diſtribution of time, accommodated to the various uſes of life, but more eſpecially ſuch as regard civil and eccleſiaſtical polity. See ASTRONOMY, *Of the diviſion of time.*

Julian Chriſtian CALENDAR. See ASTRONOMY, *Of the diviſion of time.*

Gregorian CALENDAR. See ASTRONOMY, *Of the diviſion of time.*

CALENDER, a machine uſed in manufactories, to preſs certain woollen and ſilken ſtuffs, and linens, to make them ſmooth, even, and gloſſy, or to give them waves, or water them, as may be ſeen in mohairs and tabbies. This inſtrument is compoſed of two thick cylinders, or rollers, of very hard and poliſhed wood, round which the ſtuffs to be calendered are wound: theſe rollers are placed croſs-ways between two very thick boards, the lower ſerving as a fixed baſe, and the upper moveable, by means of a thick ſcrew, with a rope faſtened to a ſpindle, which makes its axis: the uppermoſt board is loaded with large ſtones weighing 20000 lb. or more. It is this weight that gives the poliſh and makes the waves on the ſtuffs about the rollers, by means of a ſhallow indenture or engraving cut in it.

CALENDS, in Roman antiquity, the firſt day of each month, ſo called from the Greek [*kalein*], to proclaim: it being cuſtomary, on thoſe days, to proclaim the number of holy-days in each month.

The Roman method of reckoning the days of their months has ſomething extremely ſingular in it: inſtead of computing forwards, in the natural order of the numbers 1, 2, 3, *&c.* they reckoned backwards, in the manner expreſſed in the following verſes:

Prima dies menſis cujuſque eſt dicta calendæ:
Sex Maius, nonas, *Julius*, *October*, *& Mars*;
Quatuor at reliqui: habet idus *quilibet octo*;
Inde dies reliquos omnes dic eſſe calendas;
Quas retro numerans, dices a menſe ſequente.

Hence to find the day of our month anſwering to that of the calends, to the number of days in the preceding month add two, and from this ſum ſubtracting the number of calends given, the remainder will be the day of our month: thus the fourth of the calends of June is found to anſwer to the twenty-ninth of May; and ſo in other caſes.

CALENDULA, or MARYGOLD, in botany, a genus of the ſyngeneſia polygamia neceſſaria claſs. The receptacle is naked; it has no pappus; the calix conſiſts of many equal leaves; the ſeeds of the diſk are membranaceous. There are eight ſpecies, none of them natives of Europe. The flowers of the calendula officinalis, or garden marygold, are ſaid to be aperient and attenuating, as alſo cordiac, alexipharmic, and ſudorific. They are principally celebrated in uterine obſtructions, and for throwing out the ſmall pox.

CALF, in zoology, the young of the ox-kind. See BOS.

Among ſportſmen, the term calf is uſed for a hart or hind of the firſt year: the ſame term is alſo uſed for the young of the whale.

Sea CALF. See PHOCA.

CALF'S-*ſnout*, in botany. See ANTIRRHINUM.

CALIACA, a town of Bulgaria, ſituated upon the Black-ſea, belonging to the Turks.

CALIBER, or CALIPER, properly denotes the diameter of any body: thus we ſay, two columns of the ſame caliber, the caliber of the bore of a gun, the caliber of a bullet, *&c.*

CALIBER-*compaſſes*, the name of an inſtrument, made either of wood, iron, ſteel, or braſs: that uſed for meaſuring bullets conſiſts of two branches, bending inwards, with a tongue fixed to one of them, and the other graduated in ſuch a manner, that if the bullet be compreſſed by the ends of the two branches, and the tongue be applied to the graduated branch, it will ſhew the weight of the bullet.

CALIBER alſo ſignifies an inſtrument uſed by carpenters, joiners, and bricklayers, to ſee whether their work be well ſquared.

CALICUT, a town ſituated on the Malabar coaſt, in the hither peninſula of India, ſubject to its own prince: E. long. 75°, and N. lat. 11° 20′.

This was the firſt port the Portugueſe made in India, after ſailing round the Cape of Good Hope.

CALIDUCT, in antiquity, a kind of pipes, or canals, diſpoſed along the walls of houſes and apartments, uſed, by the ancients, for conveying heat to ſeveral remote parts of the houſe, from one common furnace.

CALIFORNIA. See CALLIFORNIA.

CALIMUS. See CALLIMUS.

CALIN, a compound metal, whereof the Chineſe make tea-caniſters, and the like. The ingredients ſeem to be lead and tin.

CALIPH, the ſupreme eccleſiaſtical dignity among the Saracens; or, as it is otherwiſe defined, a ſovereign dignity among the Mahometans, veſted with abſolute authority in all matters relating both to religion and policy.

It ſignifies in the Arabic, ſucceſſor or vicar: the Saracen princes aſſumed this title as deſcendants from Mahomet; the caliphs bearing the ſame relation to Mahomet, that the popes pretend they do to Jeſus Chriſt or St Peter. It is at this day one of the grand ſignior's titles, as ſucceſſor of Mahomet; and of the ſophi of Perſia, as ſucceſſor of Ali.

CALIPPIC PERIOD, an improvement of the cycle of Meton, of nineteen years, which Calippus, a famous Grecian aſtronomer, finding in reality to contain nineteen

teen of Nabonaſſar's years, four days, and $\frac{311}{450}$, he, to avoid fractions, quadrupled the golden number, and by that means made a new cycle of ſeventy-ſix years; which time being expired, he ſuppoſed the lunation, or changes of the moon, would happen on the ſame day of the month, and hour of the day, that they were on ſeventy-ſix years before.

CALIX. See CALYX.

CALIXTINS, in church-hiſtory, a ſect of Chriſtians, in Bohemia and Moravia: the principal point in which they differed from the church, was the uſe of the chalice, or communicating in both kinds.

CALIXTINS, is alſo a name given to thoſe, among the Lutherans, who follow the ſentiments of George Calixtus, a celebrated divine, who oppoſed the opinion of St Auguſtine, on predeſtination, grace, and free-will.

CALKA, a kingdom of Tartary, in Aſia, to the eaſt of Siberia.

CALKING. See CAULKING.

CALKINS, the prominent parts at the extremities of a horſe-ſhoe, bent downwards, and forged to a ſort of point.

Calkins are apt to make horſes trip; they alſo occaſion blymes, and ruin the back ſinews. If faſhioned in form of a hare's ear, and the horn of a horſe's heel be pared a little low, they do little damage; whereas the great ſquare calkins quite ſpoil the foot.

Calkins are either ſingle or double, that is, at one end of the ſhoe, or at both: theſe laſt are deemed leſs hurtful, as the horſe can tread more even.

CALL, among hunters, a leſſon blown upon the horn, to comfort the hounds.

CALLS, *natural and artificial*, among fowlers, a ſport much practiſed during the wooing ſeaſon of partridges, eſpecially for taking cock-partridges; for which they put a hen into a cadge, to call and bring them near. The hen-partridge ſhould be ſet near a hedge, in a thin, open, wire-cage, ſo that ſhe may be ſeen at a good diſtance: then the net, called hallier, ſhould be placed quite round the cage, each part about the diſtance of twenty feet: the fowler ſhould retire behind the hedge.

Artificial CALLS are beſt made of box, walnut-tree, or the like: they are formed of the bigneſs of an hen's egg, bored through from end to end; about the middle there muſt be a hole hollowed within, to the bottom; then have a pipe of a ſwan's quill, and the bone of a cat's foot, opened at one end, which muſt be conveyed into the hole at the end, and ſo thruſt into the hole at the middle; take afterwards a gooſe-quill, opened at both ends, and put it in at the other end of the call; blow into the quill, and it will make the like noiſe as the partridge-cock does.

CALLA, in botany, a genus of the gynandria polyandria claſs. The ſpatha is plain; the ſpadix is covered with floſcules; it has no corolla; the berry contains many ſeeds. There are three ſpecies, none of them natives of Britain.

CALLABAS, a town of Indoſtan in Aſia, upon the road from Surat to Agra.

CALLAO, a port-town in a little iſland on the coaſt of Peru, in South America, oppoſite to Lima: W. long. 76°, and S. lat. 12°.

CALLEN, a town of Ireland, in the county of Kilkenny, and province of Leinſter, about ten miles ſouthweſt of Kilkenny: W. long. 7° 22′, and N. lat. 52° 25′.

CALLICHTYS, in ichthyology, the trivial name of a ſpecies of ſilurus. See SILURUS.

CALLICO, in commerce, a kind of linen manufacture, made of cotton, chiefly in the Eaſt Indies, ſome of which are painted with various flowers of different colours; and others that are never dyed, having a ſtripe of gold and ſilver quite through the piece; and at each end they fix a tiſſue of gold, ſilver, and ſilk, intermixed with flowers. This manufacture is brought hither by the Eaſt-India company, and is re-exported by merchants to other parts of Europe. The general wear of ſtained or printed India calicoes in this nation having become a general grievance, and occaſioning unſpeakable diſtreſs upon our own manufacturers, they were prohibited by ſtat. 7 Geo. I. cap. vii.

CALLIDRYS, in ornithology, the trivial name of a ſpecies of motacilla. See MOTACILLA.

CALLIFORNIA, a large country of the Weſt Indies, lying between 116° and 138° W. long. and between 23° and 46° N. lat. It is uncertain whether it be a peninſula or an iſland.

CALLIGONUM, in botany, a genus of the polyandria digynia claſs. The calix has five leaves; the petals are four; it has two ſtyli; and the capſule is divided into two partitions, each containing two ſeeds. There is but one ſpecies, *viz.* the polygonoides, a native of mount Ararat.

CALLIGRAPHUS, in antiquity, a copiſt or ſcriviner, who tranſcribed, in a fair hand, what the notaries had taken down in notes, or minutes, being generally in a kind of cypher or ſhort-hand, which, as they were in that hand, being underſtood by few, were copied over fair and at length by perſons who had a good hand, for ſale, *&c.*

CALLING *the houſe*, in the Britiſh parliament, is the calling over the members names, every one anſwering to his own, and going out of the houſe, in the order in which he is called: this they do, in order to diſcover whether there be any perſons there not returned by the clerk of the crown; or if any member be abſent without leave of the houſe.

CALLIONYMUS, in ichthyology, a genus of fiſhes belonging to the order of jugulares. The upper lip is doubled up; the eyes are very near each other; the membrane of the gills has ſix radii; the operculum is ſhut; the body is naked; and the belly-fins are at a great diſtance from each other. There are three ſpecies of callionymus, *viz.* 1. The lyra, with the firſt bone of the back-fin as long as the body of the animal, and a cirrhus at the anus. It is of the Atlantic. 2. The dracunculus, with the firſt bone of the back-fin ſhorter than its body; which is of a ſpotted yellow colour. It frequents the ſhores of Genoa and Rome. 3. The indicus, has a ſmooth head with longitudinal wrinkles; the lower jaw is a little longer than the upper

per

per one; the tongue is obtuſe and emarginated; the apertures of the gills are large: it is of a livid colour, and the anus is in the middle of the body. It is a native of Aſia.

CALLISTEA, in Grecian antiquity, a Leſbian feſtival, wherein the women preſented themſelves in Juno's temple, and the prize was aſſigned to the faireſt. There was another of theſe contentions at the feſtival of Ceres Eleuſinia, among the Parrhaſians, and another among the Eleans, where the moſt beautiful man was preſented with a complete ſuit of armour, which he conſecrated to Minerva, to whoſe temple he walked in proceſſion, being accompanied with his friends, who adorned him with ribbands, and crowned him with a garland of myrtle.

CALLOSUM *corpus*, in anatomy. See p. 285. c. 2.

CALLUS, or CALLOSITY, in a general ſenſe, any cutaneous, corneous, or oſſeous hardneſs, whether natural or preternatural: but moſt frequently it means the callus generated about the edges of a fracture, provided by nature to preſerve the fractured bones, or divided parts, in the ſituation in which they are replaced by the ſurgeon.

CALM, in the ſea-language, is when there is no wind ſtirring.

That tract of ſea, to the northward of the equator, between 4° and 10° of latitude, lying between the meridians of Cape Verde, and of the eaſtermoſt iſland of that name, ſeems to be a place condemned to perpetual calms: the little winds that are being only ſome ſudden uncertain guſts of very ſmall continuance, and leſs extent. The Atlantic ocean, near the equator, is very much ſubject, nay, always attended with theſe calms.

CALMAR, the capital of the province of Gothland, in Sweden, ſituated on the coaſt of the Baltic ſea, about forty miles north of Carelſcroon: E. long. 16°, and N. lat. 56° 40′.

CALMUCKS, certain wandering tribes or hords of Tartars, inhabiting the country north of the Caſpian ſea, under the protection of Ruſſia

CALNE, a borough-town of Wiltſhire, about twenty miles north of Saliſbury, which ſends two members to parliament: W. long. 2°, and N. lat. 51° 30′.

CALOGERI, in church-hiſtory, monks of the Greek church, divided into three degrees, the novices, called archari; the ordinary profeſſed, called michrochemi; and the more perfect, called megalochemi: they are likewiſe divided into cœnobites, anchorets, and recluſes. The cœnobites are employed in reciting their office from midnight to ſun-ſet; they are obliged to make three genuflexions at the door of the choir, and returning, to bow to the right and to the left, to their brethren. The anchorets retire from the converſation of the world, and live in hermitages, in the neighbourhood of the monaſteries; they cultivate a little ſpot of ground, and never go out but on Sundays and holy-days, to perform their devotions at the next monaſtery. As for the recluſe, they ſhut themſelves up in grottos and caverns, on the tops of mountains, which they never go out of, abandoning themſelves entirely to Providence: They live on the alms ſent them by the neighbouring monaſteries.

CALOMEL, or dulcified ſublimate of mercury, is prepared in the following manner. Take of corroſive ſublimate, one pound; purified quick ſilver, nine ounces. Having powdered the ſublimate, add to it the quick-ſilver, and digeſt them together in a matraſs, with a gentle ſand heat, until they unite; then increaſing the heat, let the mixture be ſublimed. The ſublimed matter, freed from the acrimonious part at top and ſuch mercurial globules as happen to appear diſtinct in it, is to be reduced into powder, and ſublimed again; and this ſublimation muſt be repeated ſix times. This dulcified mercury, or calomel, is one of the beſt preparations for general uſe. The doſe, for raiſing a ſalivation, is ten or fifteen grains, taken in the form of a bolus, or pills, every night or oftener, till the ptyaliſm begins. As an alterant and diaphoretic, it is given in doſes of five or ſix grains, a purgative being occaſionally interpoſed, to prevent its affecting the mouth. It anſwers however much better when given in ſmaller quantities, as one, two, or three grains every morning and evening, in conjunction with ſuch ſubſtances as determine its action to the ſkin, as the extract or reſin of guaicum; the patient at the ſame time keeping warm, and drinking freely of warm diluting liquors. By this method of managing it, obſtinate, cutaneous, and veneral diſtempers have been ſucceſsfully cured, without any remarkable increaſe of the ſenſible evacuations.

CALOPHYLLUM, in botany, a genus of the polyandria monogynia claſs. The corolla conſiſts of five petals; the calix has five teeth; and the drupa is globular. There are but two ſpecies, viz. the inophyllum, and calaba, both natives of India.

CALOTTE, a cap or coif of hair, ſatin, or other ſtuff: an eccleſiaſtical ornament in moſt popiſh countries. See CAP.

CALOTTE, in architecture, a round cavity or depreſſure, in form of a cap or cup, lathed and plaſtered, uſed to diminiſh the riſe or elevation of a moderate chapel, cabinet, alcove, *&c.* which, without ſuch an expedient, would be too high for other pieces of the apartment.

CALPE, the mountain, at the foot of which, towards the ſea, Gibraltar ſtands. It is half a league in height towards the land, and ſo ſteep, that there is no approaching it on that ſide.

CALQUING, or CALKING, a term uſed in painting, *&c.* where the backſide of any deſign is covered with a black or red colour, and the ſtrokes, or lines, traced through, on a waxed plate, wall, or other matter, by paſſing lightly over each ſtroke of the deſign with a point, which leaves an impreſſion of the colour on the plate or wall.

CALTHA, in botany, a genus of the polyandria polygynia claſs. It has no calix; there are five petals; and the capſules are many, containing a great number of ſeeds. There is but one ſpecies, viz. the paluſtris, or marſh-marygold, a native of Britain.

CALTROP, in botany, the Engliſh name of the tribulus. See TRIBULUS.

CALVARIA,

CALVARIA, in anatomy, the hairy ſcalp. See p. 151.

Calvary, in heraldry, a croſs ſo called, becauſe it reſembles the croſs on which our Saviour ſuffered. It is always ſet upon ſteps.

CALVI, a town of the province of Lavoro, in the kingdom of Naples, ſituated near the ſea, about fifteen miles north of the city of Naples: E. long. 14° 45′, and N. lat. 41° 15′.

Calvi is alſo the name of a ſea-port in the iſland of Corſica, ſituated on a bay, on the weſt ſide of the iſland, about forty miles ſouth-weſt of Baſtia: E. long. 9° 5′, and N. lat. 42° 16.

CALVINISTS, in church-hiſtory, thoſe who follow the opinions of John Calvin, one of the principal reformers of the church, in the XVIth century, a perſon of great parts and induſtry, and of conſiderable learning; whoſe doctrine ſtill ſubſiſts in its greateſt purity at Geneva, where it was firſt broached, and from whence it was propagated. This is the prevailing religion of the United Provinces. In England, it is confined among the diſſenters; and, in Scotland, it is the only orthodox faith.

The Calviniſts are great advocates for the abſoluteneſs of God's decrees, and hold that election and reprobation depend on the mere will of God, without any regard to the merit or demerit of mankind; that he affords to the elect an irreſiſtible grace, a faith that they cannot loſe, which takes away the freedom of will, and neceſſitates all their actions to virtue.

The Calviniſts believe that God foreknew a determinate number, whom he pitched upon to be perſons, in whom he would manifeſt his glory; and that having thus foreknown them, he predeſtinated them to be holy, in order to which he gives them an irreſiſtible grace, which makes it impoſſible for them to be otherwiſe.

CALVITIES, or Calvitium, in medicine, baldneſs, or a want of hair, particularly on the ſinciput, occaſioned by the moiſture of the head, which ſhould feed it, being dried up, by ſome diſeaſe, old age, or the immoderate uſe of powder, *&c.* See Alopecia.

CALUMET, a ſymbol of peace among the Indians, in the north of America; It is made of a red ſtone, like our marble; the head reſembles our tobacco-pipes, but larger; and is fixed on a hollow reed, to hold it for ſmoking: They adorn it with fine wings of ſeveral colours, and is the calumet of the ſun, to whom they preſent it, eſpecially if they want fair weather, or rain. This pipe is a paſs and ſafe conduct amongſt all the allies of the nation who has it given: in all embaſſies the embaſſador carries it as an emblem of peace, and it always meets with a profound regard; for the ſavages are generally perſuaded, that a great misfortune would befal them, if they violated the public faith of the calumet.

CALX, properly ſignifies lime, but is alſo uſed by chemiſts and phyſicians for a fine powder remaining after the calcination or corroſion of metals and other mineral ſubſtances. See Chemistry.

Calx *antimonii.* See Chemistry, *Of antimony.*

Calx *nativa,* in natural hiſtory, a kind of marly earth, of a dead whitiſh colour, which, if thrown into water, makes a conſiderable bubbling and hiſſing noiſe, and has, without previous burning, the quality of making a cæment like lime, or plaſter of Paris.

Calx *viva,* or quick-lime, that whereon no water has been caſt, in contradiſtinction to lime which has been ſlaked by pouring water on it. See Chemistry, *Of lime.*

Calx, in anatomy. See Calcaneum.

CALYCISTÆ, an appellation given by Linnæus to thoſe botaniſts who have claſſed plants according to the different ſtructure of the calyx, or cup of the flower; ſuch was Magnolius.

CALYPTRA, among botaniſts, a thin membranaceous involucrum, uſually of a conic figure, which covers the parts of fructification. The capſules of moſt of the moſſes have calyptræ. See Botany.

CALYX, among botaniſts, a general term expreſſing the cup of a flower, or that part of a plant which ſurrounds and ſupports the other parts of the flower.

The cups of flowers are very various in their ſtructure, and on that account diſtinguiſhed by ſeveral names, as perianthium, involucrum, ſpatha, gluma, *&c.* See Botany.

CAM, a river, anciently called Grant, which, ariſing in Hertfordſhire, runs north-eaſt by Cambridge, and afterwards continues its courſe northwards, to the iſle of Ely, where it falls into the river Ouſe.

CAMÆA, in natural hiſtory, a genus of the ſemipellucid gems, approaching to the onyx ſtructure, being compoſed of zones, and formed on a cryſtalline baſis; but having their zones very broad and thick, and laid alternately on one another, with no common matter between; uſually leſs tranſparent, and more debaſed with earth, than the onyxes.

1. One ſpecies of the camæa is the dull-looking onyx, with broad black and white zones; and is the camæa of the moderns, and the Arabian onyx: This ſpecies is found in Egypt, Arabia, Perſia, and the Eaſt Indies. 2. Another ſpecies of the camæa is the dull, broad-zoned, green and white camæa, or the jaſpi-cameo of the Italians: It is found in the Eaſt Indies, and in ſome parts of America. 3. The third is the hard camæa, with broad white and cheſnut-coloured veins. 4. The hard camæa, with bluiſh, white, and fleſh-coloured broad veins, being the ſardonyx of Pliny's time, only brought from the Eaſt Indies.

CAMAIEU, a term in painting, when there is only one colour, the lights and ſhades being of gold, or on a golden and azure ground. It is chiefly uſed to repreſent baſſo-relievos.

CAMALDULIANS, a religious order founded by St Romauld, in a little plain, on the mount Apennine, called Camaldalia, ſituated in the ſtate of Florence.

The manner of life firſt enjoined this order was, that they dwelt in ſeparate cells, and met together only at the time of prayer: Some of them, during the two lents of the year, obſerved an inviolable ſilence; and others, for the ſpace of an hundred days. On Sundays and Thurſdays they fed on herbs, and the reſt of the

Plate LIX.

Fig. 3. BACTRIANUS or BACTRIAN CAMEL

Fig. 2. DROMADERICUS or AFRICAN CAMEL

Fig. 1. BRADYPUS or SLOTH

the week only on bread and water. These constitutions were, however, a little moderated some time afterwards. This hermitage is now accounted very rich.

CAMARA, in botany, See LANTANA.

CAMARANA, an island of Arabia in the Red sea, situated in 15° N. lat.

CAMBAIA, a city of the province of Cambaia, or Guzarat, in the higher peninsula of India; it is a very large city, and had once a great trade, now removed to Surat: E. long. 72°, and N. lat. 23° 30′.

CAMAYES, in commerce, cotton linens made at Bengal, at Madrass, and some other places on the coast of Coromandel.

CAMBER-*beam*, among builders, a piece of timber in an edifice, cut archwise, or with an obtuse angle in the middle, commonly used in platforms, as church-leads, and on other occasions where long and strong beams are required.

CAMBLET, or CAMLET, a plain stuff, composed of a warp and woof, which is manufactured on a loom, with two treddles, as linens and flannels are.

There are camblets of several sorts, some of goat's hair, both in the warp and woof; others, in which the warp is of hair, and the woof half hair and half silk; others again, in which both the warp and the woof are of wool; and lastly, some of which the warp is of wool and the woof of thread. Some are dyed in thread, others are dyed in the piece, others are marked or mixed; some are stripped, some weaved or watered, and some figured.

Camblets are proper for several uses, according to their different kinds and qualities; some serve to make garments both for men and women; some for bed-curtains; others for household-furniture, *&c.*

CAMBODIA, the capital of a kingdom of the same name in India, beyond the Ganges: E. long. 104°, N. lat. 12° 30′.

The kingdom of Cambodia extends from 9° to 15° of N. lat. being bounded by the kingdom of Laos on the north, Cochin-china on the east, the Indian ocean on the south, and by the bay of Siam on the west.

CAMBRAY, a city in the French Netherlands, situated on the river Schelde, near its source: E. long. 3° 15′, and N. lat. 50° 15′.

It is a large and well-built city, considerable for its linen manufacture, especially cambricks, which took their name from hence.

CAMBRICKS, a species of very fine white linen, made of flax at Cambray.

CAMBRIDGE, the capital of Cambridgeshire, situated upon the river Cam, about fifty-five miles north of London, and sixty north-east of Oxford.

Cambridge is most remarkable on account of its university, which consists of sixteen colleges, wherein are educated about fifteen hundred students. There are fourteen parishes in the town, which is said to contain about six thousand inhabitants.

New CAMBRIDGE, a town of New England, about three miles west of Boston; likewise remarkable for an university, consisting of three colleges: W. long. 70° 4′, and N. lat. 42°.

CAMEL, in zoology. See CAMELUS.

CAMELFORD, a borough-town of Cornwall, about twenty miles west of Launceston: W. long. 5°, and N. lat. 50° 40′.

It sends two members to parliament.

CAMELIA, in botany, a genus of the monodelphia polyandria class. The calix is imbricated, and consists of many leaves, the anterior of which are longest. There is but one species, *viz.* the japonica, a native of China and Japan.

CAMELOPARDALIS, in zoology, the trivial name of a species of cervus. See CERVUS.

CAMELUS, or CAMEL, in zoology, a genus of quadrupeds belonging to the order of pecora. The characters of the camel are these: It has no horns, it has six foreteeth in the under-jaw; the laniarii are wide set, three in the upper, and two in the lower jaw; and there is a fissure in the upper lip, resembling the cleft in the lip of a hare. The species are four, *viz.* 1. The dromedarius, or African camel, (Plate LIX. fig. 2.) with one bunch or protuberance on the back. It has four callous protuberances on the fore-legs, and two on the hind ones. The hoof, or rather callous skin of their feet, which is softer than the hoofs of other animals, enables the camel to walk along the sandy paths of warm climates with greater ease; by yielding to the pressure, it is not so subject to be injured by friction. The structure and constitution of the camel is admirably adapted to the climate which produces them. In Africa and Arabia, where this animal is most frequent, and is employed in carrying all kinds of burdens, there is great scarcity of water. The camel has often been observed to travel longer than any other creature without drink. This it is enabled to do, from a singular construction in its stomachs. It is one of the ruminating animals, and has four stomachs. At the top of the second stomach, there are several square holes, which are the orifices of about twenty cavities or sacks, placed between the two membranes which compose the substance of this stomach. These sacks are so many reservoirs which they fill over and above what satisfies their present thirst, and serve for supplying them with water in long journeys through the dry and sandy desarts, where wells or rivers are seldom to be met with. Travellers, when much oppressed with drought, are sometimes obliged to kill their camels, in order to have a supply of drink from these reservoirs. The camel carries very heavy burdens, and travels long, but with a slow pace. They have sometimes been known to travel several days without a fresh supply of water. When fatigued, they lie on their breast. 2. The Bactrianus, or Bactrian camel (fig. 3.), has two bunches on the back, the hindmost of which is by much the largest. It is a native of Africa, and is more rarely to be met with than the dromedary. It is also much swifter in its motion. 3. The glama, or South-American camel-sheep, has a smooth skin, and very short hair; it has a bunch or protuberance on the breast, which se-

cretes a liquor. They are very impatient of cold; are eafily tamed, and carry burdens of about fifty or fixty pounds weight. When reftive, they are pufhed on by fqueezing their tefticles. When enraged by their driver, they throw out from their mouth a liquor which corrodes and makes the fkin rife into blifters. 4. The pacos, or fheep of Chili, has no bunch on the back. It is covered with a fine valuable wool, which is of a blood-red colour on the back of the animal, and white on the belly. It is unfit for carrying burdens, and is kept principally for the fake of the wool, and the flefh, which is exceedingly well-tafted.

CAMERA *obfcura*, in optics, a machine reprefenting an artificial eye, wherein the images of external objects are exhibited diftinctly, in their native colours, either inverted or erect. See OPTICS.

CAMERARIA, in botany, a genus of the pentandria monogynia clafs. The flower of which is a petal of a funnel-form, with a cylindrical long tube, ventricofe both at the bafe and top, and a plane limb divided into five lanceolated fegments: The fruit is compofed of two oblong follicles, bent horizontally, obtufe at both ends, and fending out a lobe on each fide, near the bafe; they have one cell, with one valve, containing numerous, oval, and imbricated feeds, inferted in a large oval membrane at the bafe. There are two fpecies, *viz.* the latifolia, and anguftifolia, both natives of America.

CAMERATED, among builders, the fame with vaulted or arched.

CAMERET-BAY, in the province of Britany in France, forms the harbour of Breft. See BREST.

CAMERINO, a town of the ecclefiaftical ftate in Italy.

CAMERLINGO, according to Ducange, fignified formerly the pope's or emperor's treafurer: At prefent, camerlingo is nowhere ufed, but at Rome, where it notes the cardinal who governs the ecclefiaftical ftate, and adminifters juftice. It is the moft eminent office at the court of Rome, becaufe he is at the head of the treafury. During a vacation of the papal chair, the cardinal camerlingo publifhes edicts, coins money, and exerts every other prerogative of a fovereign prince; he has under him a treafurer-general, auditor-general, and twelve prelates called clerks of the chamber.

CAMERONIANS, a party of prefbyterians, which fprung up in Scotland in the reign of king Charles II. They affirmed that the king had forfeited his right to the crown, by breaking the folemn league and covenant, which were the terms on which he received it. They pretended both to dethrone and excommunicate him; and broke out into an open rebellion. Upon the revolution, they were reconciled to the kirk, and their preachers fubmitted to the general affembly of the church of Scotland, in 1690. That fect is now greatly declined. They are few in number, and fplit into many parties.

CAMERY, or FROUNCE, in horfes. See FROUNCE.

CAMILLI, and CAMILLÆ, in Roman antiquity, a certain number of boys and girls, who affifted in the facrifices to the gods, but more efpecially attended the flamen dialis.

CAMIS, or KAMIS, in the Japonefe affairs, denote the deified fouls of illuftrious perfonages, believed to intereft themfelves in the welfare of their countrymen: In which fenfe they anfwer to the deified heroes of antiquity. See HERO.

CAMISARDS, a name given by the French to the Calvinifts of the Cevennes, who formed a league, and took up arms in their own defence, in 1688.

CAMLETINE, a flight ftuff, made of hair and coarfe filk, in the manner of camblet. It is now out of fafhion.

CAMMIN, a port-town of Brandenburg-Pomerania in Germany, fituated on the eaftern mouth of the river Oder, about thirty miles north of Stetin: E. long. 15°, N. lat. 54°.

CAMP, the ground upon which an army pitch their tents. It is marked out by the quarter-mafter general, who appoints every regiment their ground.

The chief advantages to be minded in chufing a camp for an army, are, to have it near the water, in a country of forage, where the foldiers may find wood for dreffing their victuals; that it have a free communication with garrifons, and with a country from whence it may be fupplied with provifions; and, if poffible, that it be fituated on a rifing ground, in a dry gravelly foil. Befides, the advantages of the ground ought to be confidered, as marfhes, woods, rivers, and inclofures; and if the camp be near the enemy, with no river or marfh to cover it, the army ought to be intrenched. An army always encamps fronting the enemy; and generally in two lines, running parallel about five hundred yards diftance; the horfe and dragoons, on the wings, and the foot in the centre: Sometimes a body of two, three, or four brigades is encamped behind the two lines, and is called the body of referve. The artillery and bread-waggons are generally encamped in the rear of the two lines. A battalion of foot is allowed eighty or an hundred paces for its camp; and thirty or forty for an interval betwixt one battalion and another. A fquadron of horfe is allowed thirty for its camp, and thirty for an interval, and more if the ground will allow it.

The difpofition of the Hebrew encampment was at firft laid out by God himfelf. Their camp was of a quadrangular form, furrounded with an inclofure of the height of ten hands-breadth. It made a fquare of twelve miles in compafs about the tabernacle; and within this was another, called the Levites camp. The Greeks had alfo their camps, fortified with gates and ditches. The Lacedemonians made their camp of a round figure, looking upon that as the moft perfect and defenfible of any form: We are not, however, to imagine, that they thought this form fo effential to a camp, as never to be difpenfed with when the circumftance of the place required it. Of the reft of the Grecian camps, it may be obferved, that the moft valiant of the foldiers were placed at the extremities, the reft in the middle. Thus we learn from Homer, that

that Achilles and Ajax were posted at the ends of the camp before Troy, as bulwarks on each side of the rest of the princes.

The camps of the Romans were generally of an exact square form, or else oblong; though this, without doubt, was often accommodated to the situation of the place. They were always fortified, and a very exact discipline maintained in them, in order to prevent surprises from the enemy.

CAMP is also used, by the Siamese, and some other nations in the E Indies, as the name of the quarters which they assign to the foreigners who come to trade with them.

In these camps, every nation forms, as it were, a particular town, where they carry on all their trade, not only keeping all their ware-houses and shops there, but also live in these camps with their whole families. The Europeans, however, are so far indulged, that at Siam, and almost every where else, they may live either in the cities or suburbs, as they shall judge most convenient.

CAMPAGNA, in geography. See CAMPANIA.

CAMPAIGN, in the art of war, denotes the space of time that an army keeps the field, or is incamped, in opposition to quarters.

CAMPANIA, a city of the hither principate in the kingdom of Naples, situated about thirty-five miles south-east of the city of Naples: E. long. 15° 30′, N. lat. 4° 45′.

CAMPANIA, or CAMPAGNA DI ROMA, a province of the pope's territories in Italy, extending from the city of Rome south-east, as far as the frontiers of the kingdom of Naples.

CANPANIFORM, or CAMPANULATED, an appellation given to flowers resembling a bell.

CAMPANINI, a name given to a marble of Italy, dug out of the mountains of Carrara, because when it is worked it resounds like a bell.

CAMPANULA, or BELL-FLOWER, in botany, a genus of the pentandria monogynia class. The corolla is campaniform or bell-shaped, the bottom of which is closed with five valvulous nectaria; the stigma is trifid; and the capsule is below the flower, and opens at the sides. There are forty-one species of campanula, only nine of which are natives of Britain, *viz.* the rotundifolia, or lesser round-leaved bell flower; the patula, or field bell-flower; the uniflora, or mountain bell-flower; the rapunculus, or rampions; the latifolia, or giant throat-wort; the trachelium, great throat-wort, or Canterbury bells; and the glomerata, lesser throat-wort, or Canterbury-bells.

CAMPBELL-TOWN, a parliament town of Argyleshire in Scotland, situated on the eastern shore of Kintire, about ten miles west of the island of Arran: W. long. 5° 10′, N. lat. 55° 35′.

CAMPDEN, a market-town in Gloucestershire, about eighteen miles north-east of Gloucester: W. long. 1° 50′, and N. lat. 52°.

CAMPEACHY, or CAMPECHY, a town of the province of Jucatan, on the bay or gulf of Mexico: W. long. 93°, N. lat. 19°.

CAMPEACHY-WOOD, in botany. See HÆMATOXYLUM.

CAMPEN, a port-town, in the provine of Overyssel, in the united Netherlands, near the mouth of the river Issel, about forty-two miles north-east of Amsterdam: E. long. 5° 40′, and N. lat. 52° 35′.

CAMPHOR, or CAMPHIRE, a solid concrete juice extracted from the wood and roots of the laurus camphora, which grows in Japan. The camphor is extracted in the same way by which we extract essential oils. As it first sublimes from the wood, it appears brownish, composed of semipellucid grains mixed with dirt. In this state it is exported by the Dutch, and purified by a second sublimation; after which it is reduced to loaves, probably by fusion in close vessels, and in this form it is sold to us. Pure camphor is very white, pellucid, somewhat unctuous to the touch; of a bitterish, aromatic, acrid taste, yet accompanied with a sense of coolness. It has a fragrant smell, somewhat like that of rosemary, but much stronger. It is totally volatile and inflammable; soluble in vinous spirits, oils, and mineral acids; but not in water, alkaline liquors, or the vegetable acids. Camphor is esteemed one of the most efficacious diaphoretics, and has long been celebrated in fevers, malignant and epidemical distempers. In deliria, where opiates fail of procuring sleep, this medicine frequently succeeds.

Artificial CAMPHOR is prepared with gum-sandarach and white vinegar distilled, kept twenty days in horse-dung, and afterwards exposed a month to the sun to dry, at the end of which the camphor is found in form of the crust of a white loaf. This is also called juniper-gum, and mastic.

CAMPHOR-TREE. See LAURUS.

CAMPHORATA, in botany. See POLYCNEMUM.

CAMPION, in botany. See LYCHNIS.

CAMPOIDES, in botany. See SCORPIURUS.

CAMPREDON, a town of Catalonia, in Spain, about fifty miles north of Barcelona: E. long. 2°, and N. lat. 42° 20′.

CAMPUS MAII, in ancient customs, an anniversary assembly of our ancestors held on May-day, when they confederated together for defence of the kingdom against all its enemies.

CAMPUS MARTIUS, among the Romans, a field, by the side of the Tiber, where the youth exercised themselves in warlike exercises. It was so called, on account of a temple that stood on it, consecrated to the god Mars. The consuls Brutus and Collatinus made it the place for holding the comitia or assemblies of the people, and in after-times it was adorned with a great quantity of fine statues.

CAMUS, a person with a low flat nose, hollowed in the middle.

The Tartars are great admirers of camus beauties. Rubruquis observes, that the wife of the great Jenghis Kan, a celebrated beauty, had only two holes for a nose.

CAN, in the sea-language, as can-pump, a vessel, wherewith seamen pour water into the pump to make it go.

CAN-BUOY, a larger size of buoy, used to discover dangerous

gerous rocks and ſhelves, by being placed over them.

CAN-HOOK. See HOOK.

CANADA, or NEW FRANCE, an extenſive tract of North America, bounded by New Britain and the Britiſh colonies on Hudſon's bay, on the north; by the river of St Lawrence, the Iroquois, or five Indian nations, the Huron and Illonois lakes, on the eaſt and ſouth; and by unknown lands, on the weſt. Its chief town is Quebec.

CANAL *of communication*, an artificial cut in the ground, ſupplied with water from rivers, ſprings, *&c.* in order to make a navigable communication betwixt one place and another.

The particular operations neceſſary for making artificial navigations depend upon a number of circumſtances. The ſituation of the ground; the vicinity or connection with rivers; the eaſe or difficulty with which a proper quantity of water can be obtained; theſe and many other circumſtances neceſſarily produce great variety in the ſtructure of artificial navigations, and augment or diminiſh the labour and expence of executing them. When the ground is naturally level, and unconnnected with rivers, the execution is eaſy, and the navigation is not liable to be diſturbed by floods; but, when the ground riſes and falls, and cannot be reduced to a level, artificial methods of raiſing and lowering veſſels muſt be employed; which likewiſe vary according to circumſtances.

A kind of temporary ſluices are ſometimes employed for raiſing boats over falls or ſhoals in rivers by a very ſimple operation. Two poſts or pillars of maſonwork, with grooves, are fixed, one on each bank of the river, at ſome diſtance below the ſhoal. The boat having paſſed theſe poſts, planks are let down acroſs the river by pullies into the grooves, by which the water is dammed up to a proper height for allowing the boat to paſs up the river over the ſhoal.

The Dutch and Fleemings at this day, ſometimes when obſtructed by caſcades, form an inclined plane or rolling-bridge upon dry land, alongſt which their veſſels are drawn from the river below the caſcade into the river above it. This, it is ſaid, was the only method employed by the ancients, and is ſtill uſed by the Chineſe, who are ſaid to be entirely ignorant of the nature and utility of locks. Theſe rolling-bridges conſiſt of a number of cylindrical rollers which turn eaſily on pivots, and a mill is commonly built near by, ſo that the ſame machinery may ſerve the double purpoſe of working the mill and drawing up veſſels.

A LOCK is a baſon placed lengthwiſe in a river or canal, lined with walls of maſonry on each ſide, and terminated by two gates, placed where there is a caſcade or natural fall of the country; and ſo conſtructed, that the baſon being filled with water by an upper ſluice to the level of the waters above, a veſſel may aſcend through the upper gate; or the water in the lock being reduced to the level of the water at the bottom of the caſcade, the veſſel may deſcend through the lower gate; for when the waters are brought to a level on either ſide, the gate on that ſide may be eaſily opened. But as the lower gate is ſtrained in proportion to the depth of water it ſupports, when the perpendicular height of the water exceeds 12 or 13 feet, more locks than one become neceſſary. Thus, if the fall be 17 feet, two locks are required, each having 8½ feet fall; and if the fall be 26 feet, three locks are neceſſary, each having 8 feet 8 inches fall. The ſide-walls of a lock ought to be very ſtrong. Where the natural foundation is bad, they ſhould be founded on piles and platforms of wood: They ſhould likewiſe ſlop outwards, in order to reſiſt the preſſure of the earth from behind.

Plate LX. fig. 1. A perſpective view of part of a canal: the veſſel L, within the lock A C.—Fig. 2. Section of an open lock: the veſſel L about to enter.—Fig. 3. Section of a lock full of water: the veſſel L raiſed to a level with the water in the ſuperior canal.—Fig. 4. Ground ſection of a lock. L, a veſſel in the inferior canal. C, the under gate. A, the upper gate. G H, a ſubterraneous paſſage for letting water from the ſuperior canal run into the lock. K F, a ſubterraneous paſſage for water from the lock, to the inferior canal.

X and Y (fig. 1.) are the two flood-gates, each of which conſiſts of two leaves, reſting upon one another, ſo as to form an obtuſe angle, in order the better to reſiſt the preſſure of the water. The firſt (X) prevents the water of the ſuperior canal from falling into the lock; and the ſecond (Y) dams up and ſuſtains the water in the lock. Theſe flood-gates ought to be very ſtrong, and to turn freely upon their hinges. In order to make them open and ſhut with eaſe, each leaf is furniſhed with a long lever A *b*, A *b*; C *b*, C *b*. They ſhould be made very tight and cloſe, that as little water as poſſible may be loſt.

By the ſubterraneous paſſage G H (fig. 2, 3, & 4.) which deſcends obliquely, by opening the ſluice G, the water is let down from the ſuperior canal D, into the lock, where it is ſtopt and retained by the gate C when ſhut, till the water in the lock comes to be on a level with the water in the ſuperior canal D; as repreſented, fig. 3. When, on the other hand, the water contained by the lock is to be let out, the paſſage G H muſt be ſhut by letting down the ſluice G, the gate A muſt be alſo ſhut, and the paſſage K F opened by raiſing the ſluice K: A free paſſage being thus given to the water, it deſcends through K F, into the inferior canal, until the water in the lock is on a level with the water in the inferior canal B; as repreſented, fig. 2.

Now, let it be required to raiſe the veſſel L (fig. 2.) from the inferior canal B, to the ſuperior one D; if the lock happens to be full of water, the ſluice G muſt be ſhut, and alſo the gate A, and the ſluice K opened, ſo that the water in the lock may run out till it is on a level with the water in the inferior canal B. When the water in the lock comes to be on a level with the water at B, the leaves of the gate C are opened by the levers C *b*, which is eaſily performed, the water on each ſide of the gate being in equilibrio; the veſſel then ſails into the lock. After this the gate C, and the ſluice

Fig. 1.

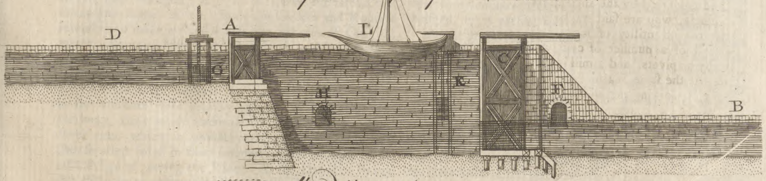

Fig. 4 plan of a Lock

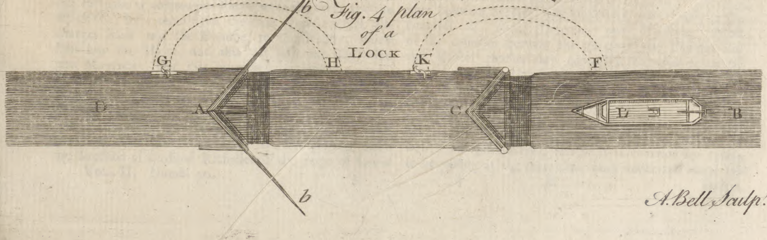

A. Bell Sculp^t.

fluice K are fhut, and the fluice G opened, in order to fill the lock, till the water in the lock, and confequently the veffel, be upon a level with the water in the fuperior canal D; as is reprefented in fig. 3. The gate A is then opened, and the veffel paffes into the canal D.

Again, let it be required to make a veffel defcend from the canal D, into the inferior canal B. If the lock is empty, as in fig. 2. the gate C and fluice K muft be fhut, and the upper fluice G opened, fo that the water in the lock may rife to a level with the water in the upper canal D. Then open the gate A, and let the veffel pafs through into the lock. Shut the gate A and the fluice G: then open the fluice K, till the water in the lock be on a level with the water in the inferior canal; then the gate C is opened, and the veffel paffes along into the canal B, as was required.

It is almoft needlefs to fpend time in enumerating the many advantages which neceffarily refult from artificial navigations. Their utility is now fo apparent, that moft nations in Europe give the higheft encouragement to undertakings of this kind where-ever they are practicable. The advantages of navigable canals did not efcape the obfervation of the ancients. From the moft early accounts of fociety we read of attempts to cut through large ifthmufes, in order to make a communication by water, either betwixt different nations, or diftant parts of the fame nation, where land-carriage was long and expenfive. Herodotus relates, that the Cnidians, a people of Caria in Afia Minor, defigned to cut the Ifthmus which joins that Peninfula to the continent; but were fuperftitious enough to give up the undertaking, becaufe they were interdicted by an oracle. Several Kings of Egypt attempted to join the Red-fea to the Mediterranean. Cleopatra was exceedingly fond of this project. Soliman II. emperor of the Turks, employed 50,000 men in this great work. This canal was compleated under the caliphate of Omar, but was afterwards allowed to fall into difrepair; fo that it is now difficult to difcover any traces of it. Both the Greeks and Romans intended to make a canal acrofs the Ifthmus of Corinth, which joins the Morea and Achaia, in order to make a navigable paffage by the Ionian fea into the Archipelago. Demetrius, Julius Cæfar, Caligula, and Nero, made feveral unfuccefsful efforts to open this paffage. But, as the ancients were intirely ignorant of the ufe of water-locks, their whole attention was employed in making level cuts, which is probably the principal reafon why they fo often failed in their attempts. Charlemagne formed a defign of joining the Rhine and the Danube, in order to make a communication between the ocean and the Black-fea, by a canal from the river Almutz which difcharges itfelf into the Danube, to the Reditz, which falls into the Maine, and this laft falls into the Rhine near Mayence: For this purpofe he employed a prodigious number of workmen; but he met with fo many obftacles from different quarters, that he was obliged to give up the attempt.

The French at prefent have many fine canals: That of Briare was begun under Henry IV. and finifhed under the direction of cardinal Richelieu in the reign of Lewis XIII. This canal makes a communication betwixt the Loire and the Seine by the river Loing. It extends eleven French great leagues from Briare to Montargis. It enters the Loire a little above Briare, and terminates in the Loing at Cepoi. There are forty-two locks on this canal.

The canal of Orleans, for making another communication between the Seine and the Loire, was begun in 1675, and finifhed by Philip of Orleans, regent of France, during the minority of Lewis XV. and is furnifhed with twenty locks. It goes by the name of the canal of Orleans; but it begins at the village of Combleux, which is a fmall French league from the town of Orleans.

But the greateft and moft ufeful work of this kind is the junction of the ocean with the Mediterranean by the canal of Languedoc. It was propofed in the reigns of Francis I. Henry IV. and was undertaken and finifhed under Lewis XIV. It begins with a large refervoir 4000 paces in circumference, and 24 feet deep, which receives many fprings from the mountain Noire. This canal is about 64 leagues in length, is fupplied by a number of rivulets, and is furnifhed with 104 locks, of about eight feet rife each. In fome places it paffes over bridges of vaft height; and in others it cuts through folid rocks for 1000 paces. At one end it joins the river Garonne near Tholoufe, and terminates at the other in the lake Tau, which extends to the port of Cette. It was planned by Francis Riquet in the 1666, and finifhed before his death, which happened in the 1680.

In the Dutch, Auftrian, and French Netherlands, there is a very great number of canals; that from Bruges to Oftend carries veffels of 200 tons.

The Chinefe have alfo a great number of canals; that which runs from Canton to Pekin, extends about 825 miles in length, and was execute about 800 years ago.

It would be an endlefs tafk to defcribe the numberlefs canals in Holland, Ruffia, Germany, *&c.* We fhall therefore confine ourfelves to thofe that are either already finifhed, or at prefent executing in our own country.

As the promoting of commerce is the principal intention of making canals, it is natural to expect that their frequency in any nation fhould bear fome proportion to the trade carried on in it, providing the fituation of the country will admit of them. The prefent ftate of England and Scotland confirms this obfervation. Though the Romans made a canal between the Nyne, a little below Peterborough, and the Witham, three miles below Lincoln, which is now almoft entirely filled up, yet it is not long fince canals were revived in England. They are now however become very numerous, particularly in the counties of York, Lincoln, and Chefhire. Moft of the counties betwixt the mouth of the Thames and the Briftol channel are connected together either by natural or artificial navigations; thofe upon the Thames and Ifis reaching within about twenty miles of thofe upon the Severn. The duke of Bridgewater's canal in Chefhire runs twenty-feven miles on a perfect level; but at Barton it is carried by a very high aqueduct bridge over the Irwell, a navigable river; fo that it is common for veffels to be paffing at the fame time both under and above the bridge.

bridge. It is likewise cut some miles into the hills, where the Duke's coal mines are wrought.

Though a navigable communication between the rivers Forth and Clyde in Scotland had been long talked of, it was never considered with a view to execution till the year 1761, when the ground was surveyed by Mr Smeaton, at the desire of the trustees for fisheries and manufactures in Scotland. From Mr Smeaton's survey and report, the practicability of this canal was fully demonstrated. But, after the scheme became an object of general attention, it was found that a canal of larger dimensions than the one originally proposed would be productive of still greater advantages to the nation. Mr Smeaton was therefore directed to make a second survey, and to report to the intended proprietors an estimate of the expence of making a canal 24 feet broad at bottom, 54 at top, containing seven feet deep of water, and extending from the Forth to the Clyde, a distance of about 31 miles, with a collateral branch to the town of Glasgow, which is about six miles, and another from Bainsford to the river Carron, below Carron-works, making in all about 37 miles. This report was approved of, an act of parliament was obtained, and the canal is now cutting upon this very plan. It begins at the Holemerrie in the mouth of the Carron, and terminates at Dalmuir-burn-foot on the river Clyde, about seven miles below Glasgow. Above seven miles are already cut, from the Holemerrie westward; a number of hands are likewise employed at the point of partition in Dollater-bog, and the whole is expected to be finished in five years. At the point of partition, which is 168 feet above the level of the sea at low water, a very large reservoir is to be made for supplying the canal; and the vessels are to be raised and lowered by means of 41 locks. Where the course of the canal is intersected by burns or rivers, it is to be carried over them by aqueduct-bridges; three of these bridges will be large, and require considerable labour and expence, *viz.* one over the Grange-burn, one over Bony-mill-burn, and a third over the Kelvin in the Glasgow branch. The expence of executing the whole is computed to be about 150,000 l.

Sea-vessels, about 20 feet wide and 60 feet long, and carrying 70 or 80 tons, may pass along by this canal from the one frith to the other. But it will admit a free passage to vessels of 140 tons, provided they be built in the manner of the flat vessels used by the Dutch. The toll-duty, allowed by the act of parliament, is not to exceed 2 d. a ton *per* mile. Privileged goods, such as lime and lime-stone, are to pay only one third of the usual toll-duty; stones, gravel, and other materials for making or repairing roads, likewise dung, soil, marle, and all sorts of manure, are exempted from paying any toll-duty, provided they do not pass any lock but when the water shall flow over the place made for discharging the overplus-water in the canal.

We must not conclude this article without observing, that in Ireland also the utility of artificial navigations has not been unattended to. Several canals are there making; in particular, one from Loch-Neach to Newry, about 20 miles; and another from the river Shannon to Dublin, about 70 miles.

CANAL, in anatomy, a duct or passage through which any of the juices flow.

CANARIES, islands, to the number of seven, situated in the Atlantic ocean, between 12° 21′ W. long. and between 27° and 29° N. lat. the most easterly of them lying about 150 miles from Cape Non, on the coast of Biledulgerid, in Africa.

CANARY, properly so called, is a considerable island, about 150 miles in circumference; the chief town of which is Palma, from whence comes the excellent palm-sack, and other rich wines.

It lies in 16° W. long. and between 27° and 28° N. lat.

CANARY-*bird*. See FRINGILLA.

CANCALE, a small town of France, near St Malo's, where ships may ride in eight fathoms water, with a sandy bottom.

CANCELIER, in falconry, is when a light-brown hawk, in her stooping, turns two or three times upon the wing, to recover herself, before she seizes.

CANCELLI, a term used to denote lattice-windows, or those made of cross-bars, disposed lattice-wise; it is also used for rails or ballusters, inclosing the communion-table, a court of justice, and the like, and for the net-work in the inside of hollow bones.

CANCER, or CRAB, in zoology, a genus of insects belonging to the order of insecta aptera. The generic characters are these: They have eight legs, (seldom ten or six), besides the two large claws which answer the purpose of hands. They have two eyes at a considerable distance from each other, and for the most part supported by a kind of pedunculi or foot-stalks; the eyes are likewise elongated and moveable. They have two clawed palpi; and the tail is jointed. There are no less than 87 species of cancer, distinguished principally by the length of their tails and the margins of their breasts. This genus includes the lobster, shrimp, *&c.*

CANCER, in medicine, a roundish, unequal, hard, and livid tumour, generally seated in the glandulous parts of the body, supposed to be so called, because it appears at length, with turgid veins shooting out from it, so as to resemble, as it is thought, the figure of a crab-fish; or, as others say, because, like that fish, where it has once got, it is scarce possible to drive it away. See MEDICINE, and SURGERY.

CANCER, in astronomy, one of the twelve signs of the zodiac, represented on the globe in the form of a crab, and thus marked (♋) in books.

Tropic of CANCER, in astronomy, a lesser circle of the sphere parallel to the equator, and passing through the beginning of the sign cancer.

CANCHERIZANTE, or CANCHERIZATO, in the Italian music, a term signifying a piece of music that begins at the end, being the retrograde motion from the end of a song, *&c.* to the beginning.

CANDAROR, the capital of a territory of the same name, subject to Persia: E. long. 67°, and N. lat. 33°.

CANDIA, the modern name of Crete, an island situated in-

in the Mediterranean fea, between 22° and 27° E. long. and between 35° and 36° N. lat.

There is no river of any confequence in the whole ifland, which is watered by a multitude of rivulets; whereof Lethe is one. Here too is mount Ida, fo much celebrated in the writings of the ancients.

CANDIA, or MUTIUM, is the capital of the above ifland, fituated on its northern coaft, in 25° E. long. and 35° 30′ N. lat.

CANDIDATE, a perfon who afpires to fome public office.

In the Roman commonwealth, they were obliged to wear a white gown, during the two years of their foliciting for a place. This garment, according to Plutarch, they wore without any other cloaths, that the people might not fufpect they concealed money for purchafing votes; and alfo, that they might the more eafily fhow to the people, the fcars of thofe wounds they had received in fighting for the defence of the commonwealth.

CANDIDATI MILITES, an order of foldiers, among the Romans, who ferved as the emperor's body-guards, to defend him in battle. They were the talleft and ftrongeft of the whole troops, and moft proper to infpire terror. They were called *candidati*, becaufe cloathed in white, either that they might be more confpicuous, or becaufe they were confidered in the way of preferment.

CANDISH, a province of the hither India, bounded by Chitor and Malva, on the north; by Orixa, on the eaft; by Decan, on the fouth; and by Guzurat, on the weft: It is fubject to the Mogul.

CANDLE, a fmall taper of tallow, wax, or fpermaceti; the wick of which is commonly of feveral threads of cotton, fpun and twifted together.

A tallow-candle, to be good, muft be half fheeps, and half bullocks tallow; for hogs tallow makes the candle gutter, and always gives an offenfive fmell, with a thick black fmoke. The wick ought to be pure, fufficiently dry, and properly twifted; otherwife the candle will emit an unconftant vibratory flame, which is both prejudicial to the eyes, and infufficient for the diftinct illumination of objects.

There are two forts of tallow-candles; the one dipped, the other moulded: The former are the common candles; the others are the invention of the fieur le Brege at Paris.

As to the method of making candles, in general; After the tallow has been weighed, and mixed in the due proportions, it is cut into very fmall pieces, that it may melt the fooner; for the tallow in lumps, as it comes from the butchers, would be in danger of burning or turning black, if it were left too long over the fire. Being perfectly melted and fkimmed, they pour a certain quantity of water into it, proportionable to the quantity of tallow. This ferves to precipitate, to the bottom of the veffel, the impurities of the tallow, which may have efcaped the fkimmer. No water, however, muft be thrown into the tallow defigned for the three firft dips; becaufe the wick, being ftill quite dry, would imbibe the water, which makes the candles crackle in burning, and renders them of bad ufe. The tallow, thus melted, is poured into a tub, through a coarfe fieve of horfe-hair, to purify it ftill more, and may be ufed after having ftood three hours. It will continue fit for ufe twenty-four hours in fummer, and fifteen in winter.

The wicks are made of fpun cotton, which the tallow-chandlers buy in fkains, and which they wind up into bottoms or clues. Whence they are cut out, with an inftrument contrived on purpofe, into pieces of the length of the candle required; then put on the fticks or broaches, or elfe placed in the moulds, as the candles are intended to be either dipped or moulded. Wax-candles are made of a cotton or flaxen wick, flightly twifted, and covered with white or yellow wax. Of thefe, there are feveral kinds; fome of a conical figure, ufed to illumine churches, and in proceffions, funeral ceremonies, *&c.* See TAPER.

Others of a cylindrical form, ufed on ordinary occafions.

The firft are either made with a ladle or the hand.

To make wax candles with the ladle.

The wicks being prepared, a dozen of them are tied by the neck, at equal diftances, round an iron circle, fufpended directly over a large bafon of copper tinned, and full of melted wax: A large ladle full of this wax is poured gently on the tops of the wicks one after another, and this operation continued till the candle arrive at its deftined bignefs; with this precaution, that the three firft ladles be poured on at the top of the wick, the fourth at the height of $\frac{3}{4}$, the fifth at $\frac{1}{2}$, and the fixth at $\frac{1}{4}$, in order to give the candle its pyradimal form. Then the candles are taken down, kept warm, and rolled and fmoothed upon a walnut-tree table, with a long fquare inftrument of box, fmooth at the bottom.

As to the manner of making wax-candles by the hand, they begin to foften the wax, by working it feveral times in hot water, contained in a narrow, but deep caldron. A piece of the wax is then taken out, and difpofed by little and little, around the wick, which is hung on a hook in the wall, by the extremity oppofite to the neck; fo that they begin with the big end, diminifhing ftill as they defcend towards the neck. In other refpects, the method is nearly the fame as in the former cafe. However, it muft be obferved, that in the former cafe, water is always ufed to moiften the feveral inftruments, to prevent the wax from fticking; and in the latter, oil of olives, or lard, for the hands, *&c.* The cylindrical wax-candles are either made, as the former, with a ladle, or drawn. Wax-candles drawn, are fo called, becaufe actually drawn in the manner of wire, by means of two large rollers of wood, turned by a handle, which turning backwards and forwards feveral times, pafs the wick through melted wax contained in a brafs bafon, and at the fame time through the holes of an inftrument like that ufed for drawing wire faftened at one fide of the bafon.

Makers of candles are not to ufe melting-houfes, without due entry thereof at the excife-office, on pain

of

of 100l.; and to give notice of making candles to the excise-officer for the duties, and of the number, &c. or shall forfeit 50l. Removing the candles before weighed by the officer, or mixing them with others, is likewise liable to penalties.

CANDLE is also a term in medicine, and is reckoned among the instruments of surgery. Thus the candela fumalis, or the candela pro suffitu odorata, is a mass of an oblong form, consisting of odoriferous powders, mixed up with a third, or more, of the charcoal of willow or lime-tree, and reduced to a proper consistence with a mucilage of gum-tragacanth, ladanum, or turpentine. It is intended to excite a grateful smell without any flame, to correct the air, to fortify the brain, and to excite the spirits.

Medicated CANDLE, or BOUGIE, in surgery, a small stick of wax in form of a candle, which surgeons introduce into the uretha, either to dilate it and keep it open, or to consume carnosities. There are two sorts of these candles, the one simple, and the other compound. The simple are made of wax, of cat-gut, or even of lead; and the intention of them is to keep the canal of the urethra properly distended. Their thickness, therefore, should be proportioned to the diameter of that canal. The compound bougies are loaded with some medicine capable of producing a suppuration, or of destroying carnosities and excrescences in the urethra. See SURGERY.

CANDLE. Sale or auction by inch of candle, is when a small piece of candle being lighted, the bystanders are allowed to bid for the merchandise that is selling; but the moment the candle is out, the commodity is adjudged to the last bidder.

There is also an excommunication by inch of candle; when the sinner is allowed to come to repentance while a lighted candle continues burning; but after it is consumed, he remains excommunicated to all intents and purposes.

CANDLE-BERRY-TREE, in botany. See MYRICA.

CANDLEMAS, a feast of the church held on the second day of February, in honour of the purification of the Virgin Mary. It is borrowed from the practice of the ancient Christians, who on that day used abundance of lights both in their churches and processions, in memory, as is supposed, of our Saviour's being, on that day, declared by Simeon, "to be a light to lighten the Gentiles." In imitation of this custom, the Roman catholics, on this day, consecrate all the tapers and candles which they use in their churches during the whole year. At Rome, the pope performs that ceremony himself, and distributes wax-candles to the cardinals and others, who carry them in procession through the great hall of the pope's palace. This ceremony was prohibited in England, by an order of council in 1548.

CANDLESTICK, an instrument to hold a candle, made in different forms, and of all sorts of matter.

The golden candlestick was one of the sacred utensils made by Moses to be placed in the Jewish tabernacle. It was made of hammered gold, a talent in weight. It consisted of seven branches, supported by a base or foot. These branches were adorned at equal distances with six flowers like lilies, and with as many bowls and knobs placed alternately. Upon the stock and six branches of the candlestick, were the golden lamps, which were immoveable, wherein were put oil and cotton.

These seven lamps were lighted every evening, and extinguished every morning. The lamps had their tongs or snuffers to draw the cotton in or out, and dishes underneath them to receive the sparks and droppings of the oil. This candlestick was placed in the antichamber of the sanctuary on the south-side, and served to illuminate the altar of perfume, and the table of the shew-bread. When Solomon had built the temple of the Lord, he placed in it ten golden candlesticks, of the same form as that described by Moses, five on the north, and five on the south-side of the holy. But after the Babylonish captivity, the golden candlestick was again placed in the temple, as it had been before in the tabernacle by Moses. This sacred utensil, upon the destruction of the temple by the Romans, was lodged in the temple of Peace, built by Vespasian; and the represensation of it is still to be seen on the triumphal arch at the foot of mount Palatine, on which Vespasian's triumph is delineated.

Water-CANDLESTICK, a kind of fountain, the spout of which is raised upon a pedestal in form of a large balustrade, which carries a small bason like a table or stand, from which the water falls into a larger bason, level with the alleys in a garden.

CANDY, in geography, the capital of the island of Ceylon, situated in the middle of the island: E. long. 79°, N. lat. 8°.

CANDY, or *Sugar*-CANDY, a preparation of sugar, made by melting and crystalizing it six or seven times over, to render it hard and transparent. It is of three kinds, white, yellow, and red. The white comes from the loaf-sugar, the yellow from the cassonado, and the red from the muscovado.

CANDYING, in pharmacy, the act of preserving simples in substance, by boiling them in sugar.

The performance of this originally belonged to the apothecaries, but is now become a part of the business of a confectioner.

CANE, in botany. See ARUNDO.

CANE denotes also a walking-stick. It is customary to adorn it with a head of gold, silver, agate, &c. Some are without knots, and very smooth and even; others are full of knots, about two inches distant from each other. These last have very little elasticity, and will not bend so well as the others.

Canes of Bengal, are the most beautiful which the Europeans bring into Europe. Some of them are so fine, that people work them into vessels or bowls, which being varnished over in the inside with black or yellow lacca, will hold liquors as well as glass or china-ware does, and the Indians use them for that purpose.

CANE is also the name of a long measure, which differs according to the several countries where it is used.

At Naples, the cane is equal to 7 feet $3\frac{1}{2}$ inches English

English meafure: The cane of Tholoufe and the upper Languedoc is equal to the varre of Arragon, and contains 5 feet $8\frac{2}{7}$ inches; at Montpelier, Provence, Dauphine, and the lower Languedoc, to 6 Englifh feet $5\frac{1}{2}$ inches.

CANEA, a fea-port town on the north fide of Candia, efteemed the fecond in the ifland. It is a pretty good harbour, but the fortifications are out of repair: E. long. 24°, N. lat. 35° 36′.

CANEPHORÆ, in Grecian antiquity, virgins who, when they became marriageable, prefented certain bafkets full of little curiofities to Diana, in order to get leave to depart out of her train, and change their ftate of life.

CANEPHORIA, in Grecian antiquity, a ceremony which made part of a feaft celebrated by the Athenian virgins, on the eve of their marriage-day.

At Athens, the canephoria confifted in this; that the maid, conducted by her father and mother, went to the temple of Minerva, carrying with her a bafket full of prefents, to engage the goddefs to make the marriage-ftate happy; or, as the fcholiaft of Theocritus has it, the bafket was intended as a kind of honourable amends made to that goddefs, the protectrix of virginity, for abandoning her party; or a ceremony to appeafe her wrath. Suidas calls it a feftival in honour of Diana.

CANEPHORIA is alfo the name of a feftival of Bacchus, celebrated particularly by the Athenians, on which the young maids carried golden bafkets full of fruit, which bafkets were covered, to conceal the myftery from the uninitiated.

CANETO, a fortified town of the duchy of Mantua, fituated on the Oglio, about twelve miles fouth-weft of Mantua: E. long. 10° 50′, N. lat. 45°.

CANG, a gulf or fea, lying between China and Tartary, at the eaft end of the long wall.

CANICULA, in ichthyology, the trivial name of a fpecies of fqualus. See SQUALUS.

CANICULA, or CANICULUS, in aftronomy. See ASTRONOMY, *Of fixed ftars.*

It is alfo a name given to one of the ftars of the conftellation canis major, called the dog-ftar, and by the Greeks, firius.

CANICULAR *days*, commonly called dog-days, a certain number of days preceding and enfuing the heliacal raifing of canicula, or the dog-ftar, in the morning. The Ethiopians and Egyptians began their year at the rifing of the dog-ftar, reckoning to its rife again the next year, which is called the annus canarius. The Romans fuppofed it to be the caufe of the fultry weather ufually felt in the dog-days; and therefore facrificed a brown dog every year at its rifing, to appeafe its wrath.

The dog-days begin towards the end of July, and end the beginning of September.

CANINE, whatever partakes of, or has any relation with the nature of a dog. Thus,

CANINE *teeth*, are two fharp-edged teeth in each jaw; one on each fide, placed between the incifores and molares.

CANIS, or DOG, in zoology, a genus of quadrupeds, belonging to the order of feræ. The characters of the dog are thefe: He has fix fore-teeth in the upper jaw, thofe in the fides being longer than the intermediate ones, which are lobated; in the under jaw there are likewife fix fore-teeth, thofe on the fides being lobated. He has fix grinders in the upper, and feven in the lower jaw. The teeth called dog-teeth are four, one on each fide, both in the lower and upper jaw; they are fharp-pointed, bent a little inward, and ftand at a diftance from any of the reft.

There are nine fpecies of this genus, *viz.* 1. The familiaris, or domeftic dog, is diftinguifhed from the other fpecies, by having his tail bent to the left fide; which mark is fo fingular, that perhaps the tail of no other quadruped is bent in this manner. Of this fpecies there are a great number of varieties. Linnæus enumerates eleven, and Bouffon gives figures of no lefs than twenty-feven, *viz.* the moloffus, or maftiff, which is about the fize of a wolf, with the fides of the lips hanging down, and a full robuft body. The large Danifh dog, differs only from the former in being fuller in the body, and generally of a larger fize. The grey-hound is likewife the fame with the maftiff; but its make is more flender and delicate. Indeed the difference betwixt thefe three dogs, although perfectly diftinguifhable at firft fight, is not greater than that betwixt a Dutchman, a Frenchman, and an Italian. The fhepherd's dog, the wolf-dog, and what is commonly called the Siberian dog, to which may be joined the Lapland dog, the Canada dog, and, in general, all thofe which have ftrait ears and a pointed fnout, are all one kind, differing only in thicknefs, the roughnefs or fmoothnefs of their fkin, the length of their legs, and tails. The hound, or beagle, the terrier, the braque, or fhort-tailed fetting-dog, and the fpaniel, may be confidered as the fame kind: they have the fame form and the fame inftincts; and differ only in the length of their legs, and fize of their ears, which in each of them are long, foft, and pendulous. The bull-dog, the fmall Danifh dog, the Turkifh dog, and the Iceland dog, may likewife be confidered as the fame kind, all the varieties in their appearance taking their rife merely from climate. For inftance, the Turkifh dog, which has no hair, is nothing elfe but the fmall Danifh dog tranfported to a warm climate, which makes the hair fall off. A dog of any kind lofes its hair in very warm climates. But this is not the only change which arifes from difference of climate. In fome countries, the voice is changed; in others, dogs become altogether filent. In fome climates, they lofe the faculty of barking, and howl like wolves, or yelp like foxes. Warm climates even change their form and inftincts: They turn ill-fhaped, and their ears become ftrait and pointed. It is only in temperate climes that dogs preferve their natural courage, ardour, and fagacity.

In order to give an idea of the different kinds of dogs, in different climates, and of the varieties produced by commixtures, we fhall give an explanation of Bouffon's genealogical tree, See Plate LXI. fig. 1. This tree is conftructed in the form of a geographical chart, in which the fituation of the different climates to which the parti-

cular dogs belong, is obferved as accurately as the nature of the thing will admit.

The fhepherd's dog is the ftump of the tree. This dog, when tranfported to Lapland, or any very cold climate, affumes an ugly appearance, and its legs become fhort. But in Britain, Ruffia, Siberia, *&c.* where the cold is not fo rigorous, and the people are more civilized, he arrives at greater perfection, both in form and fagacity. The fame fhepherd's dog, when brought up in a country fully civilized, as Britain or France, lofes his favage air, his ftrait ears, his thick long hair, and becomes what is called a bull-dog, a maftiff, a beagle, or hound. Thefe changes, Bouffon attributes to the influence of the climate, the manners of the people, *&c.* The maftiff and the bull-dog have their ears ftill partly ftrait, or half-pendent, and refemble in their manners and fanguine difpofition the dog from which they derive their origin. The beagle or hound preferves lefs of the appearance of its origin than the other two; its ears are long and entirely pendent; the foftnefs, the tractability, the timidity of this dog, Bouffon confiders as fo many proofs of its great degeneracy, or rather of that perfection which it acquires by culture, and living among a civilized people.

The hound, the fmall fpotted fetting-dog, and the terrier, are all of the fame family; for all the three kinds are often produced at the fame litter, although the female hound had been covered only by one of thefe kinds.

When the hound is tranfported to Spain, or Barbary, where almoft every animal has fine, long, downy hair, it is changed into a water hound, or fpaniel. And the fmall and large fpaniel, which differ only in the tail, when carried to Britain, are changed from a white to a black colour, and become what is called the large and fmall fhagged dogs.

The maftiff, when carried to the north, is changed into the large Danifh dog; and when tranfported to the fouth, it becomes a grey-hound. The large grey-hounds come from the Levant; thofe of a leffer fize come from Italy; and the Italian grey-hounds, when brought to Britain, become what the French call *levrons*, that is, grey-hounds of the leaft fize.

The great Danifh dog, when carried to Ireland, the Ukrain, Tartary, *&c.* is changed into the Irifh dog, which is the largeft of all dogs.

The bull-dog, when carried from Britain to Denmark, becomes the fmall Danifh dog; and this fmall Danifh dog, when tranfported into a warm climate, lofes its hair, and is changed into the Turkifh dog.

All thefe races or families, with their varieties, are produced by the influence of climate, food, and education: The other kinds marked in the tree are not pure or diftinct families, but are produced by the commixture of the other families. Thefe mungrel dogs, with the particular parents which produce them, are marked out in the tree by dotted lines. For example,

The grey-hound and maftiff produce the mungrel grey-hound, which is likewife called the grey-hound with wolf's hair. The large Danifh dog and the large fpaniel produce the Calabrian dog; which is a beautiful dog, with long bufhy hair, and of a larger fize than the maftiff. The fpaniel and the fmall Danifh dog produce the lion-dog, which is a very rare kind. It is needlefs to give more examples, as they can eafily be traced from the dotted lines in the tree.

Having thus traced the varieties of the dog, and the probable fources of thefe varieties, we fhall now give an account of his nature and inftincts.

From the ftructure of the teeth, it might be concluded *à priori* that the dog is a carnivorous animal. He does not however eat indifcriminately every kind of animal fubftance. There are fome birds, as the colymbus arcticus, which the water-dog will lay hold off with keennefs, but will not bring out of the water, becaufe its fmell is exceedingly offenfive to him. He will not eat the bones of a goofe, crow, or hawk: But he devours even the purtrid flefh of moft other animals. He is poffeffed of fuch ftrong digeftive powers, as to draw nourifhment from the hardeft bones. When flefh cannot be procured, he will eat fifh, fruits, fucculent herbs, and bread of all kinds. When oppreffed with ficknefs, to which he is very fubject, efpecially in the beginning of fummer, in order to procure a puke, he eats the leaves of the quicken grafs, the bearded wheat-grafs, or the rough cock's-foot-grafs, which gives him immediate relief. When he fteals a piece of flefh, as confcious of the immorality of the action, he runs off with his tail hanging and bent in betwixt his feet.

His drink is water, which he takes in fmall quantities at a time, by licking with his tongue. He is in fome meafure obliged to lick in this manner, otherwife his nofe would be immerfed in the water.

His excrements are generally hard fcybals, which, efpecially after eating bones, are white, and go by the name of *album græcum* among phyficians. This album græcum was for a long time in great repute as a feptic; but it is now entirely difregarded. He does not throw out his excrements promifcuoufly upon every thing that happens to be in the way, but upon ftones, trunks of trees, or barren places. This is a wife inftitution of nature; for the excrements of a dog deftroy almoft every vegetable or animal fubftance. They are of fuch a putrid nature, that if a man's fhoe touches them when recently expelled, that particular part will rot in a few days. He obferves the fame method in making his urine, which he throws out at a fide. It is remarkable, that a dog will not pafs a ftone or a wall againft which any other dog has piffed, without following his example, although a hundred fhould occur in a few minutes, in fo much, that it is aftonifhing how fuch a quantity can be fecreted in fo fhort a time.

The dog is an animal not only of quick motion, but remarkable for travelling very long journeys. He can eafily keep up with his mafter, either on foot or horfeback, for a whole day. When fatigued, he does not fweat, but lolls out his tongue. Every kind of dog can fwim; but the water-dog excells in that article.

The dog runs round when about to lie down, in order to difcover the moft proper fituation. He lies generally on his breaft, with his head turned to one fide, and fometimes with his head above his two fore-feet. He fleeps little, and even that does not feem to be very quiet; for he often

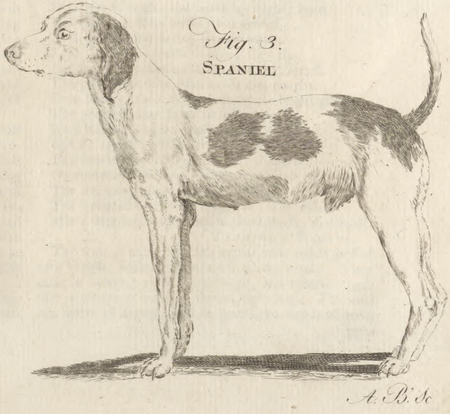
SPANIEL



A. B. Sc

often ſtarts, and ſeems to hear with more acuteneſs in ſleep than when awake. They have a tremulous motion in ſleep, frequently move their legs, and bark, which is an indication of dreaming.

Dogs are poſſeſſed of the ſenſation of ſmelling in a high degree. They can trace their maſter by the ſmell of his feet in a church, or in the ſtreets of a populous city. This ſenſation is not equally ſtrong in every kind. The hound can trace game, or his maſter's ſteps, twenty-four hours afterwards. He barks more furiouſly the nearer he approaches the fowls, unleſs he be beat and trained to ſilence.

With regard to the propagation of dogs; the females admit the males before they are twelve months old. They remain in ſeaſon ten, twelve, or even fifteen days, during which time they will admit a variety of males. They come in ſeaſon generally twice in the year, and more frequently in the cold than in the hot months. The male diſcovers the condition of the female by the ſmell; but ſhe ſeldom admits him the firſt ſix or ſeven days. One coitus will make her conceive a great number of young; but, when not reſtrained, ſhe will admit ſeveral dogs every day: ſhe ſeems to have no choice or predilection, except in favour of large dogs: From this circumſtance, it ſometimes happens, that a ſmall female, who has admitted a maſtiff, periſhes in bringing forth her young. During the time of copulation, theſe animals cannot ſeparate themſelves, but remain united ſo long as the erection ſubſiſts. This is owing to the ſtructure of the parts. The dog has not only a bone in his penis, but in the middle of the corpus cavernoſum there is a large hollow, which is blown up in the time of erection to a conſiderable bulk. The female, on the other hand, has a larger clitoris then perhaps any other animal; beſides a large firm protuberance riſes in the time of copulation, and remains perhaps longer than that of the male, and prevents him from retiring till it ſubſides: Accordingly after the act of copulation is over, the male turns about in order to reſt himſelf on his legs, and remains in that poſition till theſe parts turn flaccid. The female goes with young about nine weeks. They generally bring forth from ſix to twelve puppies. Thoſe of a ſmall ſize bring forth five, four, and ſometimes but two. They continue to copulate and bring forth during life, which laſts generally about fourteen or fifteen years. The whelps are commonly blind, and cannot open their eyes till the tenth or twelfth day. In the fourth month, they loſe ſome of their teeth, which are ſoon ſucceeded by others.

The dog has ſuch a ſtrong reſemblance to the wolf and the fox, that he is commonly ſuppoſed to be the production of one or other of theſe animals tamed and civilized. Bouffon informs us, that he kept a young dog and a young wolf together till they were three years of age, without their diſcovering the leaſt inclination to copulate. He made the ſame experiment upon a dog and a fox; but their antipathy was rather increaſed when the female was in ſeaſon. From theſe experiments he concludes, that dogs, wolfs, and foxes, are perfectly diſtinct ſpecies of animals.

With regard to the natural diſpoſition of the dog: In a ſavage ſtate, he is fierce, cruel, and voracious; but, when civilized and accuſtomed to live with men, he is poſſeſſed of every amiable quality. He ſeems to have no other deſire than to pleaſe and protect his maſter. He is gentle, obedient, ſubmiſſive, and faithful. Thoſe diſpoſitions, joined to his almoſt unbounded ſagacity, juſtly claim the eſteem of mankind. Accordingly no animal is ſo much careſſed or reſpected: He is ſo ductile, and ſo much formed to pleaſe, that he aſſumes the very air and temper of the family in which he reſides.

An animal endowed with ſuch uncommon qualities, muſt anſwer many uſeful purpoſes. His fidelity and vigilance are daily employed to protect our perſons, our flocks, or our goods. The acuteneſs of his ſmell gains him employment in hunting; in ſome parts of Siberia, he is trained to draw carriages from one inn to another; and the negroes eat dogs fleſh with great reliſh.

The dog is liable to many diſeaſes, as the ſcab, madneſs, *&c.* and he ſeldom wants the tænia or tape-worm in his guts, eſpecially if he drinks dirty water. See Plate VIII. 62.

2. The ſecond ſpecies of this kind is the lupus or wolf, which is diſtinguiſhed from the dog by having its tail turned inward. The wolf is larger and fiercer than a dog. His eyes ſparkle, and there is a great degree of fury and wildneſs in his looks. He draws up his claws when he walks, to prevent his tread from being heard. His neck is ſhort, but admits of very quick motion to either ſide. His colour is generally blackiſh. Like moſt ferocious animals, he can bear hunger a very long time; but, at laſt, when the appetite for victuals becomes intolerable, he grows perfectly furious, and will attack men, horſes, dogs, and cattle of all kinds; even the graves of the dead are not proof againſt his rapacity. This circumſtance is finely deſcribed, in the following lines.

By wintry famine rous'd,——————
Cruel as death, and hungry as the grave!
Burning for blood! bony, and ghant, and grim!
Aſſembling wolves in raging troops deſcend;
And, pouring o'er the country, bear along,
Keen as the north-wind ſweeps the gloſſy ſnow.
All is their prize. They faſten on the ſteed,
Preſs him to earth, and pierce his mighty heart.
Nor can the bull his awful front defend,
Or ſhake the murthering ſavages away.
Rapacious at the mother's throat they fly,
And tear the ſcreaming infant from her breaſt.
The god-like face of Man avails him nought.
Even beauty, force divine! at whoſe bright glance
The generous lion ſtands in ſoften'd gaze,
Here bleeds, a hapleſs undiſtinguiſh'd prey.
But if, appris'd of the ſevere attack,
The country be ſhut up, lur'd by the ſcent,
On church-yards drear (inhuman to relate!)
The diſappointed prowlers fall, and dig
The ſhrouded body from the grave; o'er which,
Mix'd with foul ſhades, and frighted ghoſts, they howl.

Thomson's Winter.

The wolf is extremely ſuſpicious, and, unleſs preſſed with hunger, ſeldom ventures out of the woods. They make a howling noiſe in the night, and aſſemble together in troops in order to devour their prey. The wolf is a native of Europe, and frequents the woods of many

parts of the continent to this day. This country, a few centuries ago, was much infefted with them. So late as the year 1457, there is an act of parliament obliging all the gentlemen and tenants in the different fhires of Scotland, to rife, properly armed, four times in the year, in order to deftroy the wolves. But they are now fo effectually rooted out, that not one of them has been feen wild, even in the highlands, for a century paft. See Plate LXII. fig. 5.

3. The hyæna, has a ftrait jointed tail, with the hair of its neck erect, fmall naked ears, and four toes on each foot. It is about the fize of a fow, and its head refembles that of a boar. The hairs on the back are about a fpan long, erect, and black at the points, and the eyes are near each other. The hyæna is a native of India and Africa. He digs holes in the earth like a fox, where he retires from danger. He is very fond of human flefh, which he digs out of church-yards in the night. When irritated, he lays hold of a weapon, or any thing that offends, and keeps it faft in his teeth, which makes him an eafy prey to hunters.

4. The vulpes, or fox, has a ftrait tail, white at the point. His body is yellowifh, or rather ftraw-coloured; his ears are fmall and erect; his lips are whitifh, and his fore-feet are black. From the bafe of the tail, a ftrong fcent is emitted, which to fome people is very fragrant, and to others extremely difagreeable. The fox is a native of almoft every quarter of the globe: He digs holes or dens in the earth; and is of fuch a wild and favage difpofition, that it is impoffible fully to tame him. He is efteemed to be the moft crafty and cunning of all beafts of prey. His craftinefs is principally difcovered by the fchemes he falls upon in order to catch lambs, geefe, hens, and all kinds of fmall birds. When the females are in feafon, they make a difagreeable yelping noife in the night. He flies when he hears the explofion of a gun, or fmells gun-powder. He is exceedingly fond of grapes, and does much mifchief in vineyards. Various methods are daily employed to deftroy foxes; they are hunted with dogs; iron-traps are often fet at their holes; and their holes are fometimes fmoked to make them run out, that they may the more readily fall into the fnares, or be killed by dogs or fire-arms. But all the arts that have been employed are infufficient for the purpofe of rooting him out of any country. They have fo many paffages in their dens, and often at a great diftance, that they often make their efcape. When hunted, they never run directly foreward, but make a great many doublings and turnings; and when in danger of being taken, they emit fuch a fmell from their pofteriors, that the hunters can hardly endure it. See Plate LXII. fig. 4.

5. The alopex, or field-fox, is every way the fame with the common fox, except in the point of the tail, which is black.

6. The lagopus, or white fox, with a ftrait tail, and the apex of different colours. The legs are very hairy. It inhabits the mountains of Lapland and Siberia.

7. The aureus, or jackall, is a native of the Eaft Indies. There is no genuine defcription of this animal. They affemble in large troops in the night, in feveral parts of Afia, and make a hideous howling noife. When one calls, he is anfwered by numbers even at great diftances; fo that in a fhort time the whole woods refound with their noife. This noife roufes all the other wild animals, as lions, tygers, *&c.* who take advantage of the general confternation, and devour the weaker animals. This circumftance has probably given rife to the notion of the jackall's being the lion's provider. They hide themfelves in holes during the day, and go in queft of their prey in the night: They fometimes fall upon children, and devour them when no affiftance is near.

8. The Mexicanus, has a fmooth crooked tail. The body is afh-coloured, variegated with yellow fpots. It is a native of Mexico, and is called the mountain-cat by Seba.

9. The thous, has a fmooth, crooked tail. The upper part of his body is grey, and the belly is white. He is about the fize of a large cat, and is found at Surinam.

CANIS, the DOG-FISH, a name given to feveral fpecies of fqualus. See SQUALUS.

CANIS *major*, in aftronomy, a conftellation of the fouthern hemifphere.

CANIS *minor*, CANICULUS, or CANICULA, in aftronomy, a conftellation of the northern hemifphere.

CANKER, a difeafe incident to trees, proceeding chiefly from the nature of the foil. It makes the bark rot and fall. If the canker be in a bough, cut it off; in a large bough, at fome diftance from the tree; and in a fmall one, clofe to it: But for over-hot ftrong ground, the mold is to be cooled about the roots with pond-mud, and cow-dung.

CANNA, in botany, a genus of the monandria monogynia clafs. There are four fpecies of this plant, all natives of the Indies.

CANNABIS, hemp, in botany, a genus of the diœcia pentandria clafs. The calix of the male is divided into five fegments, and it has no corolla. The calix of the female confifts of one leaf, open at the fide; it has two ftyli; and the nut or capfule confifts of two valves. There is but one fpecies, *viz.* the fativa, or common hemp, a native of India. For the method of cultivating and preparing hemp, fee FLAX, and HEMP.

CANNACORUS, in botany. See CANNA.

CANNEL-COAL, a fubftance which has a long time, though with very little reafon, been confounded, both by authors and druggifts, with jet. It is dug up in many parts of England in great abundance, particularly in Lancafhire, where it is burnt as common fuel. It is worked into toys and utenfils of various kinds, under the name of jet. In medicine, it is faid to be good in the colic; but the prefent practice takes no notice of it.

CANNON, in the military art, an engine or fire-arm for throwing iron, lead, or ftone bullets, by force of gunpowder.

Cannons at firft were called bombardæ, from the noife they made. They had likewife the name of culverin, bafilifk, *&c.* from the beafts that were reprefented upon them; and the Spaniards, from devotion, gave them the name of faints; witnefs the twelve apoftles which Charles V. ordered to be caft at Malaga, for his expedition to Tunis.

The metal of which cannons are compofed, is either iron, or which is more ufual, a mixture of copper, tin, and brafs; the tin being added to the copper,

per, to make the metal more denſe and compact; ſo that the better and heavier the copper is, the leſs tin is required. Some to an hundred pounds of copper, add ten of tin, and eight of braſs; others ten of tin, five of braſs, and ten of lead. The ſieur Bereau pretends, that when old pieces of metal are uſed, the founder ought to add to one hundred weight of that metal, twenty-five pounds of good copper, and five pounds of tin. Braudius deſcribes a method of making cannon of leather; and it is certain the Swedes made uſe of ſuch in the long war of the laſt century; but theſe burſt too eaſily to have much effect. With regard to iron cannon, they are not capable of ſo much reſiſtance as thoſe of braſs; but as they are leſs expenſive, they are often uſed on board of ſhips, and alſo in ſeveral fortified places.

Cannons are diſtinguiſhed by the diameters of the balls they carry. The rule for their length is, that it be ſuch as that the whole charge of powder be on fire, before the ball quit the piece. If it be too long, the quantity of air to be drawn out before the ball, will give too much reſiſtance to the impulſe; and that impulſe ceaſing, the friction of the ball againſt the ſurface of the piece will take off from the motion.

In former days, cannon were made much longer than they are now; but experience has taught us, that a ball moves with a greater impetus through a leſs ſpace than a greater: and accordingly it is found, that an iron ball of forty-eight pound weight goes farther from a ſhort cannon, than another ball of ninety-ſix pound out of a longer piece; whereas, in other reſpects, it is certain, the larger the bore and ball, the greater the range.

It is found too, by experience, that of two cannons of equal bore, but different lengths, the longer requires a greater charge of powder than the ſhorter. The ordinary charge of a cannon is, for the weight of its gun-powder to be half that of its ball.

We ſhall here ſubjoin a table exhibiting the names of the ſeveral cannon, their length, their weight, and that of their ball.

Names of cannon.	weight of an iron ball.		weight of the cannon.	length of the cannon.	
	lb.	oz.	lb.	f.	inch.
Cannon royal	48	0	8000	12	0
Demi cannon large	36	0	6000	12	0

Baſe	0	5	200	4	6

Cannon are likewiſe diſtinguiſhed according to the diameter of their mouth, or calibre. This calibre is divided, in conſequence of an order from the king of France, into thirty-ſix parts, in order to determine by theſe parts the dimenſions of the different moulds for cannon. We hope the reader, then, will not be diſſatisfied to find an account of the dimenſions of the ſeveral parts of cannon of five different calibres, as they are regulated by that order of the king of France, on Oct. 7, 1732, in the following table:

Pieces of cannon	of 24			of 16			of 12			of 8			of 4		
	feet.	inch.	lines.	feet.	inch.	lines.	feet.	inch.	lines.	feet.	inch.	lines.	feet.	inch.	lines.

CANNON, with letter-founders and printers, the name of the largest fize of the letters they ufe.

CANNULA, in furgery, a tube made of different metals, principally of filver and lead, but fometimes of iron.

They are introduced into hollow ulcers, in order to facilitate a difcharge of pus or any other fubftance; or into wounds, either accidental or artificial, of the large cavities, as the thorax or abdomen: they are ufed in the operation of branchotomy, and by fome, after cutting for the ftone, as a drain for the urine.

Other cannulas are ufed for introducing cauteries, either actual or potential, in hollow parts, in order to guard the parts adjacent to that to be cauterifed, from injury. They are of various figures; fome being oval, fome round, and others crooked.

CANOE, a fmall boat, made of the trunk of a tree, bored hollow; and fometimes alfo of pieces of bark fewed together.

It is ufed by the natives of America to go a-fifhing in the fea, or upon fome other expedition, either by fea, or upon the rivers and lakes.

CANON, commonly called prebendary, a perfon who poffeffes a prebend, or revenue allotted for the performance of divine fervice in a cathedral or collegiate church. Originally, canons were only priefts, or inferior ecclefiaftics, who lived in community, refiding near the cathedral church to affift the bifhop, depending entirely on his will, fupported by the revenues of his bifhopric, and living in the fame houfe as his domeftics or counfellors, *&c.* By degrees thefe communities of priefts, fhaking off their dependence, formed feparate bodies; in time they freed themfelves from their rules, and at length ceafed to live in a community. It is maintained, that the colleges of canons, which have been introduced into each cathedral, were not in the ancient church, but are of modern appointment.

In the Romifh church, when a perfon is promoted to the office of a canon, he muft be prefented in a very ceremonious manner to the chapter, who affemble in the cathedral, in order to receive him: he kiffes the altar thrice, after which he goes and takes his place in the choir; he afterwards makes his confeffion of faith aloud, and fwears to obferve the ordinances of the church and his holinefs the pope; being thus folemnly inftalled, he is impowered to affift at the chapter, to chaunt the office of the choir, *&c.*

Canons are of various kinds, as,

Cardinal-CANONS, thofe attached, or, as the Latins call it, *incardinati*, to a church, as a prieft is to a parifh.

Domicellory-CANONS, young canons, who, not being in orders, had no right in any particular chapters.

Expectative-CANONS were fuch as, without having any revenue or prebend, had the titles and dignities of canons, a voice in the chapter, and a place in the choir, till fuch time as a prebend fhould fall.

Foreign CANONS, fuch as did not officiate in the canonries to which they belonged. To thefe were oppofed manfionary canons.

Regular CANONS, thofe who ftill live in community, and who, like religious, have, to the practice of their rules, added the folemn profeffion of vows.

Tertiary CANON, a perfon who had only the third part of the revenues of the canonicate.

CANON, in an ecclefiaftical fenfe, a law, rule, or regulation of the policy and difcipline of a church, made by councils either general, national, or provincial.

CANONS *of the apoftles*, a collection of ecclefiaftical laws, which, though very ancient, were not left us by the apoftles. It is true, they were fometimes called apoftolic canons; but this means no more than that they were made by bifhops, who lived foon after the apoftles, and were called apoftolical men. They confift of regulations, which agree with the difcipline of the fecond and third centuries: The Greeks generally count eighty-five, but the Latins receive only fifty, nor do they obferve all thefe.

CANON *of mafs*, in the Romifh church, the name of a prayer which the prieft reads low to himfelf, the people kneeling.

In this part of the mafs, the prieft particularly mentions fome perfons for whom he is going to offer the facrifices, and prays to God for the redemption of their fouls, the hopes of their falvation, *&c.*

Pafchal CANON, a table of the moveable feafts, fhewing the day of Eafter, and the other feafts depending on it, for a cycle of nineteen years.

CANON *of fcripture*, a catalogue or lift of the infpired writings, or fuch books of the Bible as are called canonical; becaufe they are in the number of thofe books which are looked upon as facred, in oppofition to thofe which are either not acknowledged as divine books, or are rejected as heretical and fpurious, and are called apocryphal.

CANON, in monaftic orders, a book wherein the religious of every convent have a fair tranfcript of the rules of their order, frequently read among them, as their local ftatutes.

CANON is alfo ufed for the catalogue of faints acknowledged and canonized in the Romifh church.

CANON, in mufic, a fhort compofition of two or more parts, in which one leads, and the other follows: Or it is a line of any length, fhewing, by its divifions, how mufical intervals are diftinguifhed, according to the ratios, or proportions, that the founds terminating the intervals, bear one to another, when confidered according to their degree of being acute or grave.

CANON-LAW, a collection of ecclefiaftical laws, ferving as the rule and meafure of church-government.

The power of making laws was exercifed by the church before the Roman empire became Chriftian. The canon-law that obtained throughout the Weft, till the twelfth century, was the collection of canons made by Dionyfius Exiguus in 520, the capitularies of Charlemagne, and the decrees of the popes, from Sircius to Anaftafius.

The canon-law, even when papal authority was at its height in England, was of no force when it was found to contradict the prerogative of the king, the laws,

laws, ſtatutes, and cuſtoms of the realm, or the doctrine of the eſtabliſhed church.

The eccleſiaſtical juriſdiction of the ſee of Rome in England, was founded on the canon-law; and this created quarrels between kings and ſeveral archbiſhops and prelates, who adhered to the papal uſurpation.

Beſides the foreign canons, there were ſeveral laws and conſtitutions made here for the government of the church; but all theſe received their force from the royal aſſent: And if, at any time, the eccleſiaſtical courts did, by their ſentence, endeavour to enforce obedience to ſuch canons, the courts at common law, upon complaints made, would grant prohibitions. The authority veſted in the church of England of making canons, was aſcertained by a ſtatute of Henry VIII. commonly called the act of the clergy's ſubmiſſion; by which they acknowledged, that the convocation had been always aſſembled by the king's writ; ſo that though the power of making canons reſided in the clergy met in convocation, their force was derived from the authority of the king's aſſenting to, and confirming them.

The old canons continued in force till the reign of James I., when the clergy being aſſembled in convocation, the king gave them leave to treat and conſult upon canons; which they did, and preſented them to the king, who gave them the royal aſſent: Theſe were a collection out of the ſeveral preceding canons and injunctions. Some of theſe canons are now obſolete. In the reign of Charles I. ſeveral canons were paſſed by the clergy in convocation.

CANONESS, in the Romiſh church, a woman who enjoys a prebend, affixed, by the foundation, to maids, without their being obliged to renounce the world, or make any vows.

CANONIZATION, a ceremony in the Romiſh church, by which perſons deceaſed are ranked in the catalogue of the ſaints. It ſucceeds beatification. See BEATIFICATION.

Before a beatified perſon is canonized, the qualifications of the candidate are ſtrictly examined into, in ſome conſiſtories held for that purpoſe; after which one of the conſiſtorial advocates, in the preſence of the pope and cardinals, makes the panegyric of the perſon who is to be proclaimed a ſaint, and gives a particular detail of his life and miracles: Which done, the holy father decrees his canonization, and appoints the day.

On the day of canonization, the pope officiates in white, and their eminences are dreſſed in the ſame colour. St Peter's church is hung with rich tapeſtry, upon which the arms of the pope, and of the prince or ſtate requiring the canonization, are embroidered in gold and ſilver. An infinite number of lights blaze all round the church, which is crowded with pious ſouls, who wait, with a devote impatience, till the new ſaint has made his public entry, as it were, into paradiſe, that they may offer up their petitions to him, without danger of being rejected.

The following maxim, with regard to canonization, is now obſerved, though it has not been followed above a century, *viz.* not to enter into the inquiries prior to canonization, till fifty years, at leaſt, after the death of the perſon to be canonized. By the ceremony of canonization, it appears, that this rite of the modern Romans, has ſomething in it very like the apotheoſis or deification of the ancient Romans, and in all probability owes its riſe to it; at leaſt, ſeveral ceremonies of the ſame nature are conſpicuous in both.

CANONOR, a town on the Malabar coaſt, in the Hither India: E. long. 75°, N. lat. 10°.

Here the Dutch have a fort and factory, which they took from the Portugueſe in 1663.

CANONRY, the benefice filled by a canon. It differs from a prebend, in that the prebend may ſubſiſt without the canonicate; whereas the canonicate is inſeparable from the prebend; again, the rights of ſuffrages, and other privileges, are annexed to the canonicate, and not to the prebend.

CANOPUS, in aſtronomy, a ſtar of the firſt magnitude in the rudder of Argo, a conſtellation of the ſouthern hemiſphere. See ASTRONOMY, *Of the fixed ſtars*.

CANTABRICA, in botany, a ſynonime of a ſpecies of convolvulus. See CONVOLVULUS.

CANTALIVERS, in architecture, pieces of wood framed into the front or other ſides of a houſe, to ſuſpend the mouldings and eyes over it.

CANTAR, or CANTARO, in commerce, a weight uſed in Italy, particularly at Leghorn, to weigh ſome ſorts of merchandiſes.

There are three ſorts of cantari, or quintals, one weighs 150 pounds, the other 151, and the third 160: The firſt ſerves to weigh alum and cheeſe, the ſecond is for ſugar, and the third for wool and codfiſh.

CANTAR is alſo a meaſure of capacity uſed at Cochin, and containing four rubis.

CANTATA, in muſic, a ſong or compoſition, intermixed with recitatives, airs, and different movements, chiefly intended for a ſingle voice, with a thorough baſs, though ſometimes for other inſtruments.

The cantata, when performed with judgment, has ſomething in it very agreeable; the variety of the movement not clogging the ear, like other compoſitions. It was firſt uſed in Italy, then in France, whence it paſſed to us.

CANTERBURY, the capital city of Kent, fifty-five miles eaſt of London, and ſixteen north-weſt of Dover: E. long. 1° 15′, N. lat. 51° 16′.

It is a county of itſelf, and the ſee of an archbiſhop, who is primate and metropolitan of all England. It is a large, populous, and trading city; has a good ſilk manufactory, and ſends two members to parliament.

CANTERBURY-BELL, in botany. See CAMPANULA.

CANTHARIS, in zoology, a genus of inſects belonging to the order of inſecta coleoptera. The feelers of this genus are ſetaceous; the breaſt is marginated, and ſhorter than the head; the elytra, or wing-caſes, are flexile; and the ſides of the belly are plaited and papillous. Linnæus enumerates 27 ſpecies of the cantharis, moſt of them to be found in differents parts of Europe,

Europe. The cantharis ufed in making bliftering plafters, is ranked under a different genus, *viz.* the Meloe. See MELOE.

CANTICLES, a canonical book of the Old Teftament. The Talmudifts afcribe it to Hezekiah, but the learned are agreed that king Solomon was the author of it; and his name is prefixed to it in the title of the Hebrew text, and of the ancient Greek verfion.

CANTO, in mufic, the treble, or at leaft the higher part of a piece.

This word more properly fignifies the firft treble, unlefs the word *fecundo*, for the fecond, or *ripieno*, for the treble of the grand chorus, be added.

CANTON, in geography, denotes a fmall country, or diftrict, conftituting a diftinct government: fuch are the cantons of Switzerland.

CANTON is alfo the name of a large, populous, and wealthy city and port-town of China, fituated on the river Ta, about fifty miles from the Indian ocean: E. long. 112° 30′, N. lat. 23° 25′.

It is a fortified place, within the walls of which no Chriftians are permitted to enter, notwithftanding their great trade thither; it being from thence that they import all manner of Chinefe goods, as china-ware, tea, cabinets, raw and wrought filks, gold-duft, *&c.*

CANTONING, in the military art, is the allotting diftinct and feparate quarters to each regiment of an army; the town where they are quartered, being divided into fo many cantons, or divifions, as there are regiments.

CANTRED, or CANTREF, fignifies an hundred villages, being a Britifh word, compounded of the adjective *cant*, i. e. hundred, and *tref*, a town or village. In Wales, fome of the countries are divided into cantreds, as in England into hundreds.

CANVAS, in commerce, a very clear unbleached cloth of hemp, or flax, wove very regularly in little fquares. It is ufed for working tapeftry with the needle, by paffing the threads of gold, filver, filk, or wool, through the intervals or fquares.

CANVAS is alfo a coarfe cloth of hemp, unbleached, fomewhat clear, which ferves to cover womens ftays, alfo to ftiffen mens cloaths, and to make fome other of their wearing-apparel, *&c.*

CANVAS is alfo a very coarfe cloth made of hemp, unbleached, ferving to make towels, and anfwering other domeftic purpofes. It is alfo ufed to make fails for fhipping, *&c.*

CANVAS is ufed among the French, for the model and firft words, where an air or piece of mufic is compofed, and given to a poet to regulate and finifh.

CANATUS, in ornithology, the trivial name of a fpecies of tringa. See TRINGA.

CANZONE, in mufic, fignifies, in general, a fong where fome little figures are introduced: But it is fometimes ufed for a fort of Italian poem, ufually pretty long, to which mufic may be compofed in the ftyle of a cantata. If this term be added to a piece of inftrumental mufic, it fignifies much the fame as cantata: If placed in any part of a fonata, it implies the fame meaning as *allegro*, and only denotes that the part to which it is prefixed, is to be played or fung in a brifk and lively manner.

CANZONETTA, a diminutive of canzone, denoting a little fhort fong: The canzonette neapolitane have two ftrains, each whereof is fung twice over, as the vaudevilles of the French: The canzonette ficiliane are a fpecies of jigg, the meafure whereof is ufually twelve eights, and fix eights, and fometimes both, as rondeaus.

CAP, a part of drefs made to cover the head, much in the figure thereof.

The ufe of caps and hats is referred to the year 1449, the firft feen in thefe parts of the world being at the entry of Charles VII. into Rouen: from that time they began to take place of the hoods, or chaperoons, that had been ufed till then. When the cap was of velvet, they called it mortier; when of wool, fimply bonnet. None but kings, princes, and knights, were allowed the ufe of the mortier. The cap was the head-drefs of the clergy and graduates: Churchmen and members of univerfities, ftudents in law, phyfic, *&c.* as well as graduates, wear fquare caps in moft univerfities. Doctors are diftinguifhed by peculiar caps, given them in affuming the doctorate. Pafquier fays, that the giving the cap to ftudents in the univerfities, was to denote that they had acquired full liberty, and were no longer fubject to the rod of their fuperiors, in imitation of the ancient Romans, who gave a pileus or cap to their flaves, in the ceremony of making them free. The cap is alfo ufed as a mark of infamy in Italy. The Jews are diftinguifhed by a yellow cap at Lucca, and by an orange one in France.

CAP *of maintenance*, one of the regalia, or ornaments of ftate belonging to the kings of England, before whom it was carried at the coronation, and other great folemnities. Caps of maintenance are alfo carried before the mayors of the feveral cities in England.

CAPE, in geography, an high land running out with a point, into the fea, as Cape-Nord, Cape-Horn, the Cape of Good-Hope, *&c.*

CAPE *of Good-Hope*. See GOOD-HOPE.

CAPE-*coaft-caftle*, the principal Britifh fort and fettlement on the gold-coaft of Guinea, fituated under the meridian of London, in 5° N. lat.

CAPELLA, in aftronomy, a bright fixed ftar in the left fhoulder of the conftellation auriga.

CAPER, in botany. See CAPPARIS.

CAPERQUIN, a town of Ireland, in the county of Waterford, and province of Munfter, fituated on the river Blackwater: W. long. 7° 50′, and N. lat. 52° 5′.

CAPHAR, a duty which the Turks raife on the Chriftians, who carry or fend merchandifes from Aleppo to Jerufalem, and other places in Syria.

This duty of caphar was firft impofed by the Chriftians themfelves, when they were in poffeffion of the Holy land, for the maintenance of the troops, which were planted in difficult paffes, to obferve the Arabs, and prevent their incurfions. It is ftill continued, and much increafed by the Turks, under pretence of defending the Chriftians againft the Arabs, with whom, never-

neverthelefs, they keep a fecret intelligence, favouring their excurfions and plunders.

CAPI-AGA, or CAPOU-AGASSI, a Turkifh officer, who is, as it were, grand-mafter of the feraglio.

He is the firft in dignity and repute of all the white eunuchs, and is always near the Grand Signior's perfon. It is he who introduces embaffadors to audience; and all great affairs pafs through his hands before they come to that of the prince.

CAPIAS, in law, a writ of two forts, one before judgement in an action, and the other after: That before judgment is called *capias ad refpondendum*, where an original is fued out, *&c.* to take the defendant, and make him anfwer the plantiff; and that after judgement is the *capias ad fatisfaciendum*, &c.

CAPIGI, in the Turkifh affairs, the name of certain inferior officers belonging to the feraglio, to the number of five hundred, whofe bufinefs is to affift the janizaries in guarding the firft and fecond gate of that palace; whence alfo the name capighi, which fignifies a gate.

CAPILLAMENT, in a general fenfe, fignifies a hair, whence the word is applied to feveral things, which, on account of their length or their finenefs, refemble hairs: As,

CAPILLAMENTS *of the nerves*, in anatomy, the fine fibres, or filaments, whereof the nerves are compofed.

CAPILLARY, in a general fenfe, an appellation given to things on account of their extreme finenefs, or refembling hair.

CAPILLARY *tubes*, in phyfics, little pipes whofe canals are extremely narrow, their diameter being only a half, third, or fourth of a line. See HYDROSTATICS.

CAPILLUS *veneris*, in botany. See ADIANTUM.

CAPITAL, in geography, denotes the principal city of a kingdom, province, or ftate.

CAPITAL, among merchants, traders, and bankers, fignifies the fum of money which individuals bring to make up the common ftock of a partnerfhip.

CAPITAL *crime*, fuch a one as fubjects the criminal to capital punifhment, that is, the lofs of life.

CAPITAL, in architecture, the uppermoft part of a column or pilafter, ferving as the head, or crowning, and placed immediately over the fhaft, and under the entablature. See ARCHITECTURE.

CAPITANATE, a province of the kingdom of Naples, fituated on the gulf of Venice, and having the province of Molife on the north, and the Principate on the fouth.

CAPITANIA, in geography, an appellation given to the twelve governments eftablifhed by the Portuguefe in the Brafils.

CAPITATION, a tax or impofition raifed on each perfon in confideration of his labour, induftry, office, rank, *&c.* It is a very ancient kind of tribute. The Latins call it *tributum*, by which taxes on perfons are diftinguifhed from taxes on merchandife, which were called *vectigalia*.

Capitations are never practifed among us but in exigencies of ftate. In France, the capitation was introduced by Lewis XIV. in 1695, and is a tax very different from the taille, being levied from all perfons whether they be fubject to the taille or not. The clergy pay no capitation, but the princes of the blood are not exempted from it.

CAPITOL, in antiquity, a caftle on the Mons Capitolinus at Rome, where there was a temple dedicated to Jupiter, in which the fenate anciently affembled. The capitol confifted of three parts; a nave, facred to Jupiter; and two wings, the one confecrated to Juno, and the other to Minerva: It was afcended to by ftairs; the frontifpiece and fides were furrounded with galleries, in which thofe who were honoured with triumphs entertained the fenate at a magnificent banquet, after the facrifices had been offered to the gods.

Both the infide and outfide were enriched with infinite ornaments, the moft diftinguifhed of which was the ftatue of Jupiter, with his golden thunder-bolt, his fceptre, and crown. In the capitol alfo were a temple to Jupiter the guardian, and another to Juno, with the mint; and on the defcent of the hill was the temple of Concord.

This beautiful edifice contained the moft facred depofits of religion, fuch as the ancylia, the books of the fybils, *&c.*

CAPITOLINE *games*, annual games inftituted by Camillus, in honour of Jupiter Capitolinus, and in commemoration of the capitol's not being taken by the Gauls. Plutarch tells us, that a part of the ceremony confifted in the public crier's putting up the Hetrurians to fale by auction: They alfo took an old man, and, tying a golden bulla about his neck, expofed him to the public derifion. Feftus fays, they alfo dreffed him in a prætexta. There was another kind of capitoline games, inftituted by Domitian, wherein there were rewards and crowns beftowed on the poets, champions, orators, hiftorians, and muficians. Thefe laft capitoline games were celebrated every five years, and became fo famous, that inftead of calculating time by luftra, they began to count by capitoline games, as the Greeks did by olympiads. It appears, however, that this cuftom was not of long continuance.

CAPITOUL, an appellation given to the chief magiftrates of Tholoufe, on account of their meeting in a place called the Capitol: They are eight in number, are chofen annually, and have each the government of a capitoulate, or precinct, like the wards of London.

CAPITULATION, in military affairs, a treaty made between the garrifon or inhabitants of a place befieged, and the befiegers, for the delivering up the place on certain conditions.

The moft honourable and ordinary terms of capitulation are, to march out at the breach, with arms and baggage, drums beating, colours flying, a match lighted at both ends, and fome pieces of cannon, waggons and convoys for their baggage, and for the fick and wounded.

CAPITULATION, in the German polity, a contract which the emperor makes with the electors, in the name of all the princes and ftates of the empire, before he is declared emperor, and which he ratifies before

fore he is raifed to that fovereign dignity. The principal points which the emperor undertakes to obferve, are, 1. To defend the church and the empire. 2. To obferve the fundamental laws of the empire. And, 3. To maintain and preferve the rights, privileges, and immunities of the electors, princes, and other ftates of the empire, fpecified in the capitulation. Thefe articles and capitulations are prefented to the emperor by the electors only, without the concurrence of the other ftates, who have complained from time to time of fuch proceedings; and in the time of the Weftphalian treaty, in 1648, it was propofed to deliberate in the following diet, upon a way of making a perpetual capitulation; but the electors have always found means of eluding the execution of this article. In order however to give fome fatisfaction to their adverfaries, they have inferted in the capitulations of the emperors, and in that of Francis I. in particular, a promife to ufe all their influence to bring the affair of a perpetual capitulation to a conclufion. Some German authors own, that this capitulation limits the emperor's power; but maintain that it does not weaken his fovereignty: Though the moft part maintain, that he is not abfolute, becaufe he receives the empire under conditions which fet bounds to an abfolute authority.

CAPNOIDES, in botany, the trivial name of a fpecies of fumaria. See FUMARIA.

CAPON, a cock-chicken, gelded as foon as left by the dam, or as foon as he begins to crow. They are of ufe either to lead chickens, ducklings, pheafants, *&c.* and defend them from the kites and buzzards; or to feed for the table, they being reckoned more delicate than either a cock or a hen.

CAPPACIA, a town of the hither principate, in the kingdom of Naples. It is a bifhop's fee, and fituated about fifty-five miles fouth-eaft of the city of Naples: E. long. 15° 20′, and N. lat. 40° 40′.

CAPPARIS, in botany, a genus of the polyandria monogynia clafs. The calix confifts of four coriaceous leaves; the corolla has four petals; the ftamina are long; and the capfule is flefhy within, unilocular, and fupported by a pedunculus. There are ten fpecies, none of which are natives of Britain

CAPRA, or GOAT, a genus of quadrupeds belonging to the order of pecora. The horns are hollow, turned upwards, erect, and fcabrous. There are eight fore-teeth in the under jaw, and none in the upper; and they have no dog-teeth. This genus confifts of twelve fpecies, *viz.*

1. The hircus, or common goat, with arched carinated horns, and a long beard. The goat of Angora is only a variety of this fpecies; its hair is white, and hangs down to the feet; and the ears are plain and pendent. The common goat is a native of the eaftern mountains. See Plate LXIII.

The goat is an animal of more fagacity than the fheep. Inftead of having an antipathy at mankind, they voluntarily mingle with them, and are eafily tamed. Even in uninhabited countries, they betray no favage difpofitions. In the year 1698, an Englifh veffel having put in to the ifland of Bonovifta, two negroes came aboard, and offered gratis to the captain as many goats as he pleafed. The captain expreffed his aftonifhment at this offer. But the negroes replied, that there were only twelve perfons in the ifland; that the goats had multiplied to fuch a degree, that they were become extremely troublefome; and that, inftead of having any difficulty in catching them, they followed the men where-ever they went, and were fo obftinately officious, that they could not get quit of them upon any account whatever.

Goats are fenfible of careffes, and capable of a confiderable degree of friendfhip. They are ftronger, more agile, and lefs timid than fheep. They have a lively, capricious, and wandering difpofition; are fond of high and folitary places; and frequently fleep upon the very points of rocks. They are more eafily fupported than any other animal of the fame fize; for there is hardly an herb or the bark of a tree, which they will not eat with pleafure. Neither are they liable to fo many difeafes as fheep: They can bear heat and cold with lefs inconvenience. The actions and movements of animals depend more upon the force and variety of their fenfations, than the ftructure of their bodies: The natural inconftancy or fancifulnefs of goats is accordingly expreffed by the irregularity of their actions: They walk, ftop fhort, run, jump, fhew, and hide themfelves, as it were by mere caprice, and without any other caufe than what arifes from the natural vivacity of their temper.

The buck will copulate when he is a year old, and the female when fhe is feven months. But as this is rather premature, they are generally reftrained till they be eighteen months or two years. The buck is bald, beautiful, and vigorous; one is fufficient to ferve 150 females. A buck for propagation fhould be large, handfome, and about two years of age; his neck fhould be fhort, and flefhy; his head flender; his ears pendent; his thighs thick; his limbs firm; his hair black, thick, and foft; and his beard fhould be long, and bufhy. The females are generally in feafon from September to the end of November. The time of going with young is five months. They generally produce one kid, fometimes two, feldom three, and never more than four; and continue fruitful till they be feven years of age: But a buck is feldom kept after he is five.

Goat's flefh is not fo good as mutton: The rank fmell of the buck does not proceed from the flefh, but from the fkin.

The food of this animal cofts next to nothing, as it lives moftly upon fuch plants as are rejected by other cattle, and can fupport itfelf even upon the moft barren mountains. But their produce is valuable. Cheefe is made of their milk, which befides is reckoned good in confumptions, and other difeafes. Their flefh, tallow, hair, and hides, are all ufeful and faleable commodities.

2. The ibex, has large knotty horns reclined upon its back, is of a yellowifh colour, and its beard is black. This fpecies is a native of Crete; and is likewife to be met with in the mountains of fome of the northern parts of Europe.

3. The

Plate LXIII.

A. Bell Sculp.t

3. The mambrica, with reclined horns, about the length of the neck, pendent ears, and a beard. It is a native of India.

4. The rupicapra, or ſhamoy-goat, has erect and hooked horns. It inhabits the inacceſſible mountains of Switzerland. The body is of a duſky red colour; but the front, top of the head, gullet, and inſide of the ears are white; the under part of the tail is blackiſh; and the upper lip is a little divided. They ſeldom deſcend from the mountains but in hard winters, when they come down to feed upon the branches and barks of fir-trees, *&c.* On occaſions of this kind, one of the herd always keeps watch to give notice to the reſt of any approaching danger.

5. The depreſſa, is an American goat, with ſmall depreſſed horns, bent inwards and lying upon the head. It is about the ſize of a kid; and the hair is long and pendulous.

6. The reverſa, is likewiſe an American goat, with erect horns curved back at the points. It is about the ſize of a kid of a year old.

7. The gazella, is an Indian goat, with long, erect, cylindrical horns, annulated near the baſe.

8. The cervicapra, is likewiſe an Indian goat, with plaited, cylindrical horns. The hair near the horns is longer than in any other part of the body.

9. The Bezoartica, or Bezoar-goat, is bearded, and has cylindrical, arched, and wholly annulated horns. It is a native of Perſia. The bezoar is found in one of the ſtomachs called *abomaſus*. See BEZOAR.

10. The dorcas, or antelope, has cylindrical, annulated horns, bent backward, contorted, and ariſing from the front between they eyes. It is a native of Africa and Mexico.

11. The tartarica, has cylindrical, ſtrait, annulated horns, diaphonous at the points. It has no beard, and is found in the northern parts of Aſia.

12. The ammon, has ſemicircular, plain, white horns, and no beard. It is about the ſize of a ram, and is a native of Siberia.

CAPRAIA, an iſland on the coaſt of Tuſcany, about thirty miles ſouth-weſt of Leghorn: E. long. 11°, and N. lat. 43° 15′.

CAPRARIA, in botany, a genus of the didynamia angioſpermia claſs. The calix is divided into five ſegments; the corolla is bell ſhaped, and divided into five parts; the capſule has two valves, and contains many ſeeds. There are three ſpecies, none of them natives of Britain.

CAPRAROLA, a town of St Peter's patrimony in Italy, about twenty miles north of the city of Rome, and eight ſouth of Viterbo: E. long. 13°, and N. lat. 42° 30′.—It is a biſhop's ſee.

CAPRI, or CAPREA, a city and iſland at the entrance of the gulf of Naples, about twenty miles ſouth of that city: E. long. 14° 50′, and N. lat. 40° 45′.

The iſland is only four miles long, and one broad; the city is a biſhop's ſee, ſituated on a high rock, at the weſt end of the iſland.

CAPRICORN, in zoology. See MORDELLA.

CAPRICORN-*beetle*. See CERAMBYX.

CAPRICORN, in aſtronomy, one of the twelve ſigns of the zodiac.

Tropic of CAPRICORN, a leſſer circle of the ſphere, which is parallel to the equinoxial, and at 23° 30′ diſtance from it ſouthwards.

CAPRIFICATION, a method uſed in the Levant, for ripening the fruit of the domeſtic fig-tree, by means of inſects bred in that of the wild fig-tree.

It is ſaid, that theſe figs will never come to maturity, unleſs wounded by the inſects depoſiting their eggs. Poſſibly the reaſon of this effect, may be their lacerating the veſſels of the fruit, and thereby deriving thither a greater quantity of nutricious juice.

Plumbs and pears, wounded in the ſame manner, are found to ripen ſooneſt, and the pulp about the wound has a more exquiſite taſte than the reſt.

CAPRIFICUS, in botany. See FICUS.

CAPRIFOLIUM, in botany. See LONICERA.

CAPRIMULGUS, GOAT-SUCKER, or FERN-OWL, in ornithology, a genus of birds belonging to the order of paſſeres. The beak is incurvated, ſmall, tapering, and depreſſed at the baſe; the hairs at the mouth, which it opens very wide, are placed in a row. There are two ſpecies, *viz.* the Europæus, with the tubes of the noſtrils hardly viſible. It is a native of Europe, and feeds upon moths and nocturnal inſects. This bird is ſaid to ſuck goats in the night. 2. The Americacanus, has the tubes of the noſtrils very conſpicuous. This is a night-bird, and is found in America.

CAPRIOLES, in the menage, leaps that a horſe makes in the ſame place, without advancing, in ſuch a manner, that when he is at the height of the leap, he jerks out with his hinder legs even and near. It is the moſt difficult of all the high menage. It differs from a croupade in this, that in a croupade the horſe does not ſhew his ſhoes; and from a ballotade, becauſe in this he does not jerk out. To make a horſe work well at caprioles, he muſt be put between two pillars, and taught to raiſe firſt his fore-quarters, and then his hind-quarters, while his fore are yet in the air, for which end you muſt give the whip and the poinſon.

CAPSICUM, or GUINEA-PEPPER, a genus of the pentandria monogynia claſs. The corolla is rotated, and the berry wants juice. There are two ſpecies, both natives of the Indies. The ſeeds are uſed in ſauces and pickles.

CAPSQUARES, in gunnery, ſtrong plates of iron which come over the trunnions of a gun, and keep it in the carriage.

They are faſtened by a hinge to the prize-plate, that they may lift up and down, and form a part of an arch in the middle to receive a third part of the thickneſs of the trunnions; for two thirds are let into the carriage, and the other end is faſtened by two iron wedges, called the fore-locks and keys.

CAPSTAN, or MAIN CAPSTAN, in a ſhip, a great piece of timber in the nature of a windlaſs, placed next behind the main-maſt, its foot ſtanding in a ſtep on the lower deck, and its head between the upper decks; formed into ſeveral ſquares with holes in them. Its

ufe is to weigh the anchors, to hoife up or ftrike down top-mafts, to heave any weighty matter, or to ftrain any rope that requireth a main force.

Jear CAPSTAIN is placed between the main-maft and the mizen, and ferves to ftrain any rope, heave up on the jear rope or upon the viol, or hold off by at the weighing of an anchor.

CAPSTAN-*bars*, the pieces of wood that are put into the capftan-holes, to heave up any thing of weight into the fhip.

Pawl of a CAPSTAN, a fhort piece of iron made faft to the deck, and refting upon the whelps, to keep the capftan from recoiling, which is of dangerous confequence.

Whelps of a CAPSTAN are fhort pieces of wood, made faft to it, to keep the cable from coming too nigh, in turning it about.

Pawling the CAPSTAN, is ftopping it from turning by means of the pawl.

Come up CAPSTAN, or *launch out the* CAPSTAN, that is, flacken the cable which you heave by.

CAPSULE, in a general fenfe, denotes a receptacle, or cover in form of a bag.

CAPSULE, among botanifts, a fpecies of pericarpium, or feed-veffel, compofed of feveral dry elaftic valves, which ufually burft open at the points, when their feeds are ripe: It differs from a pod, in being roundifh and fhort. This kind of pericarpium fometimes contains one cell or cavity, fometimes more: In the firft cafe it is called unilocular, as it is bilocular, trilocular, *&c.* when it contains two, three, *&c.* cells or cavities.

CAPSULÆ *atrabiliariæ*, called alfo *glandulæ renales*, and *renes fuccenturiati*. See p. 269.

CAPTAIN, a military officer, whereof there are various kinds, according to their commands.

CAPTAIN *of a troop or company*, an inferior officer, who commands a troop of horfe, or company of foot, under a colonel. In the fame fenfe we fay, captain of dragoons, of grenadiers, of marines, of invalids, *&c.*

In the horfe and foot guards, the captains have the rank of colonels.

CAPTAIN *general*, he who commands in chief.

CAPTAIN *lieutenant*, he who with the rank of captain, but the pay of lieutenant, commands a troop or company in the name and place of fome other perfon who is difpenfed with on account of his quality from performing the functions of his poft.

Thus the colonel, being ufually captain of the firft company of his regiment; that company is commanded by his deputy, under the title of captain-lieutenant.

So in England, as well as in France, the king, queen, dauphin, princes, *&c.* have ufually the title of captains of the guards, *gens d' armes*, &c. the real duty of which offices is performed by captain-lieutenants.

CAPTAIN *reformed*, one who, upon the reduction of the forces, has his commiffion and company fuppreffed; yet is continued captain, either as fecond to another, or without any poft or command at all.

CAPTAIN *of militia*, he who commands a company of the militia, or trained bands. See MILITIA.

CAPTAIN *of a fhip of war*, the commanding officer of a fhip, galley, fire-fhip, or the like. This officer ranks with a colonel in the land-fervice.

CAPTAIN *of a merchant fhip*, he who has the direction of the fhip, her crew, and lading, *&c.* In fmall fhips and fhort voyages, he is more ordinarily called the mafter. In the mediterranean, he is called the patroon.

The proprietor of the veffel appoints the captain or mafter, and he is to form the crew, and chufe and hire the pilots, mates, and feamen; though, when the proprietor and mafter refide on the fame fpot, they generally act in concert together.

CAPTAIN BASHAW, or CAPONDAN BASHAW, in the polity of the Turks, fignifies the Turkifh high admiral. He poffeffes the third office of the empire, and is invefted with the fame power at fea that the vizir has on fhore. Soliman II. inftituted this office in favour of the famous Barbaroffa, with abfolute authority over the officers of the marine and arfenal, whom he may punifh, cafhier, or put to death, as foon as he is without the Dardanelles. He commands in chief in all the maritime countries, cities, caftles, *&c.* and, at Conftantinople, is the firft magiftrate of police in the villages on the fide of the Porte, and the canal of the Black-fea. The mark of his authority is a large Indian cane, which he carries in his hand, both in the arfenal and with the army.

The captain-bafhaw enjoys two forts of revenues; the one fixed, the other cafual. The firft arife from a capitation of the iflands in the Archipelago, and certain governments in Natolia and Galipoli. The latter confift in the pay of the men who die during a campaign; in a fifth of all prizes made by the begs; in the profits accruing from the labour of the flaves, whom he hires as rowers to the grand fignior; and in the contributions he exacts in all places where he paffes.

CAPTION, in Scots law, a writ iffuing under his majefty's fignet, in his majefty's name, obtained at the inftance of a creditor in a civil debt, commanding meffengers at arms and other officers of the law to apprehend and imprifon the perfon of the debtor until he pay the debt. See SCOTS LAW, title, *Sentences and their execution*.

CAPTIVITY, a punifhment which God inflicted upon his people for their vices and infidelities. The firft of thefe captivities is that of Egypt, from which Mofes delivered them; after which, are reckoned fix during the government of the judges; but the greateft and moft remarkable, were thofe of Judah and Ifrael, which happened under the kings of each of thefe kingdoms. It is generally believed, that the ten tribes of Ifrael never came back again after their difperfion; and Jofephus and St Jerom are of this opinion: neverthelefs, when we examine the writings of the prophets, we find the return of Ifrael from captivity pointed out in a manner almoft as clear as that of the tribes of Benjamin and Judah. See Hofea i. 10. xi. 12. Amos ix. 14. Ifaiah xi. 13, 14. Ezekiel xxxvii. 16, *&c.*

The captivities of Judah are generally reckoned four; the fourth and laſt of which fell in the year of the world 3416, under Zedekiah; and from this period begins the ſeventy years captivity, foretold by Jeremiah.

Since the deſtruction of the temple by the Romans, the Hebrews boaſt, that they have always had their heads, or particular princes, whom they call princes of the captivity, in the eaſt and weſt. The princes of the captivity in the eaſt governed the Jews who dwelt at Babylon, in Chaldea, Aſſyria, and Perſia; and the prince of the captivity in the weſt governed thoſe who dwelt in Judea, Egypt, Italy, and in other parts of the Roman empire. He who reſided in Judæa, took up his abode commonly at Tiberias, and aſſumed the title of Roſchabboth, head of the fathers or patriarchs. He preſided in aſſemblies, decided in caſes of conſcience, levied taxes for the expences of his viſits, and had officers under him, who were diſpatched through the provinces, for the execution of his orders. As to the princes of the captivity of Babylon, or the eaſt, we know neither the original nor ſucceſſion of them; it appears only, that they were not in being before the end of the ſecond century.

CAPTURE ſignifies, particularly, prizes taken by privateers in time of war.

CAPUA, a city of the province of Lavoro, in the kingdom of Naples, ſituated on the river Volturno, about fifteen miles north-weſt of the city of Naples: E. long. 15°, and N. lat. 41° 20′.

It is the ſee of an archbiſhop.

CAPUCHINS, in the church of Rome. See FRANCISCANS.

CAPUT *mortuum*, in chemiſtry, that thick dry matter which remains after diſtillation of any thing, but of minerals eſpecially.

CAPY-BARA, in zoology. See SUS.

CARABINE, a fire-arm, ſhorter than a muſket, carrying a ball of twenty-four in the pound, borne by the light-horſe, hanging at a belt over the left ſhoulder.

The barrel is two feet and a half long, and is ſometimes furrowed ſpirally within, which is ſaid to add to the range of the piece.

CARABINEERS, or CARABINIERS, regiments of light horſe, carrying longer carabines than the reſt, and uſed ſometimes on foot.

CARABUS, in zoology, a genus of inſects belonging to the order of inſecta coleoptera. The feelers are briſtly; the breaſt is ſhaped like a heart, and marginated; and the elytra are likewiſe marginated. There are 43 ſpecies of this genus, moſtly diſtinguiſhed by their colour.

CARACATY, a large country in the north of Aſia, extending from the wall of China to the ancient Mogoliſtan.

CARACOL, in the menage, the half turn which a horſeman makes, either to the right or left.

In the army, the horſe always make a caracol after each diſcharge, in order to paſs to the rear of the ſquadron.

CARACOL, in architecture, denotes a ſtair-caſe in a helix or ſpiral form.

CARACOLI, a kind of metal, of which the Caribbees, or natives of the Leſſer Antilles, make a ſort of ornament in the form of a creſcent, which they alſo call caracoli.

This metal comes from the main land; and the common opinion is, that it is a compound of ſilver, copper, and gold, ſomething like the Corinthian braſs among the ancients. Theſe metals are ſo perfectly mixed and incorporated together, that the compound which reſults from them, it is ſaid, has a colour that never alters, how long ſoever it remains in the ſea, or under ground. It is ſomething brittle, and they who work at it, are obliged to mix a large proportion of gold with it, to make the compound more tough and malleable.

CARACT, CARAT, or CARRAT, the name of that weight which expreſſes the degree of fineneſs that gold is of.

The mint-maſter, or cuſtom, have fixed the purity of gold at 24 caracts; though it is not poſſible ſo to purify and refine that metal, but it will want ſtill about one fourth part of a caract in abſolute purity and perfection. The caract is divided into $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, and $\frac{1}{32}$. Theſe degrees ſerve to diſtinguiſh the greater or leſſer quantity of alloy therein contained; for inſtance, gold of 22 caracts, is that which has two parts of ſilver, or of any other metal, and 22 of fine gold.

CARACT is alſo a certain weight which goldſmiths and jewelers uſe wherewith to weigh precious ſtones and pearls.

This caract weighs four grains, but ſomething lighter than the grains of other weights. Each of theſe grains is ſubdivided into $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, *&c.*

CARAGROUTH, in commerce, a ſilver-coin of the empire, weighing nine drachms. It goes at Conſtantinople for 120 aſpers. There are four ſorts of them, which are all equally current, and of the ſame value.

CARAGUATA, in botany. See TILLANDSIA.

CARAITES, in the eccleſiaſtical hiſtory of the Jews, a religious ſect among that people, who adhere cloſely to the text and letter of the ſcriptures, rejecting the rabbinical interpretations, and the cabbala. The Caraites paſs for the moſt learned of the Jewiſh doctors; they are chiefly to be met with in Poland, Muſcovy, and the eaſt: they are but few in compariſon of the bulk of the Jews, who are of the party of the rabbins: the latter have ſo great an averſion for the Caraites, that they will have no alliance, nor even converſation with them: they treat them as baſtards; and if a caraite would turn rabbiniſt, the other Jews would not receive him.

CARAMANIA, a province of Natolia, in Aſia, ſituated on the Mediterranean ſea, oppoſite to the iſland of Cyprus.

CARAMANICO, a large well-peopled town of the kingdom of Naples, in the hither Abruzzo.

CARAMANTA, the name of a province of South America, bordered on the north by the diſtrict of Carthagena;

thagena; on the east, by New Grenada; and on the south and west, by Popayan.

CARAMANTA is also the name of the capital of that province, situated in 5° 18′ N. lat.

CARANNA, a resinous substance brought from New Spain in little masses rolled up in leaves of flags. It is rarely kept in the shops, and is rejected by the catalogue of the London college, though it is still retained in the Edinburgh.

CARAPO, in ichthyology, the trivial name of a species of gymnotus. See GYMNOTUS.

CARAVAN, or CARAVANNE, in the east, signifies a company or assembly of travellers and pilgrims, and more particularly of merchants, who, for their greater security, and in order to assist each other, march in a body through the desarts, and other dangerous places, which are infested with Arabs or robbers.

There is a chief, or aga, who commands the caravan, and is attended by a certain number of janizaries, or other militia, according to the countries from whence the caravans set out; which number of soldiers must be sufficient to defend them and conduct them with safety to the places for which they are designed, and on a day appointed. The caravan encamps every evening near such wells or brooks, as their guides are acquainted with; and there is a strict discipline observed upon this occasion, as in armies in time of war. Their beasts of burden are partly horses, but most commonly camels, who are capable of undergoing a very great fatigue.

CARAVANSERA, or KARAVANSERA, a place appointed for receiving and loading the caravans.

It is commonly a large square building, in the middle of which there is a very spacious court; and under the arches or piazzas that surround it there runs a bank, raised some feet above the ground, where the merchants, and those who travel with them in any capacity, take up their lodgings as well as they can; the beasts of burden being tied to the foot of the bank. Over the gates, that lead into the court, there are sometimes little rooms, which the keepers of the caravanseras let out at a very high price to such as have a mind to be private.

The caravanseras in the east are something in the nature of the inns in Europe, only that you meet with little accommodation either for man or beast, but are obliged to carry almost every thing with you: there is never a caravansera without a well, or spring of water. These buildings are chiefly owing to the charity of the Mahometans; they are esteemed sacred dwellings, where it is not permitted to insult any person, or to pillage any of the effects that are deposited there. They even carry their precautions so far, as not to suffer any man who is not married to lodge there; because they are of opinion, that a man who has no wife is more dangerous than another.

CARAVANSERASKIER, the steward, or keeper of a caravansera.

He keeps an account of all the merchandises that are sold upon trust, and demands the payments of the sums due to the merchants for what has been sold in the caravansera, on the seller's paying two *per cent*.

CARAWAY, in botany. See CARUM.

CARBUNCLE, in natural history, a very elegant gem, whose colour is deep red, with an admixture of scarlet.

This gem was known among the ancients by the name of anthrax. It is usually found pure and faultless, and is of the same degree of hardness with the sapphire: it is naturally of an angular figure, and is found adhering, by its base, to a heavy and ferrugineous stone of the emery kind: its usual size is near a quarter of an inch in length, and two thirds of that in diameter in its thickest parts: when held up against the sun, its loses its deep tinge, and becomes exactly of the colour of a burning charcoal, whence the propriety of the name which the ancients gave it. It bears the fire unaltered, not parting with its colour, nor becoming at all the paler by it. It is only found in the East Indies, so far as is yet known, and there but very rarely.

CARBUNCLE, or ANTHRAX, in surgery, an inflammation which arises, in time of the plague, with a vesicle or blister almost like those produced by burning.

CARBUNCLE, in heraldry, a charge or bearing, consisting of eight radii, four whereof make a common cross, and the other four a saltier.

Some call these radii buttons, or staves, because round, and enriched with buttons, or pearled like pilgrims staves, and frequently tipped or terminated with flower-de-luces; others blazon them, royal sceptres, placed in saltier, pale and fesse.

CARCHARIAS, in ichthyology. See SQUALUS.

CARCASSE, or CARCUSS, in the art of war, an iron-case, or hollow capacity, about the bigness of a bomb, of an oval figure, made of ribs of iron, filled with combustible matters, as meal-powder, saltpetre, sulphur, broken glass, shavings of horns, turpentine, tallow, *&c.*; the design of it is to be thrown out of a mortar to set houses on fire, and do other execution. It has two or three apertures through which the fire is to blaze.

CARCASSONE, a town of Languedoc, in France, situated on the river Ande, about twenty-five miles west of Narbonne: E. long. 2°, and N. lat. 43° 20′. It is a bishop's see.

CARCERES, in the ancient Circensian games, were inclosures, in the circus, wherein the horses were restrained till the signal was given for starting, when, by an admirable contrivance, they all at once flew open.

CARCINOMA. See CANKER.

CARD, among artificers, an instrument consisting of a block of wood, beset with sharp teeth, serving to arrange the hairs of wool, flax, hemp, and the like: there are different kinds of them, as hand-cards, stock-cards, *&c.*

CARDS, among gamesters, little pieces of fine thin pasteboard of an oblong figure, of several sizes, but most commonly in England three inches and an half long, and two and an half broad, on which are painted several points and figures.

The

The moulds and blocks for making cards, are exactly like thofe that were ufed for the firft books: they lay a fheet of wet or moift paper on the block, which is firft flightly done over with a fort of ink made with lamp-black diluted in water, and mixed with fome ftarch to give it a body. They afterwards rub it off with a round lift. The court-cards are coloured by means of feveral patterns, ftyled *ftane-files*. Thefe confift of papers cut through with a pen-knife, and in thefe apertures they apply feverally the various colours, as red, black, &c. Thefe patterns are painted with oil-colours, that the brufhes may not wear them out; and when the pattern is laid on the pafteboard, they flightly pafs over it a brufh full of colour, which, leaving it within the openings, forms the face or figure of the card.

Cards, upon fufficient fecurity, may be exported without payment of the ftamp-duty; but for every pack fold without the label of the ftamp-office, in England, there is a penalty of 10 l.

CARDAMINDUM, in botany. See TROPÆOLUM.

CARDAMINE, LADY'S SMOCK, in botany, a genus of the tetradynamia filiquofa clafs. The pod opens with a fpring, and the valves are revoluted: The ftigma is entire; and the calix gapes a little. There are fifteen fpecies, feven of which are natives of Britain, *viz.* the bellidifolia, or daify-leaved lady's-fmock; the petræa, or mountain lady's-fmock; the pratenfis, or common lady's-fmock; the amara, bitter creffes, or lady's-fmock; the impatiens, or impatient lady's-fmock; the parviflora, or fmall-flowered lady's-fmock; and the hirfuta, or hairy lady's-fmock.

CARDAMOM, in materia medica, the feeds of a fpecies of amomum. They are diftinguifhed into the leffer and greater. The greater cardamom is a dried fruit or pod containing two rows of fmall triangular feeds of a warm aromatic flavour. The leffer is about half the fize of the former, and the feeds are confiderably ftronger both in fmell and tafte. Hence this fort is the only one now ufed as a medicine. The feeds are warm, grateful, pungent, aromatic, and frequently employed as fuch in practice.

CARDIAC, an appellation given to fuch medicines as are fuppofed to preferve or increafe the ftrength of the heart.

CARDIACA, in botany. See LEONURUS.

CARDIALGIA, the HEART-BURN, in medicine, a diforder of the ftomach attended with anxiety, a naufea, and often a reaching or actual vomiting. See MEDICINE.

CARDIFF, a borough-town of Glamorganfhire, in fouth Wales, fituated on the river Tave, about two miles fouth-eaft of Landaff: W. long. 3° 20′, N. lat. 51° 30′. It fends only one member to parliament.

CARDIGAN, the capital of Cardiganfhire, near the mouth of the river Tivy and the Irifh channel, about thirty miles north of Pembroke: W. long. 4° 40, N. lat. 52° 15′. It gives the title of earl to the noble family of Brudenel, and fends only one member to parliament.

CARDINAL, in a general fenfe, an appellation given to things on account of their preheminence: thus we fay, cardinal virtues, &c.

CARDINAL SIGNS in the zodiac, are Aries, Libra, Cancer, and Capricorn.

CARDINAL, more particularly fignifies an ecclefiaftical prince in the Romifh church, being one who has a voice in the conclave at the election of a pope. The cardinals were originally nothing more than deacons, to whom was intrufted the care of diftributing the alms to the poor of the feveral quarters of Rome; and as they held affemblies of the poor in certain churches of their feveral diftricts, they took the title of thefe churches. They began to be called cardinals in the year 300, during the pontificate of St Sylvefter, by which appellation was meant the chief priefts of a parifh, and next in dignity to a bifhop. This office grew more confiderable afterwards, and by fmall degrees arrived at its prefent height, in which it is the reward of fuch as have ferved his holinefs well, even princes thinking it no diminution of their honour to become members of the college of cardinals.

The cardinals compofe the pope's council, and till the time of Urban VIII. were ftyled *moft illuftrious*; but by a decree of that pope in 1630, they had the title of *eminence* conferred upon them.

At the creation of a new cardinal, the pope performs the ceremony of fhutting and opening his mouth, which is done in a private confiftory. The fhutting his mouth, implies the depriving him of the liberty of giving his opinion in congregations; and the opening his mouth, which is performed fifteen days after, fignifies the taking off this reftraint. However, if the pope happens to die during the time a cardinal's mouth is fhut, he can neither give his voice in the election of a new pope, nor be himfelf advanced to that dignity.

The cardinals are divided into fix claffes or orders, confifting of fix bifhops, fifty priefts, and fourteen deacons, making in all feventy; which conftitute the facred college. The number of cardinal-bifhops has very feldom been changed, but that of priefts and deacons have varied at different times.

The privileges of the cardinals are very great: They have an abfolute power in the church during the vacancy of the holy fee: They have a right to elect the new pope, and are the only perfons on whom the choice can fall: Moft of the grand offices in the court of Rome are filled by cardinals. The drefs of a cardinal is a red foutanne, a rochet, a fhort purple mantle, and the red hat. When they are fent to the courts of princes, it is in quality of legates *a latere*; and when they are appointed governors of towns, their government is called by the name of legation.

CARDINAL is alfo a title given to fome bifhops, as thofe of Mentz and Milan, to the archbifhop of Bourges; and the abbot of Vendome calls himfelf cardinalis natus.

CARDINAL'S FLOWER. See RAPUNTIUM.

CARDIOID, in the higher geometry, an algebraical curve, fo called from its refemblance to a heart.

CARDIOSPERMUM, in botany, a genus of the octandria trigynia clafs. The calix has four leaves; there are four petals; an unequal four-leaved nectarium; and there are three inflated capfules. There are two fpecies, both natives of the Indies.

CARDIUM, in zoology, a genus of infects belonging to the order of vermes teftacea. The fhell confifts of two equal valves, and the fides are equal. There are 21 fpecies of this genus.

CARDONNA, a city of Catalonia, in Spain, fituated on a river of the fame name, about forty miles northweft of Barcelona: E. long. 1° 20′, N. lat. 41° 35′.

CARDUEL, a province of Georgia, in Afia, lying between the Cafpian and Euxine feas, the capital whereof is Teflis. It belongs partly to the Turks, and partly to the Perfians.

CARDUELIS, in ornithology, a fynonime of a fpecies of fringilla. See FRINGILLA.

CARDUUS, in botany, a genus of the fyngenefia polygamia æqualis clafs. The calix is ovated, and imbricated with fpinous fcales; and the receptacle is hairy. There are 26 fpecies, ten of which are natives of Britain, *viz.* the lanceolatus, or fpear-thiftle; the nutans, or mufk-thiftle; the acanthoides, or welted-thiftle; the crifpus, or thiftle upon-thiftle; the paluftris, or marfh-thiftle; the diffectus, or Englifh foft thiftle; the helenioides, or melancholy thiftle; the marianus, or milk-thiftle; and the acaulos, or dwarf carline-thiftle.

CAREENING, in the fea-language, the bringing a fhip to lie down on one fide, in order to trim and caulk the other fide.

A fhip is faid to be brought to the careen, when the moft of her lading being taken out, fhe is halled down on one fide by a fmall veffel as low as neceffary; and there kept by the weight of the ballaft, ordnance, *&c.* as well as by ropes, left her mafts fhould be ftrained too much; in order that her fides and bottom may be trimmed, feams caulked, or any thing that is faulty under water mended. Hence when a fhip lies on one fide when fhe fails, fhe is faid to fail on the careen.

CARELIA, in geography, a province of Finland, bounded by the province of Savolaxia on the north, and by the gulph of Finland on the fouth. It is fubject to Ruffia.

CARELSCROON, a port-town of the province of Gothland, in Sweden, fituated on the coaft of the Baltic: E. long. 15°, and N. lat. 56° 20′.

It is an excellent harbour, where the Swedes lay up their royal navy.

CARENTAN, a town of Normandy, in France, fituated at the mouth of a river of the fame name: W. long. 1° 15′, and N. lat. 49° 20′.

CARET, among grammarians, a character marked thus ^, fignifying that fomething is added on the margin, or interlined, which ought to have come in where the caret ftands.

CARETTA, in zoology, the trivial name of a fpecies of teftudo. See TESTUDO.

CAREX, in botany, a genus of the monœcia triandria clafs. The amentum of the male is imbricated; it has no corolla; and the calix confifts of one leaf. The amentum of the female is likewife imbricated; the corolla is wanting; and the calix confifts of one leaf; the nectarium is inflated and three-teethed; there are three ftigmata; and the feeds are triangular and contained within the nectarium. There are 37 fpecies, 26 of which are natives of Britain.

CARGADORS, a name which the Dutch give to thofe brokers, whofe bufinefs is to find freight for fhips outward bound, and to give notice to the merchants, who have commodities to fend by fea, of the fhips that are ready to fail, and of the places for which they are bound.

CARGAPOL, or KARGAPOL, the capital of a territory of the fame name, in the province of Dwina, in Mufcovy: E. long. 36°, and N. lat. 63°.

CARGO denotes all the merchandifes and effects which are laden on board a fhip.

Super-CARGO, a perfon employed by merchants to go a voyage, and overfee the cargo, and difpofe of it to the beft advantage.

CARIAMA, in ornithology, a fynonime of the palamedea. See PALAMEDEA.

CARIBBE-ISLANDS, a clufter of iflands, fituated in the Atlantic ocean, between 59° and 63°, W. long. and between 11° and 18° N. lat. They belong partly to the Britifh, and partly to the French, Dutch, *&c.*

CARIBBIANA, or CARIBIANA, the north eaft coaft of Terra-firma, in fouth America, otherwife called New-Andalufia. See ANDALUSIA.

CARICA, in botany, a genus of the diœcia decandria clafs. The male has hardly any calix; the corolla is bell-fhaped, and divided into five fegments; the filaments are inferted into the tube of the corolla, and are alternately fhorter. The calix of the female has five teeth; the corolla confifts of five petals; there are five ftigmata; and the berry is unilocular, and contains many feeds.

CARICATURA, in painting, denotes the concealment of real beauties, and the exaggeration of blemifhes, but ftill fo as to preferve a refemblance of the object.

CARICOUS, an epithet given to fuch tumours as refemble the figure of a fig. They are frequently found in the piles.

CARIES, in furgery, the corruption or mortification of a bone. See SURGERY.

CARIGNAN, a fortified town of Piedmont, fituated on the river Po, about feven miles fouth of Turin: E. long. 7° 25′, and N. lat. 44° 30′.

CARIGUE, or CARIGUEYA, in zoology, a fynonime of a fpecies of didelphis. See DIDELPHIS.

CARINTHIA, a duchy in the circle of Auftria, in Germany, bounded by the archbifhopric of Saltzburg on the north, and by Carniola and the dominions of Venice on the fouth. It is fubject to the houfe of Auftria.

CARIONOLA, a city of the province of Lavoro, in the

the kingdom of Naples, about twenty miles north of the city of Naples: E. long. 15°, and N. lat. 41° 20′. It is a bifhop's fee.

CARIPI, a kind of cavalry in the Turkifh army.

The caripi, to the number of about one thoufand, are not flaves, nor bred up in the feraglio, like the reft, but are generally Moors, or renegado Chriftians, who, having followed adventures, and being poor, and having their fortune to feek by their dexterity and courage, have arrived to the rank of horfe-guards to the grand fignior.

CARISBROOK-CASTLE, a caftle fituated in the middle of the ifle of Wight, where king Charles I. was imprifoned: W. long. 1° 30′, and N. lat. 50° 40′.

CARKE denotes the thirtieth part of a farplar of wool. See SARPLAR.

CARLINA, or CARLINE THISTLE, in botany, a genus of the fyngenefia polygamia æqualis clafs. The calix is radiated, with long coloured fcales. There are feven fpecies, only one of which, *viz.* the vulgaris, is a native of Britain. The roots are faid to be diaphoritic and alexipharmic.

CARLINE, or CAROLINE, a filver coin, current in the Neapolitan dominions, and worth about four-pence of our money.

CARLINGFORD, a port-town of Ireland, in the county of Lowth, and province of Leinfter, about twenty-two miles north of Drogheda: W. long. 6° 23′, and N. lat. 54° 5′.

CARLINGS, or CARLINES, in a fhip, two pieces of timber, lying fore and aft, along from beam to beam, whereon the ledges reft on which the planks of the fhip are faftened. All the carlings have their ends let into the beams culvertail-wife: They are directly over the keel, and ferve as a foundation for the whole body of the fhip.

CARLISLE, the capital city of Cumberland, fituated near the mouth of the river Eden, and the Solway frith: W. long. 2° 30′, and N. lat. 54° 45′.

It is a bifhop's fee.

CARLOCK, in commerce, a fort of ifing-glafs made with the fturgeon's bladder, imported from Archangel. The chief ufe of it is for clarifying wine; but it is alfo ufed by dyers. The beft carlock comes from Aftracan, where a great quantity of fturgeon is caught.

CARLOWITZ, a town of Sclavonia, fituated on the weft fide of the Danube, about thirty-five miles north-weft of Belgrade: E. long. 20° 45′, and N. lat. 45° 25′.

CARLSTADT, the capital of Croatia, a frontier province of Chriftendom againft the Turks: E. long. 16°, and N. lat. 45° 5′. It is fubject to the houfe of Auftria.

CARLSTADT is alfo the name of a town in the bifhopric of Wurtfburg, in the circle of Franconia in Germany, fituated on the river Maine, about fourteen miles north of Wurtfburg: E. long. 9° 50′. and N. lat. 50°.

CARMAGNIOL, a fortified town of Piedmont, fituated on the river Po, about ten miles fouth of Turin: E. long. 7° 30′, and N. lat. 44° 45′.

CARMELITES, or WHITE FRIERS, are an order of our lady of Mount Carmel, making one of the four orders of mendicants. They pretend to derive their original from the prophets Elijah and Elifha. Their original rules contained fixteen articles, one of which confined them to their cells, and enjoined them to employ themfelves day and night in prayer; another prohibited the brethren having any property; another enjoined fafting, from the feaft of the exaltation of the holy crofs till Eafter, excepting on Sundays; abftinence at all times from flefh, was enjoined by another article; one obliged them to manual labour; another impofed a ftrict filence on them, from vefpers till the tierce the next day: However, thefe conftitutions have been in fome refpects altered.

This order is fo much increafed, that it has at prefent thirty-eight provinces, befides the congregation of Mantua (in which there are fifty-four monafteries, under a vicar-general) and the congregation of bare-footed Carmelites in Italy and Spain, which have their peculiar generals.

If a monk of this order lie with a woman, he is prohibited faying mafs for three or four years, is declared infamous, and obliged to difcipline himfelf publicly once a week: If he is again guilty of the fame offence, his penance is doubled: And if a third time, he is expelled to order.

CARMENTALIA, feafts celebrated by the Romans, in honour of the prophetefs Carmenta, the mother of Evander.

They were folemnized twice in the month of January, *viz.* on the 11th and 15th.

CARMINATIVES, in pharmacy, medicines ufed in colics, or other flatulent diforders, to difpel the wind.

The four carminative flowers are thofe of camomile, melilot, motherwort, and dill; befides, angelica, fennel, lovage, anife, caraway, coriander, cummin, &c. all agree in their carminative qualities, and are therefore ufed in compofitions of that intention.

CARMINE, a powder of a very beautiful red colour, bordering upon purple, and ufed by painters in miniature; though but rarely, becaufe of its great price.

It is extracted from cochineal, by means of water, wherein chouan and antour have been infufed; fome add rocou, but this gives it too much of the oval caft. Others make carmine with brafil-wood, fernambouc, and leaf-gold, beat in a mortar, and fteeped in white-wine vinegar; the fcum arifing from this mixture, upon boiling, when dried, makes carmine; but this kind is vaftly inferior to the former: There is another carmine, made of brafil-wood and fernambouc, by a different preparation.

CARMONA, a town of Andalufia in Spain, about feventeen miles eaft of Sevil: W. long. 5° 35′, N. lat. 37° 20′.

CARNARVON, a borough-town of Carnarvonfhire, in north Wales, about five miles fouth-weft of Bangor: W. long. 4° 25′, and N. lat. 53° 20′. It gives the title of earl to the noble family of Bridges; and fends one member to parliament.

CARNATION, in botany. See CARYOPHYLLUS.

CARNATION-*colour*, among painters, is underſtood of all the parts of a picture, in general, which repreſent fleſh, or which are naked and without drapery.

In colouring for fleſh, there is ſo great a variety, that it is hard to lay down any general rules for inſtruction therein; neither are there any regarded by thoſe who have acquired a ſkill this way: The various colouring for carnations, may be eaſily produced, by taking more or leſs red, blue, yellow, or biſtre, whether for the firſt colouring, or for the finiſhing: The colour for women ſhould be bluiſh, for children a little red, both freſh and gay; and for the men it ſhould incline to yellow, eſpecially if they are old.

CARNELIAN, in natural hiſtory, a precious ſtone, of which there are three kinds, diſtinguiſhed by three colours, a red, a yellow, and a white. The red is very well known among us, and is found in roundiſh or oval maſſes, much like our common pebbles; and is generally met with between an inch and two or three inches in diameter: It is of a fine, compact, and cloſs texture, of a gloſſy ſurface; and, in the ſeveral ſpecimens, is of all the degrees of red, from the paleſt fleſh-colour to the deepeſt blood-red. It is generally free from ſpots, clouds, or variegations; but ſometimes it is veined very beautifully with an extremely pale red, or with white; the veins forming concentric circles, or other leſs regular figures, about a nucleus, in the manner of thoſe of agates. The pieces of carnelian which are all of one colour, and perfectly free from veins, are thoſe which our jewellers generally make uſe of for ſeals, though the variegated ones are much more beautiful. The carnelian is tolerably hard, and capable of a very good poliſh: It is not at all affected by acid menſtruums: The fire diveſts it of a part of its colour, and leaves it of a pale red; and a ſtrong and long continued heat will reduce it to a pale dirty gray.

The fineſt carnelians are thoſe of the Eaſt-Indies; but there are very beautiful ones found in the rivers of Sileſia and Bohemia; and we have ſome not deſpicable ones in England.

Though the ancients have recommended the carnelian as aſtringent, and attributed a number of fanciful virtues to it, we know no other uſe of the ſtone, than the cutting ſeals on it, to which purpoſe it is excellently adapted, as being not too hard for cutting, and yet hard enough not to be liable to accidents, to take a good poliſh, and to ſeparate eaſily from the wax.

CARNERO, in geography, a name given to that part of the gulf of Venice, which extends from the weſtern coaſt of Iſtria to the iſland of Groſſa and the coaſt of Morlachia.

CARNERO is likewiſe the name of the cape to the weſt of the mouth of the bay of Gibraltar.

CARNIOLA, a territory of Auſtria, in Germany, bounded by Carinthia and Stiria on the north, and by the dominions of Venice on the ſouth.

CARNIVAL, or CARNAVAL, a time of rejoicing, a ſeaſon of mirth, obſerved with great ſolemnity by the Italians, particularly at Venice, holding from twelfth-day till lent.

Feaſts, balls, operas, concerts of muſic, intrigues, marriages, *&c.* are chiefly held in carnival-time. The carnival begins at Venice the ſecond holiday in Chriſtmas: Then it is they begin to wear maſks, and open their play-houſes and gaming-houſes; the Place of St Mark is filled with mountebanks, jack-puddings, pedlars, whores, and ſuch like mob, who flock thither from all parts: There have been no leſs than ſeven ſovereign princes, and thirty thouſand foreigners here, to partake of theſe diverſions.

CAROB-*tree*. See CERATONIA.

CAROLINA, a province of N. America, belonging to Great Britain: It is ſituated, comprehending Georgia, between 75° and 86° W. long. and between 31° and 36° N. lat. and bounded by Virginia on the north, by the Atlantic ocean on the eaſt, by Spaniſh Florida on the ſouth, and by the Apalachian mountains on the weſt; or rather extends weſtward, without any limits. It is divided into three diſtinct governments, *viz.* North and South Carolina, and Georgia.

CAROLINE-*books*, the name of four books, compoſed by order of Charlemagne, to refute the ſecond council of Nice. Theſe books are couched in very harſh and ſevere terms, containing one hundred and twenty heads of accuſation againſt the council of Nice, and condemning the worſhip of images.

CAROLSTAT, a town of Gothland in Sweden, ſituated at the north end of the Wener-lake, about one hundred and forty miles weſt of Stokholm: E. long. 13° 30′, and N. lat. 59° 40′.

CAROLUS, an ancient Engliſh broad piece of gold, ſtruck under Charles I. its value has of late been at twenty-three ſhillings ſterling, though at the time it was coined, it is ſaid to have been rated at twenty ſhillings.

CAROLUS, a ſmall copper coin, with a little ſilver mixed with it, ſtruck under Charles VIII. of France.

The carolus was worth twelve deniers, when it ceaſed to be current.

Thoſe which are ſtill current in trade, in Lorrain, or in ſome neighbouring provinces, go under the name of French ſols.

CAROTID *arteries*, in anatomy. See p. 226.

CARP, in ichthyology, the Engliſh name of a ſpecies of cyprinus. See CYPRINUS.

CARPENTRY, the art of cutting, framing, and joining large pieces of wood, for the uſes of building. It is one of the arts ſubſervient to architecture, and is divided into houſe-carpentry and ſhip-carpentry: The firſt is employed in raiſing roofing, flooring of houſes, *&c.* and the ſecond in the building of ſhips, barges, *&c.* The rules in carpentry are much the ſame with thoſe of joinery; the only difference is, that carpentry is uſed in the larger coarſer work, and joinery in the ſmaller and curious. See JOINERY.

CARPET, a ſort of covering of ſtuff, or other materials, wrought with the needle or on a loom, which is part of the furniture of a houſe, and commonly ſpread over tables, or laid upon the floor.

Perſian

Perfian and Turkey carpets are thofe moft efteemed; though at Paris there is a manufactory after the manner of Perfia, where they make them little inferior, not to fay finer, than the true Perfian carpets. They are velvety, and perfectly imitate the carpets which come from the Levant. There are alfo carpets of Germany, fome of which are made of woollen ftuffs, as ferges, *&c.* and called fquare carpets: Others are made of wool alfo, but wrought with the needle, and pretty often embellifhed with filk; and laftly, there are carpets made of dog's hair. We have likewife carpets made in England, which are ufed either as floor-carpets, or to make chairs and other houfehold furniture: It is true, we are not arrived at the like perfection in this manufacture with our neighbours the French; but may not this be owing to the want of the like public encouragement?

CARPI, a town of the Veronefe in Italy, fituated on the river Adige, twenty four miles fouth-eaft of Verona: E. long 11° 40′, and N. lat. 45° 10′.

CARPINUS, the HORN-BEAN, in botany, a genus of the monœcia polyandria clafs. The calix of the male is bell-fhaped, and divided into five fegments; it has no corolla; and the ftamina are ten. The calix of the female has four teeth; there is no corolla; the ftyli are three; and the capfule has four valves, containing two feeds. There are but two fpecies, both natives of America.

CARPIO, in ichthyology, the trivial name of a fpecies of falmo and cyprinus. See SALMO, and CYPRINUS.

CARPOBALSAM, in the materia medica, the fruit of the tree which yields the true oriental balfam.

The caprobalfam is ufed in Egypt, according to Profper Alpinus, in all the intentions for which the balfam itfelf is applied: But the only ufe the Europeans make of it is in venice-treacle and mithridate, and in thefe not a great deal; for cubebs and juniper-berries are generally fubftituted in its place.

CARPOBOLUS, in botany. See LYCOPERDON.

CARPUS, the WRIST, in anatomy. See p. 179, 180.

CARR, among the ancients, a kind of throne mounted on wheels, and ufed in triumphs and other folemn occafions.

CARRIAGE, a vehicle ferving to convey perfons, goods, merchandifes, and other things from one place to another.

For the conftruction and mechanical principles of wheel-carriages, fee MECHANICS.

CARRIAGE *of a cannon*, the frame or timber-work on which it is mounted, ferving to point it for fhooting, or to carry it from one place to another. It is made of two planks of wood, commonly one half the length of the gun, called the cheeks, and joined by three wooden tranfoms, ftrengthened with three bolts of iron. It is mounted on two wheels; but on a march has two fore-wheels, with limbers added. The principal parts of a carriage are the cheeks, tranfums, bolts, plates, train, bands, bridge, bed, hooks, trunion-holes, and capfquare.

Block-CARRIAGE, a cart made on purpofe for carrying mortars and their beds from place to place.

Truck-CARRIAGE, two fhort planks of wood fupported on two axle-trees, having four trucks of folid wood for carrying mortars or guns upon battery, where their own carriages cannot go. They are drawn by men.

CARRICK, the moft foutherly divifion of the fhire of Air in Scotland.

CARRICK *on the Sure*, a town of Ireland, in the county of Tipperary, and province of Munfter, about fourteen miles north-weft of Waterford: W. long. 7° 24′, and N. lat. 52° 16′.

CARRICK-FERGUS, a town in the county of Antrim, and province of Ulfter, in Ireland, about eighty-five miles north of Dublin: W. long. 6° 15′, and N. lat. 54° 45′.

CARROT, in botany. See DAUCUS.

Candy-CARROT. See MYRRHIS.

Deadly-CARROT. See THAPSIA.

Mountain CARROT. See FOENICULUM.

CARROUSAL, a courfe of horfes and chariots, or a magnificent entertainment exhibited by princes on fome public rejoicing. It confifts in a cavalcade of feveral gentlemen richly dreffed and equipped, after the manner of ancient cavaliers divided into fquadrons, meeting in fome public place, and practifing jufts, tournaments, *&c.* The laft carroufals were in the reign of Lewis XIV.

CARS, or KARS, a city of Turcomania, or the greater Armenia, fituated on a river of the fame name: E. long. 44°, and N. lat. 41° 30′. It is fubject to the Turks.

CARSE, or CARSE *of Gowry*, the name of a diftrict of Perthfhire in Scotland, lying eaftward of Perth, on the northern bank of the Tay.

CART, a land-carriage with two wheels, drawn commonly with horfes, to carry heavy goods, *&c.* from one place to another. See MECHANICS.

CARTAMA, a town of Granada, in Spain, about ten miles north-weft of Malaga: W. long, 4° 30′, and N lat. 36° 40′.

CARTEL, an agreement made between two ftates for the exchange of their prifoners of war.

CARTEL fignifies alfo a letter of defiance, or a challenge, to decide a controverfy, either in a tournament, or in fingle combat. See DUEL.

CARTERET, a county of South Carolina, in North America.

CARTESIANS, a fect of philofophers, who adhere to the fyftem of Des Cartes, and founded on the two following principles; the one metaphyfical, the other phyfical: the metaphyfical one is, *I think, therefore I am*; the phyfical principal is, *That nothing exifts but fubftance*. Subftance he makes of two kinds; the one a fubftance that thinks, the other a fubftance extended; whence actual thought and actual extenfion are the effence of fubftance.

The effence of matter being thus fixed in extenfion, the Cartefians conclude, that there is no vacuum, nor any poffibility thereof in nature, but that the world is abfolutely full: mere fpace is precluded by this prin-

ciple,

ciple, in regard, extenfion being implied in the idea of fpace, matter is fo too.

Upon thefe principles, the Cartefians explain mechanically, and according to the laws of motion, how the world was formed, and whence the prefent appearances of nature do rife. They fuppofe, that matter was created of an indefinite extenfion, and divided into little fquare maffes, full of angles; that the Creator impreffed two motions on this matter; one whereby each part revolved round its centre, another whereby an affemblage, or fyftem, turned round a common centre; whence arofe as many different vortices as there were different maffes of matter, thus moving round common centres.

The confequences of this hypothefis, according to the Cartefians, will be, that the parts of matter in each vortex could not revolve among each other, without having their angles gradually broken, and that this continual friction of parts and angles produced three elements; the firft, an infinitely fine duft, formed of the angles broken off; the fecond, the fpheres remaining, after all the angular irregularities are thus removed: thefe two make the matter of Des Cartes's firft and fecond element; and thofe particles not yet rendered fmooth and fpherical, and which ftill retain fome of their angles, make the third element.

Now, according to the laws of motion, the fubtileft element muft take up the centre of each fyftem, being that which conftitutes the fun, the fixed ftars above, and the fire below; the fecond element, compofed of fpheres, makes the atmófphere, and all the matter between the earth and the fixed ftars, in fuch a manner as that the largeft fpheres are always next the circumference of the vortex or fyftem, and the fmalleft next its centre; the third element, or the hooked particles, is the matter that compofes the earth, all terreftrial bodies, comets, fpots in the fun, *&c.* Though both philofophers and divines have a juft plea againft this romantic fyftem, yet it muft be owned, that Des Cartes, by introducing geometry into phyfics, and accounting for natural phœnomena by the laws of mechanics, did infinite fervice to philofophy.

CARTHAGE, or New Carthage, the capital of Coftarica, a province of Mexico, in North America: W. long. 86°, and N. lat. 9° 44′.

CARTHAGENA, a large city, with one of the beft harbours in Spain, fituated in the province of Murcia, about twenty miles fouth of that city: W. long. 1° 5′, and N. lat. 37° 40′. It is a bifhop's fee.

New Carthagena, the capital of a province of the fame name, in South America, fituated on a kind of peninfula: W. long. 77°, and N. lat. 11°. It is one of the largeft and beft fortified towns in South America.

CARTHAMUS, or Bastard-saffron, in botany, a genus of the fyngenefia polygamia æqualis clafs. The calix is ovated, and imbricated with foliaceous fcales of an oval fhape. There are nine fpecies, none of them natives of Britain. The feeds are purgative; but operate flowly, and diforder the bowels.

CARTHUSIANS, a religious order, founded in the year 1080, by one Bruno. Their rules are very fevere. They are not to go out of their cells, except to church, without leave of their fuperior; nor fpeak to any perfon without leave. They muft not keep any portion of their meat or drink till next day; their beds are of ftraw, covered with a felt; their cloathing two hair-cloths, two cowls, two pair of hofe, and a cloke, all coarfe. In the refectory, they are to keep their eyes on the difh, their hands on the table, their attention on the reader, and their hearts fixed on God. Women are not allowed to come into their churches.

CARTHUSIAN-powder, the fame with kermes mineral. See Kermes.

CARTILAGE, in anatomy, a body approaching much to the nature of bones; but lubricous, flexible, and elaftic.

CARTMEL, a market-town of Lancafhire, about ten miles north-weft of Lancafter: W. long. 2° 40′, and N. lat. 54° 15′,

CARTON, or Cartoon, in painting, a defign drawn on ftrong paper, to be afterwards calked through, and transferred on the frefh plafter of a wall to be painted in frefco.

Carton is alfo ufed for a defign coloured, for working in mofaic, tapeftry, *&c.* The cartons at Hampton-court are defigns of Raphael Urbin, intended for tapeftry

CARTOUCHE, in architecture and fculpture, an ornament reprefenting a fcroll of paper. It is ufually a flat member, with wavings, to reprefent fome infcription, device, cypher, or ornament of armoury. They are, in architecture, much the fame as modillions; only thefe are fet under the cornice in wainfcotting, and thofe under the cornice at the eaves of a houfe.

Cartouche, in the military art, a cafe of wood, about three inches thick at the bottom, girt with marlin, holding about four hundred mufket-balls, befides fix or eight balls of iron, of a pound weight, to be fired out of a hobit, for the defence of a pafs, *&c.*

A cartouche is fometimes made of a globular form, and filled with a ball of a pound weight; and fometimes it is made for the guns, being of ball of half or quarter pound weight, according to the nature of the gun, tied in form of a bunch of grapes, on a tompion of wood, and coated over. Thefe were made in the room of partridge-fhot.

CARTRIDGE, in the military art, a cafe of pafteboard or parchment. holding the exact charge of a fire-arm. Thofe for mufkets, carabines, and piftols, hold both the powder and ball for the charge; and thofe of cannon and mortars are ufually in cafes of pafteboard or tin, fometimes of wood, half a foot long, adapted to the calibre of the piece.

Cartridge-box, a cafe of wood or turned iron, covered with leather, holding a dozen mufquet-cartridges. It is wore upon a belt, and hangs a little lower than the right pocket-hole.

CARVA, in botany. See Laurus.

CARUI, or Carvi, in botany. See Carum.

CARVING. See Sculpture.

CARUM, Caraway, in botany, a genus of the pentandria

tandria digynia clafs. The fruit is oblong and ftriated; the involucrum confifts of but one leaf; and the petals are carinated and emarginated. There is but one fpecies, *viz.* the caroi, a native of Britain. The feeds have an aromatic fmell and pungent tafte; and are frequently employed as a ftomachic and carminative in flatulent cafes.

CARUNCULA, in anatomy, a term denoting a little piece of flefh, and applied to feveral parts of the body, thus:

CARUNCULÆ MYRTIFORMES. See p. 276.

CARUS, in medicine, a fudden deprivation of fenfe and motion, affecting the whole body.

CARWAR, a town on the coaft of Malabar, in the Hither India, fixty miles fouth of Goa: E. long. 73°, and N. lat. 15°. Here our Eaft-India company have a factory, from whence they import pepper.

CARYATIDES, or CARAITES, in architecture. See p. 353.

CARYOCATACTES, in ornithology, the trivial name of a fpecies of corvus. See CORVUS.

CARYOCOSTINUM, or ELECTORIUM ET SCAMMONIO, in pharmacy, is compofed of the following ingredients: An ounce and a half of fcammony; of cloves and ginger, each fix drams; half a pound of honey; half a dram of effential oil of caraway-feeds; the fpices muft be ground together and mixed with the honey; then add the powdered fcammony, and afterwards the oil. This electuary is a warm brifk purgative.

CARYOPHYLLATA, in botany. See GEUM.

CARYOPHYLLUS, the PINK, in botany. See DIANTHUS.

CARYOPHYLLUS, the CLOVE-TREE, in botany, a genus of the polyandria monogynia clafs. The corolla has four petals; the calix confifts of four duplicated leaves; and the berry contains one feed. There is but one fpecies, *viz.* the aromaticus, a native of the Molucca iflands. The cloves are the flower-cups, have a ftrong agreeable aromatic fmell, and a bitterifh pungent tafte. The effential oil of cloves is an ingredient in many of our officinal compofitions.

CARYOTA, in botany, a genus of plants ranged under the palmæ bipennatifoliæ. The calix of the male is common; the corolla is divided into three parts; and the ftamina are numerous. The calix and corolla of the male are the fame with thofe of the female; there is but one piftillum; and the berry contains two feeds. There is but one fpecies, *viz.* the urens, a native of India.

CASAL, the capital of the duchy of Montferrat, in Italy, fituated on the river Po, forty-five miles eaft of Turin: E. long. 8° 35′, and N. lat. 45°.

CASAN, or KASAN, a province of Ruffia, lying between the province of Mofcow on the weft, and Siberia on the eaft.

CASCADE, a fteep fall of water from a higher into a lower place.

They are either natural, as that at Tivoli, *&c.* or artificial, as thofe of Verfailles, *&c.* and either falling with gentle defcent, as thofe of Sceaux; or in form of a buffet, as at Trianon; or down fteps, in form of a perron, as at St Clou; or from bafon to bafon, *&c.*

CASCAIS, a town of Eftremadura, in Portugal, fituated at the mouth of the river Tagus, feventeen miles eaft of Lifbon: W. long. 10° 15′, and N. lat. 38° 40′.

CASCARILLA, in botany. See CINCHONA.

CASE, among grammarians, implies the different inflexions or terminations of nouns, ferving to exprefs the different relations they bear to each other, and to the things they reprefent.

CASE, among printers, denotes a floping frame, divided into feveral compartments, each containing a number of types or letters of the fame kind. See PRINTING.

CASE *of crown-glafs* contains ufually twenty-four tables, each table being nearly circular, and about three feet fix inches diameter.

CASE *of Newcaftle glafs* contains thirty-five tables; of Normandy glafs twenty-five.

CASE-HARDENING, a method of preparing iron, fo as to render its outer furface hard, and capable of refifting any edged tool.

This is a leffer degree of fteel-making, and is practifed by baking, calcination, or cementation in an oven or other clofe veffel, ftratified with charcoal and powdered hoofs and horns of animals, fo as to exclude the air. See STEEL.

CASE-SHOT, in the military art, mufket-ball, ftones, old iron, *&c.* put into cafes, and fhot out of great guns.

CASERTA, a city of the province of Lavoro, in the kingdom of Naples, about fixteen miles north of the city of Naples: E. long. 15° 5′, and N. lat. 41° 10′. It is a bifhop's fee.

CASH-BOOK. See BOOK-KEEPING, p. 618.

CASHELL, or CASHILL, a city of the county of Tipperary, in Ireland, about eighty miles fouth-weft of Dublin: W. long. 7° 40′, and N. lat. 52° 16′. It is a bifhop's fee.

CASHEW-NUT, in botany. See ANACARDIUM.

CASIA, in botany. See OSYRIS.

CASK, a veffel of capacity, for preferving liquors of divers kinds; and alfo fometimes dry goods, as fugar, almonds, *&c.*

A cafk of fugar is a barrel of that commodity, containing from eight to eleven hundred weight. A cafk of almonds is about three hundred weight.

CASPIAN-SEA, a large fea, or lake of Afia, bounded by the province of Aftracan on the north, and by part of Perfia on the eaft, fouth, and weft. It is upwards of four hundred miles long from fouth to north, and three hundred miles broad from eaft to weft.

CASSANDRA, the fame with the lyra, or harp-fhell, a fpecies of dolium.

CASSANO, a fortrefs, in the Milanefe, in Italy, fituated on the river Adda, about twelve miles north-eaft of Milan: E. long. 10°, and N. lat. 45° 20′.

CASSEL, the capital of the landgravate of Heffe-caffel, is

in the circle of the Upper Rhine, in Germany, ſituated on the river Fulde: E. long. 2° 20′, and N. lat. 51° 20′.

CASSEL is alſo the name of a town in French Flanders, about fifteen miles ſouth of Dunkirk: E. long. 2° 30′, and N. lat. 50° 5′.

CASSIA, in botany, a genus of the decandria monogynia claſs. The calix conſiſts of five leaves; the petals are five; and the antheræ are roſtrated and barren; the pod is a legumen. There are 30 ſpecies, all natives of warm climates. The caſſia fiſtula is a native of Egypt, and the Eaſt Indies. The fruit is a cylindrical pod, the pulp of which is a gentle laxative medicine.

CASSIDA, in botany. See SCUTELLARIA.

CASSIDA, in zoology, a genus of inſects belonging to the order of coleoptera. The feelers are like threads, but thicker on the outſide; the elytra are marginated; and the head is hid under the thorax. There are 31 ſpecies of this inſect, diſtinguiſhed principally by differences in their colour.

CASSIMERE, the capital city of a province of the ſame name in the Hither India: E. long. 75°, and N. lat. 35°. It was once the capital of a kingdom, and is ſtill ſometimes the reſidence of the Mogul.

CASSINE, in botany, a genus of the pentandria trigynia claſs. The calix conſiſts of five parts or ſegments; the petals are five, and the berry contains three ſeeds. There are only two ſpecies, both natives of Æthiopia.

CASSIOPEIA, in aſtronomy, a conſtellation of the northern hemiſphere, ſituated oppoſite to the great bear, on the other ſide of the pole.

CASSIS, the HELMET SHELL. See MUREX.

CASSITERIA, in the hiſtory of foſſils, a genus of cryſtals, the figures of which are influenced by an admixture of ſome particles of tin.

The caſſiteria are of two kinds: the whitiſh pellucid caſſiterion, and the brown caſſiterion; the firſt is a tolerably bright and pellucid cryſtal, and ſeldom ſubject to the common blemiſhes of cryſtal: It is of a perfect and regular form, in the figure of a quadrilateral pyramid, and is found in Devonſhire and Cornwall principally. The brown caſſiterion is like the former in figure: It is of a very ſmooth and gloſſy ſurface, and is alſo found in great plenty in Devonſhire and Cornwall.

CASSOCK, or CASSULA, a kind of robe or gown, wore over the reſt of the habit, particularly by the clergy. The word caſſock comes from the French *caſaque*, an horſeman's coat.

CASSOWARY, in ornithology. See STRUTHIO.

CASSUMBAZAR, a town of India, in Aſia, ſituated on the river Ganges, in the province of Bengal: E. long. 37°, and N. lat. 24°.

CASSUMUNAR, in the materia medica, a root approaching to that of zedoary.

It is cardiac and ſudorific, and famous in nervous caſes: It is alſo an ingredient in many compoſitions, and is preſcribed in powders, boluſſes, and infuſions. Its doſe is from five to fifteen grains.

CASTANEA, in botany. See FAGUS.

CASTANOVITZ, a town of Croatia, ſituated on the river Unna, which divides Chriſtendom from Turky: E. long. 17° 20′, and N. lat. 45° 40′. It is ſubject to the houſe of Auſtria.

CASTEL-ARAGONESE, a fortreſs of Sardinia, ſituated on the north-weſt coaſt of that iſland: E. long. 8° 45′, and N. lat. 41°.

CASTEL-BAR, a town of Ireland, in the county of Mayo, and province of Connaught, about thirty-eight miles north of Gallway: W. long. 9° 24′, N. lat. 53° 25′.

CASTEL-BRANCHO, a city of the province of Beira, in Portugal, about ninety five miles north-eaſt of Liſbon: W. long. 8°, N. lat. 39° 35′.

CASTEL DE VIDE, a town of Alentejo, in Portugal, about twelve miles eaſt of Portalegre, and thirty-five weſt of Alcantara: W. long. 7° 40, N. lat. 39°.

CASTELLA, a town of the Mantuan, in Italy, about five miles north-eaſt of the city of Mantua: E. long. 11° 15′, N. lat. 45° 30′.

CASTELLAN, the name of a dignity or charge in Poland: The caſtellans are ſenators of the kingdom, but ſenators only of the lower claſs, who, in diets, ſit on low ſeats, behind the palatines, or great ſenators. They are a kind of lieutenants of provinces, and command a part of the palatinate under the palatine.

CASTELLANY, the territory belonging to any city or town, chiefly uſed in France and Flanders: Thus we ſay, the caſtellany of Liſle, Ypres, *&c.*

CASTIGLIONE, a fortified town in the duchy of Mantua, about twenty miles north-weſt of the city of Mantua: E. long. 11°, N. lat 45° 15′.

CASTILE, the name of two inland provinces of Spain, ſituated almoſt in the middle of that kingdom: The moſt ſoutherly one is called New Caſtile, and the other, towards the north, Old Caſtile; Madrid being the capital of the former, and Burges of the latter.

CASTILLAN, or CASTILLANE, a gold-coin, current in Spain, and worth fourteen rials and ſixteen deniers.

CASTILLAN is alſo a weight uſed in Spain for weighing gold. It is the hundredth part of a pound Spaniſh weight.

What they commonly call a weight of gold in Spain, is always underſtood of the caſtillan.

CASTILLARA, a town of the Mantuan, in Italy, ſituated ſix miles north-eaſt of the city of Mantua: E. long. 11° 25′, N. lat. 45° 20′.

CASTILLON, a town of Perigort, in the province of Guienne, in France, ſituated on the river Dordonne, ſixteen miles eaſt of Bourdeaux: W. long. 2° 40, N. lat. 44° 50′.

CASTLE, a fortreſs or place rendered defenceable, either by nature or art.

A caſtle is a fort, or little citadel. See CITADEL.

It frequently ſignifies with us the principal manſion of noblemen.

In the time of Henry II. there were no leſs than 1115 caſtles in England, each of which contained a manor.

CASTLE, in the ſea-language, is a part of the ſhip, of which there are two, the fore-caſtle, being the elevation

tion at the prow, or the uppermoſt deck towards the mizen, the place where the kitchens are. Hind-caſtle is the elevation which reigns on the ſtern, over the laſt deck, where the officers cabins and places of aſſembly are.

CASTLE-CAREY, a market town of Somerſetſhire, ſituated ten miles ſouth-eaſt of Wells: W. long. 2° 40′, N. lat. 51° 15′.

CASTLE-RISING, a borough-town of Norfolk, ſituated near the ſea coaſt, about thirty miles weſt of Norwich, and ſeven north of Lynn: E. long. 40′, N. lat. 52°. 46′. It ſends two members to parliament.

CASTLE-WORK, ſervice or labour done by inferior tenants, for the building and upholding of caſtles of defence, towards which ſome gave their perſonal aſſiſtance, and others paid their contributions. This was one of the three neceſſary charges to which all lands among our Saxon anceſtors were expreſsly ſubject.

CASTON, a market town of Norfolk, about eight miles north-weſt of Norwich: E. long. 1° 20′, N. lat. 52° 45′.

CASTOR, or BEAVER, in zoology, a genus of quadrupeds belonging to the order of glires. The fore-teeth of the upper jaw are truncated, and hollowed in a tranſverſe angular direction. The tops of the fore-teeth of the lower-jaw lie in a tranſverſe direction; and the tail is depreſſed. There are three ſpecies of caſtor, *viz.* 1. The fiber, with a plane ovated tail, is found on the banks of rivers in Europe, Aſia, and America. It is from the inguinal glands of this animal that the caſtor is obtained; it is contained in cods or pouches which reſemble a dog's teſticles.

Several writers have taken notice of the ingenuity of American beavers in making their houſes, of which we ſhall here give ſome account. The firſt thing they do when they are about to build, is to aſſemble in companies, ſometimes of two or three hundred together; then they chuſe a place where plenty of proviſions are to be had, and where all neceſſaries are to be found proper for their uſe. Their houſes are always in the water, and when they can find neither lake nor pond, they endeavour to ſupply that defect by ſtopping the current of a brook or ſmall river, by means of a dam. To this end they firſt cut down trees in the following manner: Three or four beavers will go to work about a large tree, and by continually gnawing of it with their teeth, they at laſt throw it down, and ſo contrive matters that it always falls towards the water, that they may have the leſs way to carry it, when they have divided it into pieces. After they have done this, they take each piece by itſelf, and roll it towards the water, where they intend to place it.

Theſe pieces are more or leſs thick and long, according to the nature and ſituation of the places where they are required. Sometimes they make uſe of the large trunks of trees, which they lay down flat; ſometimes the dam only conſiſts of branches as thick as one's thigh, which are ſupported by ſtakes interwoven with the branches of trees; and all the vacant places are filled up with a ſort of clay, in ſuch a manner, that no water can paſs through them. They prepare the clay with their paws or hands; and their tails ſerve inſtead of a carriage, as well as a trowel to lay on their clay.

The foundation of the dams are generally ten or twelve feet thick, and they leſſen gradually till they come to two or three. They always obſerve an exact proportion, inſomuch, that the moſt curious architects are not capable of performing their work more regularly. That ſide towards the current of the water is always ſloping, but the other is perpendicular.

The conſtruction of the houſes is altogether as wonderful; for they are generally built upon piles in ſmall lakes, which are formed by making of the dams. Sometimes they are on the bank of a river, or on the extremity of a point of land, which advances into the water. They are of a round or oval form, and the top of them is like a dome.

This deſcription of one of their houſes which was examined and meaſured, will perhaps give the reader more ſatisfaction than an account in general. It was about three parts ſurrounded with water, and the other part was joined to the land. It was round, with an oval dome at the top, and the height above the ſurface of the water, was eight feet. It was about forty feet in diameter, and one hundred and twenty in circumference, which perhaps may ſeem ſtrange, becauſe the proportion is geometrical; this however is fact, for it was meaſured ſeveral times. The part that joined to the bank was not made out of it, but was of the ſame materials with the reſt.

The bottom of the houſe was of earth, or ſoil, with pieces of wood laid in it, above three inches in circumference; then a parcel of poplar ſticks laid with one end in the houſe, and another ſlanting a long way under water; then a layer of earth again, and then poplar ſticks, which were repeated to the height of eighteen inches. From thence to the top of the houſe there was a mixture of earth, ſtones, and ſticks, curiouſly put together; and the whole was covered with ſods, that had long graſs growing thereon. The largeſt pieces of wood made uſe of near the top, were about three inches in diameter, and all the reſt was ſmall ſtuff, not above two or three fingers thick.

The outermoſt part of this houſe did not ſtand farther out in the creek than the edge of the ſhore; but that which brought the water almoſt round the houſe were the trenches, which were made by taking out the earth; theſe were nine feet in the broadeſt part, and eighteen feet in length. The creek at the front of the houſe was ſix and thirty feet broad, and ſeemed to be pretty deep. The houſe was ſo contrived as to be very ſolid, for there was no breaking into it without an ax; and in the froſty ſeaſon it was quite impenetrable. From this houſe there were ſeveral paths into the wood, through which they drew the ſticks and trees, which they made uſe of for food or building.

The wall of the houſe was two feet thick, and it was covered with ſmooth clay on the inſide in ſuch a manner that it would not admit the leaſt breath of air. Two thirds of the ſtructure was out of the water; and in the upper part, each beaver had his particular

ticular place, whereon leaves were ſtrewed to lie upon.

There never was any filth ſeen in any of theſe houſes, which are made like an oven in the inſide, with a paſſage for theſe animals to go and bathe in the water. One of theſe will generally lodge about eight or ten beavers, though ſometimes they have held thirty; but this is very uncommon.

Theſe creatures are never ſurpriſed by the froſt and ſnow; for they finiſh their work towards the end of September; and then they lay in proviſions for the winter. In the ſummer-time they live upon fruits, and the barks and leaves of trees; and they likewiſe catch ſmall fiſh, and particularly crabs or craw-fiſh. However, their winter-proviſion is the tender branches of trees, particularly poplar, of which they ſeem to be very fond. It is uſually ſaid, and upon pretty good authority, that theſe beavers make the walls of their houſes of a thickneſs in proportion to the ſeverity of the ſucceeding winter; which if true, theſe animals muſt be furniſhed with uncommon foreſight.

When there are great floods cauſed by the melting of the ſnow, which damage the houſes of the beavers, they then leave them, and ſhift for themſelves as well as they can; however, the females return as ſoon as the waters are abated; but the males keep the field till July, when they aſſemble again to repair the damage that has been done by the flood, either to their houſes or dams. When any of their houſes are demoliſhed by the hunters, they never repair them again, but build others quite new. Some authors have ſaid, that the beavers make ſeveral rooms in their houſes; but this upon examination has been found to be falſe.

In hunting the beavers, the ſavages ſometimes ſhoot them, always getting on the contrary ſide of the wind; for they are very ſhy, quick in hearing, and of a very keen ſcent. This is generally done when the beavers are at work, or on ſhore feeding on poplar bark. If they hear any noiſe when at work, they immediately jump into the water, and continue there ſome time; and when they riſe, it is at a diſtance from the place where they went in.

They ſometimes are taken with traps: theſe are nothing but poplar ſticks laid in a path near the water; which when the beaver begins to feed upon, they cauſe a large log of wood to fall upon their necks, which is put in motion by their moving of the ſticks, and conſequently requires an ingenious contrivance. The ſavages generally prefer this way of taking them, becauſe it does not damage their ſkins.

In the winter-time they break the ice in two places at a diſtance from the houſe, the one behind the other. Then they take away the broken ice with a kind of a racket, the better to ſee where to place their ſtakes. They faſten their nets to theſe, which have large meſhes, and ſometimes are eighteen or twenty yards in length. When theſe are fixed, they proceed to demoliſh the houſe, and turn a dog therein; which terrifying the beaver, he immediately leaves it, and takes to the water; after which, he is ſoon entangled by the net.

Mr Lawſon who was general ſurveyor of North Carolina, affirms, that beavers are very plenty in that country. He confirms what has been ſaid about their ingenuity in building of their dams and houſes, and obſerves, that their food is chiefly the bark of trees and ſhrubs; ſuch as that of the ſaſſafras, aſh, ſweet gum, and ſeveral others. He adds, that if they are taken young, they will become very tame; but then they will do a great deal of miſchief in the orchards, by breaking the trees. They will likewiſe block up the doors of the houſes in the night, with the ſticks and wood which they bring thither. He farther informs us, that it is certain death for them to eat any thing that is ſalt. The fleſh is looked upon as very delicate food.

2. The moſchatus, with a long, compreſſed, lanceolated tail, and palmated feet. It is the exotic water-rat of Cluſius, and is a native of Ruſſia.

3. The zibethicus, or muſk-rat, with a long, compreſſed, and lanceolated tail, and the toes of the feet ſeparate from each other. The follicles of the tail are ſaid to baniſh moths and other inſects from cloaths, *&c.* For this reaſon the inhabitants of Ruſſia and Canada ſew them into the folds of their cloaths, to keep off vermin and contagious diſeaſes.

CASTOR is alſo the name of a market-town of Lincolnſhire, twenty miles north-eaſt of Lincoln: W. long. 12′, and N. lat. 53° 30′.

CASTOREA, in botany. See DURANTA.

CASTOREUM, in the materia medica, a ſubſtance obtained from the inguinal glands of the caſtor. See CASTOR.

CASTRATION, in ſurgery, the operation of gelding.

It was prohibited by a decree of the ſenate of Rome under Hadrian; and the Cornelian law ſubjected the perſon who performed the operation, to the ſame penalties as the perſon on whom it was performed, although it was done with his conſent.

Caſtration is much in uſe in Aſia and Turkey, where it is practiſed upon the ſlaves, to prevent any commerce with their women. In Italy, caſtration is frequent from another motive, namely, to preſerve the voice for ſinging. It is ſometimes found neceſſary in chirurgical caſes, as in a ſarcocele and cancer of the teſticles. For the method of performing this operation, ſee SURGERY.

CASTRES, a city of Languedoc, in France, about thirty-five miles eaſt of Thoulouſe: E. long. 2°, and N. lat. 43° 40′. It is a biſhop's ſee.

CASTRO, the capital of the iſland of Chiloe, on the coaſt of Chili, in ſouth America: W. long. 82°, S. lat. 43°.

CASTRO is alſo the capital of a duchy of the ſame name in the pope's territories, in Italy, ſituated on the confines of Tuſcany: E. long. 12° 35′, N. lat. 42° 30′.

CASTRO is likewiſe a town in the territory of Otranto, in the kingdom of Naples, about ſeven miles ſouth of Otranto: E. long. 19° 25′, N. lat. 40° 8′.

CASTRO *marino*, a town in the province of Algarva, in Portugal, ſituated near the mouth of the river Guadiana, on the confines of Andaluſa: W. long. 8° 15′. N. lat. 37°.

CASUALTIES *of ſuperiority*, in Scots law, thoſe duties and emoluments which a ſuperior has right to demand out of his vaſſal's eſtate, over and beſides the conſtant yearly duties eſtabliſhed by the *reddendo* of his charter, upon certain caſual events. See SCOTS LAW, title, *Of the caſualties due to the ſuperior*.

CASUS *amiſſionis*, in Scots law. In actions of proving the tenor of obligations extinguiſhable by the debtor's retiring or cancelling them, it is neceſſary for the purſuer, before he is allowed a proof of the tenor, to condeſcend upon ſuch a *caſus amiſſionis*, or accident, by which the writing was deſtroyed, as ſhews it was loſt while in the creditor's poſſeſſion. See SCOTS LAW, title, *Actions*.

CAT, in zoology. See FELIS.

CAT-*mint*, in botany. See MENTHA.

CAT, or CAT-*head*, on ſhipboard, a ſhort piece of timber in a ſhip, lying aloft right over the hawſe, having at one end two ſhivers, wherein is reeved a rope, with a great iron-hook faſtened to it, called

CAT-*hook*. Its uſe is to trice up the anchor, from the hawſe to the top of the fore-caſtle.

CAT-*holes*, in a ſhip, are over the parts as right with the capſtan as they can be: Their uſe is to heave the ſhip a-ſtern, upon occaſion, by a cable, or hawſe, called ſtern-faſt. See STERN-FAST.

CAT *of the mountain*. See FELIS.

CAT-*ſilver*, in natural hiſtory. See MICÆ.

CATACAUSTIC *curves*, in the higher geometry, that ſpecies of cauſtic curves which are formed by reflexion. See FLUXIONS.

CATACRHESIS, in rhetoric, a trope which borrows the name of one thing to expreſs another. Thus Milton deſcribing Raphael's deſcent from the empyreal heaven to paradiſe, ſays,

"Down thither prone in flight
"He ſpeeds, and thro' the vaſt etherial ſky
"Sails between worlds and worlds."

CATACOMB, a grotto or ſubterraneous place for the burial of the dead.

The term is particularly uſed in Italy, for a vaſt aſſemblage of ſubterraneous ſepulchres, three leagues from Rome, in the *via Appia*, ſuppoſed to be the ſepulchres of the ancients. Others imagine theſe catacombs to be the cells wherein the primitive Chriſtians hid themſelves. Each catacomb is three feet broad, and eight or ten high, running in form of an alley or gallery, and communicating with one another.

CATAGMATICS, in pharmacy, remedies proper for curing a catagma or fracture.

CATALEPSY, in medicine. See MEDICINE.

CATALONIA, a province of Spain, bounded by the Pyrenean mountains which divide it from France, on the north; by the Mediterranean, on the eaſt and ſouth; and by the provinces of Aragon and Valencia, on the weſt.

CATAMENIA, in medicine. See MENSES.

CATAMITE, a boy kept for ſodomitical practices.

CATANANCHE, in botany, a genus of plants belonging to the ſyngeneſia polygamia æqualis claſs. The receptacle is paleaceous; the calix is imbricated; and the pappus has an awn, with a kind of cetaceous calix. There are three ſpecies, none of which are natives of Britain.

CATAPASM, among ancient phyſicians, ſignifies any dry medicine reduced to powder, in order to be uſed by way of inſpiration in the whole body, or any part of it.

CATAPHONICS, the ſcience which conſiders the properties of reflected ſounds.

CATAPHORA, in medicine, the ſame as coma. See COMA.

CATAPHRACTA, in antiquity, a kind of coat of mail, which covered the ſoldier from head to foot.

Hence, cataphracti were horſemen armed with the cataphracta, whoſe horſes, as Salluſt ſays, were covered with linen full of iron plates diſpoſed like feathers.

CATAPLASM, an external topical medicine, prepared of ingredients of different virtues, according to the intention of the phyſician. Hence there are different ſorts of cataplaſms with reſpect to the matter of which they conſiſt, as emollient, reſolvent, diſcutient, ſuppurative, corroborative, anodyne, and antiſeptic cataplaſms. They are commonly applied hot, or lukewarm, rolled up in linen cloths, which by means of the oils which are added preſerve heat for a conſiderable time; for which end alſo ſome, upon theſe, apply a ſwine's or ox's bladder, and ſometimes on the top of all apply an earthen tile.

CATAPULTA, in antiquity, a military engine contrived for the throwing of arrows, darts, and ſtones, upon the enemy.

Some of theſe engines were of ſuch force, that they would throw ſtones of an hundred weight. Joſephus takes notice of the ſurpriſing effects of theſe engines, and ſays, that the ſtones thrown out of them beat down the battlements, knocked off the angles of the towers, and would level a whole file of men, from one end to the other, were the phalanx never ſo deep.

CATARACT, in hydrography, a precipice in the channel of a river, cauſed by rocks, or other obſtacles, ſtopping the courſe of the ſtream, from whence the water falls with a greater noiſe and impetuoſity: Such are the cataracts of the Nile, the Danube, Rhine, and the famous one of Niagara in America.

CATARACT, in medicine and ſurgery, a diſorder of the humours in the eye, by which the pupilla, that ought to appear tranſparent and black, looks opaque, grey, blue, brown, &c. by which viſion is variouſly impeded, or totally deſtroyed. See MEDICINE, and SURGERY.

CATARO, the capital of a territory of the ſame name, in the Venetian Dalmatia, about twenty-five miles ſouth-eaſt of Raguſa: E. long. 19° 20′, N. lat. 42° 25′.

CATARACTES, in ornithology, the trivial name of a ſpecies of larus. See LARUS.

CATARRH, in medicine, a diſtillation or defluxion from the head upon the mouth and aſpera arteria, and

and through them upon the lungs. See MEDICINE.

CATASTASIS, in poetry, the third part of the ancient drama, being that wherein the intrigue, or action, ſet forth in the epitaſis, is ſupported and carried on, and heightened, till it be ripe for the unravelling in the cataſtrophe. Scaliger defines it, the full growth of the fable, while things are at a ſtand in that confuſion to which the poet has brought them.

CATASTROPHE, in dramatic poetry, the fourth and laſt part of the ancient drama, or that immediately ſucceeding the cataſtaſis: Or, according to others, the third only; the whole drama being divided into protaſis, epitaſis, and cataſtrophe; or, in the terms of Ariſtotle, prologue, epilogue, and exode. See EPIC and DRAMATIC *compoſitions*.

CATCH-*fly*, in botany. See LYCHNIS.

CATCH-POLE, a term uſed by way of reproach, for the bailiff's follower, or aſſiſtant.

CATCH-*word*, among printers, that placed at the bottom of each page, being always the firſt word of the following page.

CATECHETIC. Catechetic ſchools were buildings appointed for the office of the catechiſt, adjoining to the church, and called *catechumena*: Such was that in which Origen, and many other famous men, read catechetical lectures at Alexandria. See CATECHUMEN.

CATECHISM, the name of a ſmall book, deſigned for inſtructing children in the principles of religion. The church of Rome, the church of England, the preſbyterian church, *&c.* have all catechiſms containing and enforcing their peculiar opinions.

CATECHU, in the materia medica, the name of a troch conſiſting of Japan earth and gum arabic, each two ounces, and of ſugar of roſes ſixteen ounces, beat together, with a little water. It is recommended as a mild reſtringent, *&c.*

CATECHUMEN, a candidate for baptiſm, or one who prepares himſelf for the receiving thereof.

The catechumens, in church-hiſtory, were the loweſt order of Chriſtians in the primitive church. They had ſome title to the common name of Chriſtian, being a degree above pagans and heretics, though not conſummated by baptiſm. They were admitted to the ſtate of catechumens, by the impoſition of hands, and the ſign of the croſs. The children of believing parents were admitted catechumens, as ſoon as ever they were capable of inſtruction: But at what age thoſe of heathen parents might be admitted, is not ſo clear. As to the time of their continuance in this ſtate, there were no general rules fixed about it; but the practice varied according to the difference of times and places, and the readineſs and proficiency of the catechumens themſelves.

There were four orders or degrees of catechumens; the firſt were thoſe inſtructed privately without the church, and kept at a diſtance, for ſome time, from the privilege of entering the church, to make them the more eager and deſirous of it. The next degree were the *audientes*, ſo called from their being admitted to hear ſermons and the ſcriptures read in the church, but were not allowed to partake of the prayers. The third ſort of catechumens were the *genu flectentes*, ſo called, becauſe they received impoſition of hands kneeling. The fourth order was the *competentes & electi*, denoting the immediate candidates for baptiſm, or ſuch as were appointed to be baptized the next approaching feſtival, before which, ſtrict examination was made into their proficiency under the ſeveral ſtages of catechetical exerciſes.

After examination, they were exerciſed for twenty days together, and were obliged to faſting and confeſſion: Some days before baptiſm they went veiled; and it was cuſtomary to touch their ears, ſaying, *Ephatha*, i. e. be opened; as alſo, to anoint their eyes with clay; both ceremonies being in imitation of our Saviour's practice, and intended to ſhadow out to the catechumens their condition both before and after their admiſſion into the Chriſtian church.

CATEGORY, in logic, a ſeries or order of all the predicates or attributes contained under any genus.

The ſchool-philoſophers diſtribute all the objects of our thoughts and ideas into certain *genera* or claſſes, not ſo much, ſay they, to learn what they do not know, as to communicate a diſtinct notion of what they do know; and theſe claſſes the Greeks called categories, and the Latins predicaments.

Ariſtotle made ten categories, *viz.* quantity, quality, relation, action, paſſion, time, place, ſituation, and habit, which are uſually expreſſed by the following technical diſtich:

Arbor, ſex, ſervos, ardore, refrigerat, uſtos,
Ruri cras ſtabo, nec tunicatus ero.

CATENARIA, in the higher geometry, the name of a curve line formed by a rope hanging freely from two points of ſuſpenſion, whether the points be horizontal or not. See FLUXIONS.

CATERGI, the name of the public carriers in the grand Signior's dominions. In Europe, the merchant or traveller gives earneſt to the carrier; but the catergi in Turky give earneſt to the merchant and others, as a ſecurity that they will certainly carry their goods, or not ſet out with them.

CATERPILLAR, in zoology, the name of all winged inſects when in their reptile or worm-ſtate. See NATURAL HISTORY, *Of inſects*.

CATESBÆA, in botany, a genus of the tetrandria monogynia claſs. The corolla is long, monopetalous, and ſhaped like a tunnel; the ſtamina are within the faux; and the berry contains but one ſeed. There is but one ſpecies, *viz.* the ſpinoſa, a native of Providence.

CATHÆRETICS, in pharmacy, medicines of a cauſtic nature, ſerving to eat off proud fleſh.

CATHARTICS, in medicine, remedies which promote evacuation by ſtool.

CATHEDRAL, a church wherein is a biſhop's ſee or ſeat.

CATHETER, in ſurgery, a fiſtulous inſtrument, uſually made of ſilver, to be introduced into the bladder, in order to ſearch for the ſtone, or diſcharge the urine when ſuppreſſed. See SURGERY.

CATHETUS, in geometry, a line or radius falling perpendicularly

pendicularly on another line or furface: thus the catheti of a right-angled triangle are the two fides that include the right angle.

CATHETUS *of incidence*, in catoptrics, a right line drawn from a point of the object, perpendicular to the reflecting line.

CATHETUS *of reflection*, or *of the eye*, a right line drawn from the eye, perpendicular to the reflecting line.

CATHETUS *of obliquation*, a right line drawn perpendicular to the fpeculum, in the point of incidence or reflection.

CATHETUS, in architecture, a perpendicular line, fuppofed to pafs through the middle of a cylindrical body, as a balufter, column, *&c.*

CATHNESS, the moft northerly county of Scotland, having the Caledonian ocean on the north, eaft, and fouth-eaft, and the fhire of Sutherland on the fouth and weft. Its capital is Wick.

CATHOLIC, in a general fenfe, denotes any thing that is univerfal or general.

CATHOLIC CHURCH. The rife of herefies induced the primitive Chriftian church to affume to itfelf the appellation of catholic, being a characteriftic to diftinguifh it from all fects, who, though they had party-names, fometimes fheltered themfelves under the name of Chriftians.

The Romifh church diftinguifhes itfelf now by the name of catholic, in oppofition to all thofe who have feparated from her communion, and whom fhe confiders as only heretics and fchifmatics, and herfelf only as the true and Chriftian church. In the ftrict fenfe of the word, there is no catholic church in being, that is, no univerfal Chriftian communion.

CATHOLIC KING, a title which hath been hereditary to the kings of Spain, ever fince Alphonfus, who, having gained feveral victories over the Saracens, and re-eftablifhed the Chriftian faith in Spain, was honoured with the title of Catholic. Some fay it was in the time of Ferdinand and Ifabella.

CATHOLICON, in pharmacy, a kind of foft purgative electuary, fo called, as being fuppofed an univerfal purger of all humours.

CATOCHE, or CATOCHUS, in medicine, a difeafe, by which the patient is rendered, in an inftant, as immoveable as a ftatue, without either fenfe or motion, and continues in the fame pofture he was in at the moment he was feized. See MEDICINE.

CATODON, in ichthyology, the trivial name of a fpecies of phyfeter. See PHYSETER.

CATOPSIS, in medicine. See MYOPIA.

CATOPTRICS, that part of optics that treats of reflex vifion, and explains the laws and properties of reflection. See OPTICS.

CATULUS, in ichthyology. See SQUALUS.

CATUS-PARDUS, in zoology. See FELIS.

CATUS ZIBETHICUS. See CASTOR.

CATZENELLIBOGEN, a city of Heffe, fituated upon the Upper Rhine, in Germany, about fixteen miles north of Mentz: E. long. 7° 40′, N. lat. 50° 20′. It is the capital of a county of the fame name.

CAVALIER, in fortification, an elevation of earth of different fhapes, fituated ordinarily in the gorge of a baftion, bordered with a parapet, and cut into more or lefs embrafures, according to the capacity of the cavalier.

Cavaliers are a double defence for the faces of the oppofite baftion: they defend the ditch, break the befiegers galleries, command the traverfes in dry moats, fcowr the failliant angle of the counterfcarpe where the befiegers have their counter-batteries, and infilade the enemies trenches, or oblige them to multiply their parallels: they are likewife very ferviceable in defending the breach, and the retrenchments of the befieged, and can very much incommode the entrenchments which the enemy make, being lodged in the baftion.

CAVALIER, in the menage, one that underftands horfes, and is practifed in the art of riding them.

CAVALRY, a body of foldiers that charge on horfeback. They are divided into fquadrons, and encamp on the wings of the army.

CAVAN, the capital of a county of the fame name, in the province of Ulfter, in Ireland, fituated about fixty miles north-weft of Dublin: W. long. 7° 35′, and N. lat. 54°.

CAUCALIS, in botany, a genus of the pentandria digynia clafs. The corolla is radiated; the fruit is hairy, and the involucra are entire. There are fix fpecies, three of which are natives of Britain, *viz.* the arvenfis, or fmall corn-parfley; the anthrifcus, or hedge-parfley; and the leptophylla, or fine-leaved baftard parfley.

CAUCASUS, a vaft ridge of mountains, running from the Leffer Afia through the north of Perfia to the Eaft Indies; thefe acquire different names in the feveral countries through which they pafs.

CAUDIVERBERA, in zoology, the trivial name of a fpecies of lacerta. See LACERTA.

CAVEAR, CAVEER, or CAVIARY, the fpawn, or hard roes of fturgeon, made into fmall cakes, an inch thick, and of an hand's-breadth, falted, and dried in the fun. This fort of food is in great repute throughout Mufcovy, becaufe of their three lents, which they keep with a fuperftitious exactnefs; wherefore the Italians fettled at Mufcow, drive a very great trade in this commodity throughout that empire, becaufe there is a prodigious quantity of fturgeon taken at the mouth of the Wolga and of the other rivers which fall into the Cafpian fea. There is a pretty large quantity of this commodity confumed in Italy, and they are very well acquainted with it in France and England, where it is reckoned no defpicable difh.

The French and Italians get the cavear from Archangel, but they feldom get it at the firft hand, for they commonly buy it of the Englifh and Dutch.

CAVEAT, in law, a kind of procefs in the fpiritual courts, to ftop the proving of a will, the granting letters of adminiftration, *&c.* to the prejudice of another. It is alfo ufed to ftop the inftitution of a clerk to a benefice.

CAVEATING, in fencing, is the fhifting the fword from one fide of that of your adverfary to the other.

CAVEDO, in commerce, a Portuguefe long meafure, equal to $27\frac{354}{1000}$ Englifh inches.

CAVETTO, in architecture, a hollow member, or round concave moulding, containing a quadrant of a circle, and having a quite contrary effect to that of a quarter round: it is ufed as an ornament in cornices.

CAVEZON, in the menage, a fort of nofe-band, either of iron, leather, or wood, fometimes flat, and at other times hollow or twifted, clapt upon the nofe of a horfe, to wring it, and fo forward the fuppling and breaking of the horfe.

CAVIA-COBAYA, a fynonime of the mus porcellinus, or Guinea-pig. See MUS.

CAVILLON, a town of Provence in France, fituated on the river Durance, about fifteen miles fouth of Avignon: E. long. 5°, and N. lat. 43° 50'. It is a bifhop's fee, and fubject to the pope.

CAUKING, or CAULKING *of a fhip*, is driving oakum, or the like, into all the feams of the planks of a fhip, to prevent leaking, and keep out the water.

CAULKING-IRONS, are iron chiffels for that purpofe. Some of thefe irons are broad, fome round, and others grooved. After the feams are ftopped with oakum, it is done over with a mixture of tallow, pitch, and tar, as low as the fhip draws water.

CAUL, in anatomy. See p. 266. col. 2.

CAULIFLOWERS, in gardening, a much efteemed fpecies of cabbage.

Cauliflowers have of late years been fo much improved in Britain, as to exceed in goodnefs and magnitude any produced in moft parts of Europe; and, by the fkill of the gardener, are continued for feveral months together, but the moft common feafon for them is in May, June, and July.

CAULIS, in botany. See p. 641. col. 2. and Plate LVII. fig. 148.

CAUSALTY, among metaphyficians, the action or power of a caufe in producing its effect.

CAUSALTY, among miners, denotes the lighter, fulphureous, earthy parts of ores, carried off in the operation of wafhing.

This, in the mines, they throw in heaps upon banks, which, in fix or feven years, they find it worth their while to work over again.

CAUSE, that from whence any thing proceeds, or by virtue of which any thing is done: it ftands oppofed to effect. We get the ideas of caufe and effect from our obfervation of the viciffitude of things, while we perceive fome qualities or fubftances begin to exift, and that they receive their exiftence from the due application and operation of other beings. That which produces, is the caufe; and that which is produced, the effect: thus, fluidity in wax is the effect of a certain degree of heat, which we obferve to be conftantly produced by the application of fuch heat.

Firft CAUSE, that which acts of itfelf, and of its own proper power or virtue: God is the only firft caufe in this fenfe.

Second CAUSES are thofe which derive the power and faculty of action from a firft caufe.

Efficient CAUSES are the agents employed in the production of any thing.

Material CAUSES, the fubjects whereon the agents work; or the materials whereof the thing is produced.

Final CAUSES are the motives inducing an agent to act; or the defign and purpofe for which the thing was done.

Phyfical CAUSE, that which produces a fenfible corporeal effect; as the fun is the phyfical caufe of light.

Moral CAUSE, that which produces a real effect, but in things immaterial; as repentance is the caufe of forgivenefs. A moral caufe is alfo defined, that which determines us, though not neceffarily, to do, or not to do, any thing; as advice, intreaties, commands, menaces, *&c.*

It is to be obferved, that, in this fenfe, a moral caufe is only applicable to a free intelligent agent: it is alfo obfervable, that the latter notion of a phyfical as well as a moral caufe is the moft juft, clear, and diftinct.

CAUSE, among civilians, the fame with action. See ACTION.

CAUSTICS, in phyfic, an appellation given to medicines of fo hot and fiery a nature, that, being applied, confume, and, as it were, burn the texture of the parts, like hot iron.

Cauftics are generally divided into four forts, the common ftronger cauftic, the common milder cauftic, the antimonial cauftic, and the lunar cauftic.

The ftronger cauftic is prepared by boiling to a fourth part any quantity of the lees of almond-foap, adding lime that has been kept in a veffel pretty clofe ftopt for feveral months; the lime is to be added till all the liquor is abforbed, and the whole reduced to a pafte, which is to be kept in a veffel well ftopt.

The common milder cauftic is prepared by taking equal parts of foft foap and frefh quick-lime, and mixing them at the time of ufing.

The antimonial cauftic is prepared thus: Take of antimony one pound, of corrofive fublimate two pounds; and being reduced feparately into powder, mix them well, and diftill them in a retort with a wide neck, in a gentle heat of fand; let what afcends into the neck of the retort be expofed to the air, that it may run into a liquor.

The method of preparing the lunar cauftic is as follows: Diffolve pure filver by a fand-heat, in about twice its weight of aqua-fortis; then dry away the humidity with a gentle fire, afterwards melt it in a crucible, that it may be poured into proper moulds, carefully avoiding over-much heat, left the matter fhould grow too thick.

CAUSTIC CURVE, in the higher geometry, a curve formed by the concourfe or coincidence of the rays of light reflected from fome other curve.

CAUSTIC GLASSES. See BURNING-GLASSES.

CAUSTICUM ANTIMONIALE, in the London Difpenfatory, the fame with the oil of antimony.

CAUSUS, or BURNING-FEVER, a fpecies of continual fever, accompanied with a remarkable inflammation of the blood.

CAUTERIZATION, the application of cauteries to any part of the body.

CAUTERY, in ſurgery, a medicine for burning, eating, or corroding any ſolid part of the body.

Cauteries are diſtinguiſhed into two claſſes, actual and potential: by actual cauteries, are meant red hot inſtruments, uſually of iron, and by potential cauteries are underſtood certain kinds of corroding medicines. See MEDICINE, and SURGERY.

CAUTION, in the civil and Scots law, denotes much the ſame with what, in the law of England, is called bail. See BAIL.

CAUTIONER, in Scots law, that perſon who becomes bound for another to the performance of any deed or obligation. As to the diifferent kinds and effects of cautionry, ſee SCOTS LAW, title, *Obligations ariſing from conſent.*

CAXA, a little coin made of lead, mixed with ſome ſcoria of copper, ſtruck in China, but current chiefly at Bantam in the iſland of Java, and ſome of the neighbouring iſlands.

The caxas are of two kinds, great and ſmall. Of the ſmall, 300,000 are equal to fifty-ſix livres five ſols French money; and of the great, 6000 are equal to four ſhillings and ſixpence ſterling.

CAXAMALCA, the name of a town and diſtrict of Peru, in South America, where there was a moſt ſumptuous palace belonging to the Yncas, and a magnificent temple dedicated to the ſun. It was at Caxamalca that Pizarro put to death Athualpha, their laſt king.

CAY, in zoology, a ſynonime of the ſimia midas. See SIMIA.

CAZEROM, or CAZERON, a city of Perſia, the capital of the province of Kurch Schabour, ſituated in 70° E. long. and 29° 15′ N. lat.

CAZIMIR, a town of Poland, in the palatinate of Lublin.

CEANOTHUS, in botany, a genus of the pentandria monogynia claſs. The petals are vaulted; and the berry is dry, having three cells, containing each one ſeed. There are three ſpecies, none of them natives of Britain.

CECROPIA, in botany, a genus of the diœcia diandria claſs. The ſpatha of the male is caducous; the amenta are imbricated with helmet-ſhaped ſcales; and the corolla is wanting. The germina of the female are imbricated; it has but one ſtylus; the ſtigma is lacerated; and the berry contains but one ſeed. There is one ſpecies, *viz.* the peltata, a native of Jamaica.

CEDAR, in botany, the Engliſh name of a ſpecies of juniperus. See JUNIPERUS.

CEDRELA, in botany, a genus of the pentandria monogynia claſs. The calix is bell-ſhaped, and divided into three ſegments; the corolla is ſhaped like a funnel, and has five petals inſerted into the baſe of the receptacle; the capſule is lignous, and has five cells and five valves; the ſeeds are imbricated on the back part, and have membranaceous edges. There is but one ſpecies, *viz.* the odorata, a native of America.

CEDRUS, in botany. See JUNIPERUS, and PINUS.

CELANDINE, in botany. See CHELIDONIUM.

CELASTRUS, in botany, a genus of the pentandria monogynia claſs. The corolla conſiſts of five open petals; the capſule is triangular, and has three cells; and the ſeeds have a calyptra. There are five ſpecies, none of them natives of Britain.

CELERES, in Roman antiquity, a regiment of body-guards, belonging to the Roman kings, eſtabliſhed by Romulus, and compoſed of 300 young men, choſen out of the moſt illuſtrious Roman families, and approved by the ſuffrages of the curiæ of the people, each of which furniſhed ten.

CELERI, in botany, the Engliſh name of the apium graveolens, or celery, which is cultivated in our gardens as a pot-herb.

CELERITY, in mechanics, the ſwiftneſs of any body in motion.

It is alſo defined to be an affection of motion, by which any moveable body runs through a given ſpace in a given time. See MECHANICS.

CELESTINS, in church-hiſtory, a religious order of Chriſtians, reformed from the Bernardins by pope Celeſtin V. Their rules are divided into three parts; the firſt, of the provincial chapters, and the elections of ſuperiors; the ſecond contains the regular obſervances; and the third, the viſitation and correction of the monks.

The Celeſtins riſe two hours after midnight to ſay matins: they eat no fleſh at any time, except when they are ſick: they faſt every Wedneſday and Friday to the feaſt of the exaltation of the holy croſs; and from that feaſt to Eaſter, every day.

CELIBACY, the ſtate of unmarried perſons, to which, according to the doctrine, or at leaſt the diſcipline, of the church of Rome, the clergy are obliged.

That celibacy has no pretence of divine or apoſtolical inſtitution, ſeems no difficult point to prove: whence it is, at firſt, hard to conceive from what motive the court of Rome perſiſted ſo very obſtinately to impoſe this inſtitution on the clergy. But we are to obſerve, that this was a leading ſtep to the execution of the project formed of making the clergy independent of princes, and rendering them a ſeparate body, to be governed by their own laws. In effect, while prieſts had children, it was very difficult to prevent their dependence upon princes, whoſe favours have ſuch an influence on private men; but having no family, they were more at liberty to adhere to the pope.

CELOSIA, in botany, a genus of the pentandria monogynia claſs. The calix has three leaves; the ſtamina are joined to the baſe of a plaited nectarium; and the capſule opens horizontally. There are eight ſpecies, none of them natives of Britain.

CELSIA, in botany, a genus of the didynamia angioſpermia claſs. The calix is divided into five ſegments; the corolla is rotated; the filaments are barbed; and the capſule is bilocular. There is but one ſpecies, *viz.* the orientalis, a native of Greece.

CELTIS, in botany, a genus of the polygamia monœcia claſs. The calix of the hermaphrodite is divided into five ſegments; it has no corolla; there are five ſtamina,

ſtamina, and two ſtyli; the drupa contains but one ſeed. The calix of the male is divided into ſix ſegments; it has no corolla; and the ſtamina are ſix. The ſpecies are three, none of them natives of Britain.

CEMENT, or CÆMENT. See CÆMENT.

CEMENTATION. See CÆMENTATION.

CEMETERY. See COEMETERY.

CENADA, a town of the Venetian territories in Italy, ſituated about thirty-two miles north of Padua: E. long. 12° 40′, and N. lat. 46° 5′.

CENCHRAMIDEA, in botany. See CLUSIA.

CENCHRIS, in zoology, a ſynonime of the boa conſtrictor. See BOA.

CENCHRUS, in botany, a genus of the polygamia monœcia claſs. The involucrum is laciniated, and incloſes two flowers; the calix is a two flowered gluma, one of the flowers being a male, and the other a female. The corolla of the hermaphrodite is a blunt gluma; the ſtamina are three; and the ſtylus is bifid; there is but one ſeed. The corolla of the male is likewiſe an obtuſe gluma; and there are three ſtamina. The ſpecies are ſix, none of them natives of Britain.

CENCONTLTAOLLI, in ornithology. See TURDUS.

CENOBITE, or COENOBITE. See COENOBITE.

CENOTAPH, in antiquity, a monument erected in honour of the dead, but not containing any of their remains. Of theſe there were two ſorts; one erected for ſuch perſons as had been honoured with funeral rites in another place; and the ſecond ſort, for thoſe that had never obtained a juſt funeral.

The ſign whereby honorary ſepulchres were diſtinguiſhed from others, was commonly the wreck of a ſhip, to denote the deceaſe of the perſon in ſome foreign country.

CENSER, a ſacred inſtrument made uſe of in the religious rites of the ancients. It was a vaſe, containing incenſe to be uſed in ſacrificing to the gods. Cenſers were likewiſe in uſe among the Jews, as we find in 1 Kings vii. 50. The cenſer is alſo uſed in Romiſh churches.

CENSOR, in Roman antiquity, a magiſtrate, whoſe buſineſs it was to reform the manners, and to value the eſtates of the people.

There were two cenſors firſt created in the 311th year of Rome, upon the ſenate's obſerving that the conſuls were generally ſo much taken up in military actions as to have no leiſure to attend to private affairs. At firſt they were choſen out of the ſenate, but after the plebeians had got the conſulate open to them, they ſoon arrived at the cenſorſhip.

After the cenſors were elected in the comitia centurialia, they proceeded to the capitol, where they took an oath not to manage either by favour or diſaffection, but to act equitably and impartially through the whole courſe of their adminiſtration: and, notwithſtanding their great authority, they were obliged to give an account of their management to the tribunes and *ædiles curules*. In proceſs of time, the dignity of this office dwindled very much; under the emperors it ſunk to nothing, as their majeſties engroſſed all the branches of that juriſdiction. The republic of Venice has at this day a cenſor of manners of their people, whoſe office laſts ſix months.

CENSORS *of books*, are a body of doctors or others eſtabliſhed in divers countries, to examine all books before they go to the preſs, and to ſee they contain nothing contrary to faith and good manners.

At Paris, the faculty of theology claim this privilege, as granted to them by the pope; but in 1624, new commiſſions of four doctors were created, by letters-patent, the ſole cenſors of all books, and anſwer able for every thing contained therein.

In England, we had formerly an officer of this kind, under the title of Licenſer of the preſs; but, ſince the revolution, our preſs has been laid under no ſuch reſtraint.

CENSURE, a judgment which condemns ſome book, perſon, or action, or more particularly a reprimand from a ſuperior. Eccleſiaſtical cenſures, are penalties by which, for ſome remarkable miſbehaviour, Chriſtians are deprived of the communion of the church, or prohibited to execute the ſacerdotal office.

CENSUS, in Roman antiquity, an authentic declaration made before the cenſors, by the ſeveral ſubjects of the empire, of their reſpective names and places of abode. This declaration was regiſtered by the cenſors, and contained an enumeration, in writing, of all the eſtates, lands, and inheritances they poſſeſſed; their quantity, quality, place, wives, children, domeſtics, tenants, ſlaves.

The cenſus was inſtituted by Servius Tullius, and was held every five years. It was of great ſervice to the republic, becauſe, by means of it, they diſcovered the number of citizens capable of bearing arms, and the money they could afford for the expence of a war. It went through all ranks of people, though under different names: that of the common people was called *cenſus*; that of the knights, *cenſus, recenſio, recognitio*; that of the ſenators, *lectio, relectio*.

The cenſus which intitled one to the dignity of a knight, was 400,000 ſeſterces: that of a ſenator, was double that ſum.

In the Voconian law, cenſus is uſed for a man, whoſe eſtate in the cenſor's books is valued at 100,000 ſeſterces.

CENTAUR, in ancient poetry, denotes a fabulous kind of animal, half man, half horſe.

The Theſſalians, who firſt taught the art of breaking horſes, appearing on horſeback to make only one body with the animal on which they rode, gave riſe to the fiction of the hippocentaur.

CENTAUREA, in botany, a genus of the ſyngeneſia polygamia fruſtranea claſs. The receptacle is briſtly; the pappus is ſimple; the rays of the corolla are tunnel-ſhaped, long, and irregular. There are 61 ſpecies, five of which are natives of Britain, *viz.* the cyanus, or blue-bottle; the ſcabioſa, or great knapweed; the jacea, or common knapweed; the calcitrapa, or ſtar-thiſtle; and the ſolſtitialis, or St Barnaby's thiſtle.

CENTAURY. See CHELIDONIUM.

CENTER *of gravity*, in mechanics, that point about which all the parts of a body do, in any ſituation, exactly balance each other. See MECHANICS.

CENTER *of motion*, that point which remains at reſt, while all the other parts of a body move about it. See MECHANICS.

CENTESIMATION, a milder kind of military puniſhment, in caſes of deſertion, mutiny, and the like, when only every hundredth man is executed.

CENTIPES, in zoology. See SCOLOPENDRA.

CENTONARII, in antiquity, certain officers of the Roman army, who provided tents and other ſtuff, called centones, made uſe of to quench the fire which the enemy's engines threw into the camp.

Theſe centonarii kept with the carpenters and other officers of the artillery.

CENTRAL FORCES, the powers which cauſe a moving body to tend towards, or recede from the centre of motion. See MECHANICS.

CENTRAL RULE, a rule diſcovered by Mr Thomas Baker, whereby to find the centre of a circle deſigned to cut the parabola in as many points, as an equation to be conſtructed hath real roots. Its principal uſe is in the conſtruction of equations, and he has applied it with good ſucceſs as far as biquadratics.

The central rule is chiefly founded on this property of the parabola, that if a line be inſcribed in that curve perpendicular to any diameter, a rectangle formed of the ſegments of the inſcript, is equal to the rectangle of the intercepted diameter and parameter of the axis.

The central rule has the advantage over Cartes and De Latere's methods of conſtructing equations, in that both theſe are ſubject to the trouble of preparing the equation, by taking away the ſecond term.

CENTRIFUGAL FORCE, that force by which all bodies that move round any other body in a curve, endeavour to fly off from the axis of their motion in a tangent to the periphery of the curve, and that in every point of it. See MECHANICS.

CENTRINA, in ichthyology, the trivial name of a ſpecies of ſqualus. See SQUALUS.

CENTRIPETAL FORCE, that force by which a body is every where impelled, or any how tends towards ſome point as a centre. See MECHANICS.

CENTRISCUS, in ichthyology, a genus belonging to the order of amphibia nantes. The head gradually ends in a narrow ſnout; the aperture is broad and flat; the belly is carinated; and the belly-fins are united. There are two ſpecies, *viz.* 1. The ſcutatus has its back covered with a ſmooth bony ſhell, which ends in a ſharp ſpine, under which is the tail; but the back-fins are between the tail and the ſpine. It is a native of the Eaſt Indies. 2. The ſcolopax has a rough ſcabrous body, and a ſtrait extended tail. It has two belly-fins, with four rays in each, and has no teeth. It is found in the Mediterranean.

CENTUMVIRI, in Roman antiquity, judges appointed to decide common cauſes among the people: they were choſen three out of each tribe; and though five more than an hundred, were nevertheleſs called centumviri, from the round number centum, an hundred.

CENTUNCULUS, in botany, a genus of the tetrandria monogynia claſs. The calix conſiſts of four ſegments; the corolla has four diviſions, and open; the ſtamina are ſhort; and the capſule has but one cell. There is only one ſpecies, *viz.* the minimus, or baſtard pimpernel, a native of Britain.

CENTURION, among the Romans, an officer in the infantry, who commanded a century, or an hundred men.

The centurions held the firſt rank in the firſt cohort of a legion, and two of them the place of the two firſt haſtati or pike-men: the firſt among the principes was alſo a centurion.

The centurion primipilus was the chief of the centurions: he was not under the command of any tribune, as all the reſt were; he had four centuries under his direction, and guarded the ſtandard and the eagle of the legion.

CENTURY, in a general ſenſe, any thing divided into or conſiſting of an hundred parts.

The Roman people, when they were aſſembled for the electing of magiſtrates, enacting of laws, or deliberating upon any public affair, were always divided into centuries, and voted by centuries, in order that their ſuffrages might be the more eaſily collected; whence theſe aſſemblies were called *comitia centuriata*. The Roman cohorts were alſo divided into centuries. See CENTURION and COHORT.

CENTURY, in chronology, the ſpace of one hundred years.

This method of computing by centuries is generally obſerved in church-hiſtory, commencing from the time of our Saviour's incarnation; in which ſenſe we ſay the firſt century, the ſecond century, *&c.*

CENTURIES *of Magdeburg*, a famous eccleſiaſtical hiſtory, ranged into thirteen centuries, carried down to the year 1298, compiled by ſeveral hundred Proteſtants of Magdeburg, the chief of whom was Matthias Flacius Illyricus.

CENTUSSIS, in Roman antiquity, a coin containing an hundred aſſes.

CEPA, in botany, the trivial name of a ſpecies of allium. See ALLIUM.

CEPÆA, in botany. See SEDUM.

CEPHALANTHUS, in botany, a genus of the tetrandria monogynia claſs. It has no common calix; the proper calix is tunnel-ſhaped; the receptacle is globular, and naked; and the ſeeds are downy. There is but one ſpecies, *viz.* the occidentalis, a native of America.

CEPHALIC, in a general meaning, ſignifies any thing belonging to the head.

CEPHALIC *medicines* are remedies for diſorders of the head.

CEPHALIC *vein*, in anatomy. See p. 241.

CEPHALONIA, the capital of an iſland of the ſame name, ſituated in the Mediterranean, near the coaſt of

of Epirus, and subject to the Venetians: E. long. 21°, and N. lat. 38° 30'.

CEPHALOPHARYNGÆI, in anatomy. See p. 302.

CEPHALUS, in ichthyology, the trivial name of a species of mugil. See MUGIL.

CEPHEUS, in astronomy, a constellation of the northern hemisphere.

CEPHUS, in ornithology, a synonime of a species of larus. See LARUS.

CERAM, an island in the Indian ocean, between the Molucca islands on the north, and those of Amboyna and Banda on the south, lying between 126° and 129° E. long. and in 3° S. lat.

It is about one hundred and fifty miles long, and sixty broad; and here the Dutch have a fortress, which keeps the natives in subjection.

CERAMBYX, in zoology, a genus of insects of the beetle kind, belonging to the order of insecta coleoptera. The antennæ are long and small; the breast is spinous or gibbous; and the elytra are linear. There are no less than 83 species enumerated by Linnæus, principally distinguished by the figure of the breast.

CERASTES, in zoology, the trivial name of a species of coluber; it is likewise the trivial name of a species of anguis. See ANGUIS, and COLUBER.

CERASTIUM, in botany, a genus of the decandria pentagynia class. The calix has five leaves; the petals are bifid; and the capsule is unilocular, and opens at the top. There are sixteen species, seven of which are natives of Britain, *viz.* the vulgatum, or narrow-leaved mouse-ear chickweed; the viscosum, or broad-leaved mouse-ear chickweed; the semidecandrium, or least mouse-ear chickweed; the arvense, or corn mouse-ear chickweed; the alpinum, or mountain mouse-ear chickweed; the tomentosum, or wooly mouse-ear chickweed; and the aquaticum, or marsh mouse-ear chickweed.

CERASUS, in botany, the trivial name of a species of prunus. See PRUNUS.

CERATE, in pharmacy, a kind of ointment applied to ulcerations, excoriations, *&c.* There are four kinds of cerate, *viz.* the *white cerate*, which is composed of a quarter of a pint of olive-oil, four ounces of white wax, and half an ounce of spermaceti, liquified together and sharred till the cerate be cold. The *yellow cerate* is composed of half a pound of yellow basilicum ointment, and an ounce of yellow wax, melted together. The *ceratum epuloticum*, is composed of one pint of olive-oil, and of yellow wax and calamine prepared each half a pound. Liquify the wax with the oil, and, as soon as the mixture begins to grow stiff, sprinkle in the calamine, keeping them constantly stirring till the cerate is quite cold. The *mercurial cerate* is composed of yellow wax, hogs lard dried, each half a pound; three ounces of quick-silver; and one dram of simple balsam of sulphur. Melt the wax with the lard, then gradually add this mixture to the quick-silver and balsam of sulphur previously ground together.

CERATION, the name given by the ancients to the small seeds of the ceratonia, used by the Arabian physicians, as a weight to adjust the doses of medicines; as the grain weight with us took its rise from a grain of barley.

CERATION, or CERATIUM, was also a silver coin, equal to one third of an obolus.

CERATOCARPUS, in botany, a genus of the monœcia monandria class. The calix of the male is divided into two parts; it has no corolla; and the filament is long: The calix of the female consists of two leaves connected to the germen; it has no corolla; the styli are two; and the seeds are bicorned and compressed. There is but one species, *viz.* the arenarius, a native of Tartary.

CERATOCEPHALOIDES, in botany. See VERBESINA.

CERATOCEPHALUS, in botany. See BIDENS.

CERATOIDES, in botany. See URTICA.

CERATONIA, in botany, a genus of the polygamia polyœcia class. It is a native of Sicily, Crete, and other eastern countries.

CERATOPHYLLUM, in botany, a genus of the monœcia polyandria class. The calix of the male is divided into many segments; it has no corolla; and the stamina are from 16 to 20. The calix and corolla of the female are the same with those of the male; it has one pistil, no stylus, and one naked seed. There are two species, one of which, *viz.* the demersum or horned pondweed, is a native of Britain.

CERATUM, in pharmacy. See CERATE.

CERBERA, in botany, a genus of the pentandria monogynia class. The fruit is a drupa containing one seed. There are three species, all of them natives of the Indies.

CERCELE, in heraldry. A cross cercele is a cross which opening at the ends, turns round both ways, like a ram's horn. See CROSS.

CERCIS, in botany, a genus of the decandria monogynia class. The calix is five-teethed, and gibbous below; the corolla is papilionaceous, with a short vexillum under the wings; the capsule is a legumen. There are two species, none of them natives of Britain.

CEREBELLUM, in anatomy. See p. 286.

CEREBRUM, in anatomy. See p. 285.

CEREMONY, an assemblage of several actions, forms, and circumstances, serving to render a thing more magnificent and solemn; particularly used to denote the external rites of religious worship, the formalities of introducing ambassadors to audiences, *&c.*

Master of the CEREMONIES, an officer instituted by king James I. for the more honourable reception of ambassadors and strangers of quality: he wears about his neck a chain of gold, with a medal under the crown of Great Britain, having on one side an emblem of peace, with this motto, *beati pacifici*; and on the other, an emblem of war, with *dieu et mon droit*: his salary is three hundred pounds *per annum.*

Assistant master of the CEREMONIES is to execute the employment in all points, whensoever the master of the

the ceremonies is abfent. His falary is one hundred and forty-one pounds thirteen fhillings and fourpence *per annum.*

Marfhal of the CEREMONIES is their officer, being fubordinate to them both. His falary is one hundred pounds *per annum.*

CEREUS, in botany. See CACTUS.

CERIGO, or CYTHEREA, in geography, an ifland of the Archipelago, on the eaftern coaft of the Morea, and fifty miles north of the ifland of Candia. It is a mountainous country, between forty and fifty miles in circumference, and fituated in E. long. 23° 40′, and N. lat. 36°.

CERINTHE, in botany, a genus of the pentandria monogynia clafs. The limbus of the corolla is tubular and ventricofe, opening at the faux; the feeds are often four, and fometimes two. There are only two fpecies, none of them natives of Britain.

CERINTHIANS, in church-hiftory, Chriftian heretics, followers of Cerinthus, who lived and publifhed his herefy in the time of the apoftles themfelves. They did not allow that God was the author of the creatures, but faid that the world was created by an inferior power: they attributed to this creator an only fon, but born in time, and different from the world: they admitted feveral angels and inferior powers: they maintained that the law and the prophets came not from God, but from the angels; and that the God of the Jews was only an angel: they diftinguifhed between Jefus and Chrift; and faid, that Jefus was a mere man, born, like other men, of Jofeph and Mary; but that he excelled all other men in prudence and wifdom; that Jefus being baptized, the Chrift of the fupreme God, that is, the Holy Ghoft, defcended upon him; and that by the affiftance of this Chrift, Jefus performed his miracles. It was partly to refute this fect that St John wrote his gofpel.

CERINTHOIDES, in botany. See CERINTHE.

CEROPEGIA, in botany, a genus of the pentandria monogynia clafs. The limbus of the corolla is connivent; and the feeds are plumofe. There are two fpecies, both natives of India.

CERRUS, in botany. See ÆGILOPS.

CERTHIA, in ornithology, a genus belonging to the order of picæ. The beak of this genus is arched, flender, fharp, and triangular; the tongue is fharp at the point; and the feet are of the walking kind, *i. e.* having the toes open and unconnected. There are 25 fpecies, *viz.* 1. The familiaris, or creeper, is grey above and white underneath, with brown wings, and ten white fpots on the ten prime feathers. It is a native of Europe, creeps up trees, lays about 20 eggs, and feeds upon caterpillars and the eggs of infects. 2. The muraria, or wall-creeper, is afh-coloured, with yellow fpots on the wings. It frequents towers and old walls, in the holes of which it builds its neft. 3. The pufilla, is grey above, and white below; the eye-brows are white; the prime feathers of the wings are brown, and white on the outer edge. It is a native of India. 4. The capenfis, is grey, with blackifh wings, the outermoft prime feathers of which are edged with white: It is a native of the Cape of Good-Hope. 5. The olivacea, is olive-coloured above, and grey below, with the orbits of the eyes white. It is found in Madagafcar. 6. The currucaria is likewife olive above, but yellowifh below; and the prime wing-feathers are equal. It is a native of Ceylon. 7. The jugularis is greyifh above, and yellowifh below; the throat is of a violet colour; and the two outmoft prime feathers of the wings are yellow at the points. It is found in the Philippine Ifles. 8. The cærulea has a blue belt round the eyes; and the throat, and prime wing and tail feathers are black: The bill is very long. It is a native of Surinam. 9. The cayana is of a green fhining colour above, and ftreaked with white below. It is a native of Cayenne. 10. The chalybeata is green and fhining above; the breaft is red, and on the fore-part of it there is an iron-coloured belt. 11. The afra is green above; the breaft is red; the belly is white; and it has a fhort blue tail. The above two fpecies are found at the Cape of Good-Hope. 12. The fpiza is green, with the head and prime wing-feathers black. It is a native of Brafil. 13. The fperata is purple above, and red below; the head, throat, and tail, are violet. It is found in the Philippine Ifles. 14. The fenegalenfis is of a blackifh violet colour; the top of the head and throat are greenifh, and the breaft is red. It is a native of Senegal. 15. The gutturalis is greenifh; the throat is a fhining green, and the breaft is purple. It is a native of Brafil. 16. The pinus is yellow below, and olive above; the wings are blue, with two white belts. It is a native of North America. 17. The cruenta is blackifh above, and white below; the top of the head, the neck, and tail, are red. It is a native of Bengal. 18. The flaveola is black above, and yellow below; the eye-brows, and the tops of the outermoft prime wing-feathers, are white. It is a native of America. 19. The pulchella has a green fhining body, and a red breaft; the two intermediate prime wing-feathers are very long. It is a native of Senegal. 20. The famofa has the two intermediate prime wing-feathers very long; the body is of a fhining green; and the axillæ of the wings are yellow. It is found at the Cape of Good-Hope. 21. The philippina has the two intermediate wing-feathers very long, a greenifh grey body, and yellowifh underneath. It is a native of the Philippine Ifles. 22. The violacea has the two intermediate prime wing-feathers very long, a fhining violet-coloured body, and the breaft and belly are yellow. 23. The zeylonica has a green head, an iron-coloured back, a yellow belly, and the throat and tail are azure. It is a native of Ceylon. 24. The cyanea is blue, with a black belt round the eyes; the fhoulders, wings, and tail are black, and the feet are red. It is a native of Brafil and Cayenne. 25. The lotentia is blue, with a red belt over the breaft. It is a native of Ceylon.

CERTIORARI, a writ which iffues out of the chancery, directed to an inferior court, to call up the records of a caufe there depending, in order that juftice may be done. And this writ is obtained upon complaint, that the

the party who feeks it has received hard ufage, or is not like to have an impartial trial in the inferior court. A certiorari is made returnable either in the king's bench, common pleas, or in chancery.

It is not only iffued out of the court of chancery, but likewife out of the king's bench, in which laft mentioned court it lies where the king would be certified of a record. Indictments from inferior courts, and proceedings of the quarter-feffions of the peace, may alfo be removed into the king's bench by a certiorari; and here the very record muft be returned, and not a tranfcript of it; though ufually in chancery, if a certiorari be returnable there, it removes only a tenor of the record.

CERTITUDE, confidered in the things or ideas which are the objects of our underftanding, is a neceffary agreement or difagreement of one part of our knowledge with another: as applied to the mind, it is the perception of fuch agreement or difagreement; or fuch a firm well-grounded affent, as excludes not only all manner of doubt, but all conceivable poffibility of a miftake.

There are three forts of certitude, or affurance, according to the different natures and circumftances of things.

1. A phyfical or natural certitude, which depends upon the evidence of fenfe; as that I fee fuch or fuch a colour, or hear fuch or fuch a found: no body queftions the truth of this, where the organs, the medium, and the object are rightly difpofed. 2. Mathematical certitude is that arifing from mathematical evidence; fuch is, that the three angles of a triangle are equal to two right ones. 3. Moral certitude is that founded on moral evidence, and is frequently equivalent to a mathematical one; as that there was formerly fuch an emperor as Julius Cæfar, and that he wrote the Commentaries which pafs under his name; becaufe the hiftorians of thefe times have recorded it, and no man has ever difproved it fince: this affords a moral certitude, in common fenfe fo great, that one would be thought a fool or a madman for denying it.

CERVIA, in geography, a city and port town of Romania, in Italy, fituated on the gulph of Venice, about ten miles fouth-eaft of Ravenna, and fubject to the pope: E. long. 13°, and N. lat. 44° 30′.

CERVICAL *nerves*, in anatomy. See p. 251.

CERVIX, in anatomy. See p. 166.

CERVIX *of the uterus*. See p. 274.

CERUMEN, EAR-WAX. See p. 296.

CERUSE, or CERUSS, *white lead*, a fort of calx of lead, made by expofing plates of that metal to the vapour of vinegar.

The beft way of preparing it is the following: A glafs-cucurbit is to be cut off in fuch a manner as to leave it a very long mouth; an alembic head of glafs is to be fitted to this; fome vinegar is to be put into the body, and a number of thin plates of lead are to be placed in the head in fuch a manner that they may ftand fomewhat erect: when the head is fitted on, the body is to be fet in a gentle fand-heat for twelve hours; then unluting the veffels, the receiver, which had been fitted to the nofe of the head, will contain a fweet and ftyptic liquor, naufeous and turbid, called the vinegar of lead, or the folution of lead; and the plates of lead, taken out of the head, will be found covered with a white dufty matter; this is cerufs; and if the operation be repeated, the whole lead will be in fine reduced to this ftate of cerufs.

Cerufs is ufed externally either mixed in ointments, or by fprinkling it on old gleeting and watery ulcers, and in many difeafes of the fkin. If, when it is reduced into a fine powder, it is received in with the breath in infpiration, and carried down into the lungs, it caufes terrible afthmas, that are almoft incurable, and at laft generally prove fatal: fad inftances of the very pernicious effects of this metal are too often feen among thofe perfons who work lead in any form, but particularly among the workers in white-lead.

The painters ufe it in great quantities, and, that it may be afforded cheap to them, it is generally adulterated with common whiting: the Englifh and Dutch cerufs are very bad in this refpect: the Venetian ought always to be ufed by apothecaries.

CERUSS *of antimony*, a medicine prepared by diftilling powdered regulus of antimony with fpirit of nitre, till no more fumes arife; what remains in the retort being pulverifed and wafhed, makes the cerufs of antimony, which is efteemed a powerful diuretic.

CERVUS, or DEER, in zoology, a genus of quadrupeds belonging to the order of pecora. The horns are folid, brittle, covered with a hairy fkin, and growing from the top; they likewife fall off, and are renewed annually. There are eight fore-teeth in the under jaw, and they have no dog-teeth. The fpecies of this genus are feven, *viz.* 1. The camelopardalis, with fimple or unbranched horns, and the fore-feet remarkably longer than the hind feet. This is an uncommon animal, few of them having ever been feen in Europe. It is a native of Æthiopia, and is very mild and gentle; The head is like that of a ftag; its horns are blunt and about fix inches long. The neck refembles that of a camel, but much longer, being fometimes feven feet in length. The body is fmall, covered with white hair, and fpotted with red. He is eighteen feet in length from the tail to the top of the head; and when he holds up his head, it is fixteen feet from the ground. He feeds principally on the leaves of trees.

2. The alces, or elk, has palmated horns, without any proper ftem, and a flefhy protuberance on the throat. This is the largeft animal of the deer kind. At the fair of St Germain at Paris, in the year 1752, a female elk was exhibited as a fhow. It was caught in the year 1749, in a foreft of Red Ruffia, belonging to a Khan of Tartary. The height was fix feet feven inches, the length ten feet, and the thicknefs eight. The hair was long, like that of a wild boar. The fkin is faid to refift the force of a gun bullet. The elk is a very fwift animal; and he feeds upon leaves of alder, birch, willow, &c. When tamed, he devours large quantities of hay or bread. This animal is found in the northern woods of Europe, Afia, and America.

3. The

3. The elaphus, is a kind of elk, with cylindrical ramified horns, bent backwards. It is a native of the northern parts of Europe and Afia.

4. The tarandus, or rein-deer, is a native of Lapland, and the northern parts of Europe, Afia, and America. The horns are large, cylindrical, branched, and palmated at the tops. Two of the branches hang over the face. He is about the fize of a buck, of a dirty whitifh colour; the hairs of his fkin are thick and ftrong. Thefe animals are of great ufe to the Laplanders; they feed upon their flefh; they employ their finews in fewing the boards of fledges together, and their milk affords them good cheefe: They likewife make garments of their fkins. The rein-deer are always employed in drawing fledges along the fnowy mountains, where horfes cannot travel. In a beaten track, they will drag a fledge twenty-five miles a day. When the animal is tired, his mafter loofes him from the fledge, and he immediately fcrapes the fnow from the ground with his feet, and feeds upon a fpecies of liver-wort, called rein-deer liverwort, which is very plentiful in thefe countries. This is the only nourifhment they require.

5. The dama, or buck and doe, a well known animal, kept tame in parks; the horns are branched, compreffed, and palmated at the top. It is a native of Europe. Their flefh, which goes by the name of venifon, is in high repute with the luxurious. See Plate LXIII.

6. The capreolus, has erect, cylindrical, branched horns, and forked at the top. It is called by fome authors the Brafilian goat, and is a native of Europe and Afia.

7. The Guineenfis, is of a greyifh colour, and black underneath. It is a native of Guinea, and the fize and figure of its horns have not been hitherto defcribed with any precifion.

CERVUS *volans*, in zoology, a fynonime of a fpecies of lucanus. See LUCANUS.

CESARE, among logicians, one of the modes of the fecond figure of fyllogifms; the minor propofition of which is an univerfal affirmative, and the other two univerfal negatives: Thus,

CE No immoral books ought to be read:
SA But every obfcene book is immoral:
RE Therefore no obfcene book ought to be read.

CESSIO *bonorum*, in Scots law. The name of that action by which an infolvent debtor may apply for liberation from prifon, upon making over his whole real and perfonal eftate to his creditors. See SCOTS LAW, title, *Sentences and their execution.*

CESTRUM, in botany, a genus of the pentandria monogynia clafs. The corolla is tunnel-fhaped; and the berry is unilocular. There are two fpecies, both natives of America.

CESTUS, among ancient poets, a fine embroidered girdle faid to be worn by Venus, to which Homer afcribes the faculty of charming and conciliating love.

CETACEOUS, an appellation given to fifhes of the whale kind.

CETE, the name of Linnæus's feventh order of mammalia, comprehending the MONODON, BALÆNA, PHYSETER, and DELPHINUS; fee thefe articles.

CETERACH, in botany, the trivial name of a fpecies of afplenium. See ASPLENIUM.

CETTE, a port-town of Languedoc, in France, fituated on a bay of the Mediterranean, in E. long. 3° 16′, and N. lat. 43° 25′.

CETUS, in aftronomy, a conftellation of the fouthern hemifphere, comprehending twenty-two ftars in Ptolemy's catalogue, twenty-one in Tycho's, and in the Britannic catalogue feventy-eight.

CEUTA, a city of the kingdom of Fez, in Africa, fituated on the fouth fide of the ftreights of Gibraltar, almoft oppofite to it: W. long. 6° 30′, and N. lat. 35° 50′. It is a ftrong fortrefs, in the poffeffion of the Spaniards.

CEYLON, an ifland in the Indian ocean, fituated between 78° and 82° E. long. and between 6° and 10° N. lat. It is about two hundred and fifty miles long, and two hundred broad. The Dutch, who are in poffeffion of all the fea-coaft, monopolize all the cinnamon produced in the ifland, the king being obliged to keep in the centre of the ifland, in his capital of Candy.

CHABLAIS, a country of Savoy, with the title of duchy.

CHACO, a large country of South America, fituated between 19° and 27° S. lat.

CHÆROPHYLLUM, or CHERVIL, in botany, a genus of the pentandria digynia clafs. The involucrum is concave and reflected; the petals are cordated; and the fruit is fmooth and oblong. The fpecies are feven, only two of which are natives of Britain, *viz.* the fylveftre, or wild cicely, or cow-weed; and the tumulum, or wild chervil. The leaves of the chervil are gently aperient and diuretic, and at the fame time grateful to the palate and ftomach.

CHÆTODON, in ichthyology, a genus of fifhes belonging to the order of thoraci. The teeth are very numerous, thick, fetaceous, and flexile: The rays of the gills are fix. The back-fin and the fin at the anus are flefhy and fquamous. There are twenty-three fpecies, diftinguifhed from each other principally by the figure of the tail, and the number of fpines in the back-fin.

CHAFF-FINCH, in ornithology, the Englifh name of a fpecies of fringilla. See FRINGILLA.

CHAGRE, a fort at the mouth of a river of the fame name, a little fouth of Porto Bello: W. long. 82°, and N. lat. 9° 50′.

CHAIN, a long piece of metal compofed of feveral links or rings, engaged the one in the other. They are made of divers metals, fome round, fome flat, others fquare; fome fingle, fome double; and ferve to fo many ufes, that it would be tedious to give a particular account of them all.

CHAIN is alfo a kind of meafure in France, in the trade of wood for fuel: There are chains for wood by tale, for wood by the rope, for faggots, for cleft wood, and for round fticks. There are alfo chains meafuring the fheaves of all forts of corn, particularly with regard to the payment of tythes; for meafuring pottles of hay,

nay, and for meafuring horfes. All thefe are divided into feet, inches, hands, *&c.* according to the ufe they are defigned for.

CHAIN-*fhot*, two bullets with a chain between them. They are ufed at fea to fhoot down yards or mafts, and to cut the fhrouds or rigging of a fhip.

CHAIN, in furveying, a meafure of length, made of a certain number of links of iron-wire, ferving to take the diftance between two or more places.

Gunter's chain of 100 fuch links, each meafuring $7\frac{92}{100}$ inches, and confequently equal to 66 feet, or four poles. See SURVEYING.

CHAISE, a fort of light, open chariot, or calafh. See CHARIOT.

CHALAZA, among naturalifts, a white knotty fort of ftring at each end of an egg, formed of a plexus of the fibres of the membranes, whereby the yolk and white are connected together. See EGG.

CHALCEDONY, in natural hiftory, a genus of femi-pellucid gems, of an even and regular not tabulated texture, of a femi-opaque cryftaline bafis, and variegated with different colours, difperfed in form of mifts and clouds, and, if nicely examined, found to be owing to an admixture of various kinds of earths, but imperfectly blended in the mafs, and often vifible in diftinct moleculæ.

Of this genus there are a great many fpecies, as the bluifh-white chalcedony; the brownifh-black chalcedony, or fmoaky jafper or capnitis of the ancients; and the yellow and red chalcedony.

All the chalcedonies give fire readily with fteel, and make no effervefcence with aqua-fortis.

CHALCIDES, in zoology, the trivial name of a fpecies lacerta. See LACERTA.

CHALDEA, or BABYLONIA, the ancient name of a country of Afia, now called Eyrac Arabic.

CHALDEE, or CHALDAIC *language*, that fpoken by the Chaldeans, or people of Chaldea: It is a dialect of the Hebrew. See HEBREW.

CHALDRON, a dry Englifh meafure, confifting of thirty-fix bufhels, heaped up according to the fealed bufhel kept at Guild-hall, London: but on fhip-board, twenty-one chaldron of coals are allowed to the fcore. The chaldron fhould weigh two thoufand pounds.

CHALK, in natural-hiftory, the Englifh name of the white, dry marle, with a dufty furface, found in hard maffes, and called by authors *creta*, and *terra creta.*

Chalk thrown into water, raifes a great number of bubbles, with a hiffing noife, and flowly diffufes itfelf into an impalpable powder. It ferments more ftrongly with acids than any other earth, and burns to lime.

As a medicine, chalk deferves, perhaps, the higheft place among the alkaline abforbents; nor is it lefs ufeful in many of the ordinary affairs of life. Its ufe in cleaning various utenfils is well known; and it is in no fmall repute as a manure, efpecially for cold four lands; in which intention the foft unctuous chalk is moft proper, as the dry, hard, and ftrong chalk is for lime. It is a great improver of lands, and will even change the very nature of them. However, it is moft advifeable to mix one load of chalk, with two or three of dung, mud, or frefh mould, whereby it will become a lafting advantage to the ground: The common allowance is fourteen loads of chalk to every acre.

Black CHALK, among painters, denotes a kind of ochreous earth, of a clofe ftructure, and fine black colour, ufed in drawing upon blue paper.

Red CHALK, an indurated clayey ochre, common in the colour-fhops, and much ufed by painters and artificers.

CHALLONS *on the Marne*, the capital of the Challonois, in the province of Champaign in France, fituated eighty-two miles eaft of Paris, and thirty fouth-eaft of Reims: E. long. 4° 35′, N. lat. 48° 55′. It is a bifhop's fee.

CHALLONS *on the Soan*, a city of Burgundy in France, thirty-two miles fouth of Dijon: E. long. 5°, N. lat. 46° 40′. It is the fee of a bifhop.

CHALYBEAT, in medicine, an appellation given to any liquid, as wine or water, impregnated with particles of iron or fteel.

Dr Monro, profeffor of anatomy at Edinburgh, by pouring a tincture of galls into common water, and diffolving therein a fmall quantity of fal martis, adding fome filings of iron, and oil of vitrol, procured a water exactly like the natural chalybeat water; and he is of opinion, that where thefe are not to be had, the artificial water may be made to anfwer all their intentions, according to its being more or lefs clofely kept, or expofed in the air or heat, *&c.*

CHAM, or KHAN, a word of much the fame import with *king* in Englifh: It is the title of the fovereign princes of Tartary, and is likewife applied to the principal noblemen in Perfia.

CHAM, in geography, a town of the Bavarian palatinate, fituated on a river of the fame name, about twenty-five miles north-eaft of Ratifbon; E. long. 13°, N. lat. 49° 15′.

CHAMA, in zoology, a genus of fhell-fifh belonging to the order of vermes teftacea. The fhell is thick, and has two valves; it is an animal of the oyfter kind. Linnæus enumerates 14 fpecies, principally diftinguifhed by the figure of their fhells.

CHAMÆBATOS, in botany. See RUBUS.

CHAMÆBUXUS, in botany. See POLYGALA.

CHAMÆCERASUS, in botany. See LONICERA.

CHAMÆCLEMA, in botany. See HEDERA.

CHAMÆCRISTA, in botany. See CASSIA.

CHAMÆDAPHNE, in botany. See KALMIA.

CHAMÆDRYS, in botany. See VERONICA.

CHAMÆLEA, in botany. See CENORUM.

CHAMÆLEON, in zoology, the trivial name of a fpecies of lacerta. See LACERTA.

CHAMÆLINUM, in botany. See LINUM.

CHAMÆMILUM, in botany. See MATRICARIA.

CHAMÆNERION, in botany. See EPILOBIUM.

CHAMÆPITYS, in botany. See TEUCRIUM.

CHAMÆRHODODENDROS, in botany. See AZALEA.

CHAMÆROPS, or HUMBLE-PALM, in botany, a genus ranged under the palmæ flabellifoliæ of Linnæus. It is a native of Spain.

Privy-CHAMBER. Gentlemen of the privy-chamber, are ſervants of the king, who are to wait and attend on him and the queen at court, in their diverſions, *&c.* Their number is forty-eight under the lord-chamberlain, twelve of whom are in quarterly waiting, and two of theſe lie in the privy-chamber.

In the abſence of the lord-chamberlain, or vice-chamberlain, they execute the king's orders: at coronations, two of them perſonate the dukes of Aquitain and Normandy: and ſix of them, appointed by the lord-chamberlain, attend ambaſſadors from crowned heads to their audiences, and in public entries. The gentlemen of the privy-chamber were inſtituted by Henry VII.

CHAMBER, in policy, the place where certain aſſemblies are held, alſo the aſſemblies themſelves. Of theſe, ſome are eſtabliſhed for the adminiſtration of juſtice, others for commercial affairs.

Of the firſt kind are, 1. Star-chamber, ſo called, becauſe the roof was painted with ſtars; the authority, power, and juriſdiction of which are abſolutely aboliſhed by the ſtatute 17 Car. I. 2. Imperial chamber of Spire, the ſupreme court of judicatory in the empire, erected by Maximilian I. This chamber has a right of judging by appeal, and is the laſt reſort of all civil affairs of the ſtates and ſubjects of the empire, in the ſame manner as the aulic council of Vienna. Neverthelefs it is reſtrained in ſeveral caſes; it takes no notice of matrimonial cauſes, theſe being left to the pope; nor of criminal cauſes, which either belong to particular princes or towns in their reſpective territories, or are cognizable by all the ſtates of the empire in a diet. By the treaty of Oſnaburg, in 1648, fifty aſſeſſors were appointed for this chamber, whereof twenty-four were to be Proteſtants, and twenty-ſix Catholics; beſides five preſidents, two of them Proteſtants, and the reſt Catholics. 3. Chamber of accounts, a ſovereign court in France, where accounts are rendered of all the king's revenues, inventories, and avowels thereof regiſtered; oaths of fidelity taken, and other things relating to the finances tranſacted. There are nine in France, that of Paris is the chief; it regiſters proclamations, treaties of peace, naturalizations, titles of nobility, *&c.* All the members wear long black gowns of velvet, of ſattin, or damaſk, according to their places. 4. Eccleſiaſtical chambers in France, which judge by appeal of differences about collecting the tythes. 5. Chamber of audience, or grand chamber, a juriſdiction in each parliament of France, the counſellors of which are called *jugeurs*, or judges, as thoſe of the chamber of inqueſts are called *rapporteurs*, reporters of proceſſes by writing. 6. Chamber of the edict, or miparty, a court eſtabliſhed by virtue of the edict of pacification, in favour of thoſe of the reformed religion. This chamber is now ſuppreſſed. 7. Apoſtolical chamber of Rome, that wherein affairs relating to the revenues of the church and the pope are tranſacted. This council conſiſts of the cardinal-camerlingo, the governor of the rota, a treaſurer, an auditor, a preſident, one advocate-general, a ſolicitor-general, a commiſſary, and twelve clerks. 8. Chamber of London, an apartment in Guildhall, where the city-money is depoſited.

Of the laſt ſort are, 1. The chambers of commerce. 2. The chambers of aſſurance. And, 3. The royal or ſyndical chamber of bookſellers in France.

The chamber of commerce is an aſſembly of merchants and traders, where the affairs relating to trade are treated of. There are ſeveral eſtabliſhed in moſt of the chief cities of France; and in our own country, we have lately ſeen chambers of this kind erected for carrying on the Britiſh herring-fiſhery. Chamber of aſſurance in France, denotes a ſociety of merchants and others for carrying on the buſineſs of inſuring; but in Holland, it ſignifies a court of juſtice, where cauſes relating to inſurances are tried. Chamber of bookſellers in Paris, an aſſembly conſiſting of a ſyndic and aſſiſtants, elected by four delegates from the printers, and twelve from the bookſellers, to viſit the books imported from abroad, and to ſearch the houſes of ſellers of marbled paper, printſellers, and dealers in printed paper for hangings, who are prohibited from keeping any letters proper for printing books. In the viſitation of books, which ought to be performed by three perſons at leaſt from among the ſyndic and aſſiſtants, all libels againſt the honour of God and the welfare of the ſtate, and all books printed either within or without the kingdom in breach of their regulations and privileges, are ſtopt, even with the merchandiſes that may happen to be in the bales with ſuch libels, or other prohibited books. The days appointed for this chamber to meet, are Tueſdays and Fridays, at two o'clock in the afternoon.

CHAMBERLAIN, an officer charged with the management and direction of a chamber. See CHAMBER, *in policy*.

There are almoſt as many kinds of chamberlains as chambers, the principal whereof are as follows.

Lord CHAMBERLAIN *of Great Britain*, the ſixth great officer of the crown; to whom belongs livery and lodging in the king's court; and there are certain fees due to him from each archbiſhop or biſhop, when they perform their homage to the king; and from all peers at their creation, or doing their homage. At the coronation of every king, he is to have forty ells of crimſon velvet for his own robes. This officer, on the coronation-day, is to bring the king his ſhirt, coif, and wearing cloaths; and after the king is dreſſed, he claims his bed, and all the furniture of his chamber for his fees: he alſo carries at the coronation, the coif, gloves, and linen to be uſed by the king on that occaſion; alſo the ſword and ſcabbard, the gold to be offered by the king, and the robes-royal and crown: he dreſſes and undreſſes the king on that day, waits on him before and after dinner, *&c.*

To this officer belongs the care of providing all things in the houſe of lords, in the time of parliament; to him alſo belongs the government of the palace of Weſtminſter: he diſpoſes likewiſe of the ſword of ſtate, to be carried before the king, to what lord he pleaſes.

Lord CHAMBERLAIN *of the houfehold*, an officer who has the overfight and direction of all officers belonging to the king's chambers, except the precinct of the king's bed-chamber.

He has the overfight of the officers of the wardrobe at all his majefty's houfes, and of the removing wardrobes, or of beds, tents, revels, mufic, comedians, hunting, meffengers, *&c.* retained in the king's fer vice. He moreover has the overfight and direction of the ferjeants at arms, of all phyficians, apothecaries, furgeons, barbers, the king's chaplain, *&c* and adminifters the oath to all officers above ftairs.

Other chamberlains, are thofe of the king's court of exchequer, of North Wales, of Chefter, of the city of London, *&c.* in which cafes this officer is generally the receiver of all rents and revenucs belonging to the place whereof he is chamberlain.

In the exchequer there are two chamberlains, who keep a controulment of the pells of receipts and exitus, and have certain keys of the treafury, records, *&c.*

CHAMBERLAIN *of London* keeps the city-money, which is laid up in the chamber of London: he alfo prefides over the affairs of mafters and apprentices, and makes free of the city, *&c.*

His office lafts only a year, but the cuftom ufually obtains to re-chufe the fame perfon, unlefs charged with any mifdemeanor in his office.

CHAMBERRY, the capital of the duchy of Savoy, in Italy, fituated ninety miles north-weft of Turin, and forty-five fouth of Geneva: E. long. 5° 45′, N. lat. 45° 40′.

CHAMOIS, or CHAMOIS-GOAT, in zoology. See CAPRA.

CHAMPAIGN, a province of France, bounded by Picardy on the north, by Lorrain on the eaft, by Burgundy on the fouth, and by the ifle of France on the weft. Its capital is Troyes.

CHAMPAIN, or *point* CHAMPAIN, in heraldry, a mark of difhonour in the coat of arms of him who kills a prifoner of war after he has cried quarter.

CHAMPION, a perfon who undertakes a combat in the place or quarrel of another; and fometimes the word is ufed for him who fights in his own caufe.

It appears that champions, in the juft fenfe of the word, were perfons who fought inftead of thofe that, by cuftom, were obliged to accept the duel, but had a juft excufe for difpenfing with it, as being too old, infirm, or being ecclefiaftics, and the like. Such caufes as could not be decided by the courfe of common law, were often tried by fingle combat; and he who had the good fortune to conquer, was always reputed to have juftice on his fide. Champions who fought for intereft only, were held infamous; thefe hired themfelves to the nobility, to fight for them in cafe of need, and did homage for their penfion

CHAMPION *of the king*, a perfon whofe office it is, at the coronation of our kings, to ride armed into Weftminfter-hall, while the king is at dinner there, and, by the proclamation of a herald, make challenge to this effect, *viz.* "That if any man fhall deny the king's "title to the crown, he is there ready to defend it in "fingle combat, *&c.*" Which done, the king drinks to him, and fends him a gilt cup, with a cover, full of wine, which the champion drinks, and has the cup for his fee.

CHANCE, in a general fenfe, a term applied to events not neceffarily produced as the natural effects of any proper foreknown caufe. For the doctrine of chance and its application to games, *&c.* fee GAMING.

CHANCE-*medley*, in law, is the accidental killing of a man, not altogether without the killer's fault, though without any evil intention; and is where one is doing a lawful act, and a perfon is killed thereby: For, if the act be unlawful, it is felony.

CHANCEL, a particular part of the fabric of a Chriftian church; or that part of the choir between the altar and the baluftrade that inclofes it, where the minifter is placed at the celebration of the communion.

CHANCELLOR, an officer fuppofed originally to have been a notary or fcribe under the emperors, and named *cancellarius*, becaufe he fat behind a lattice, called in Latin *cancellus*, to avoid being crowded by the people.

According to a late treatife, the chancellor originally prefided over a political college of fecretaries, for the writing of treaties, and other public bufinefs; and the court of equity, under the old conftitution, was held before the king and his council, in the palace, where one fupreme court for bufinefs of every kind was kept. At firft the chancellor became a judge, to hear and determine petitions to the king, which were preferred to him; and in the end, as bufinefs increafed, the people addreffed their fuit to the chancellor, and not to the king; and thus the chancellor's equitable power, by degrees, commenced by prefcription.

Lord high CHANCELLOR *of Great Britain*, or *Lord keeper of the great feal*, is the higheft honour of the long robe, being made fo *per traditionem magni figilli, per dominum regem*, and by taking the oaths: He is the firft perfon of the realm next after the king, and princes of the blood, in all civil affairs; and is the chief adminiftrator of juftice, next the fovereign, being the judge of the court of chancery.

All other juftices are tied to the ftrict rules of the law in their judgment: But the chancellor is invefted with the king's abfolute power, to moderate the written law, governing his judgment purely by the law of nature and confcience, and ordering all things according to equity and juftice. In this refpect Staundford fays, the chancellor has two powers, one abfolute, the other ordinary: Meaning, that although by his ordinary power, in fome cafes, he muft obferve the forms of proceedings, as other inferior judges; yet in his abfolute power, he is not limited by the law, but by confcience and equity.

The lord chancellor not only keeps the king's great feal; but alfo all patents, commiffions, warrants, *&c.* from the king, are, before they are figned, perufed by him: He has the difpofition of all ecclefiaftical benefices

nefices in the gift of the crown under 20l. a year, in the king's books; and he is ſpeaker of the houſe of lords. See PARLIAMENT.

CHANCELLOR *of a cathedral*, an officer that hears leſſons and lectures read in the church, either by himſelf or his vicar; to correct and ſet right the reader when he reads amiſs; to inſpect ſchools; to hear cauſes; apply the ſeal; write and diſpatch the letters of the chapter; keep the books; take care that there be frequent preachings, both in the church and out of it; and aſſign the office of preaching to whom he pleaſes.

CHANCELLOR *of the dutchy of Lancaſter*, an officer appointed chiefly to determine controverſies between the king and his tenants of the dutchy-land, and otherwiſe to direct all the king's affairs belonging to that court. See DUTCHY-*court*.

CHANCELLOR *of the exchequer*, an officer who preſides in that court, and takes care of the intereſt of the crown.

He is always in commiſſion with the lord-treaſurer, for the letting of crown-lands, *&c.* and has power, with others, to compound for forfeitures of lands, upon penal ſtatutes: He has alſo great authority in managing the royal revenues, and in matters relating to the firſt-fruits.

CHANCELLOR *of the order of the garter, and other military orders*, is an officer who ſeals the commiſſions and mandates of the chapter and aſſembly of the knights, keeps the regiſter of their proceedings, and delivers acts thereof under the ſeal of their order.

CHANCELLOR *of an univerſity*, is he who ſeals the diplomas, or letters of degrees, proviſion, *&c.* given in the univerſity.

The chancellor of Oxford is uſually one of the prime nobility, choſen by the ſtudents themſelves in convocation. He is their chief magiſtrate; his office is, *durante vita*, to govern the univerſity, preſerve and defend its rights and privileges, convoke aſſemblies, and do juſtice among the members under his juriſdiction.

Under the chancellor is the vice-chancellor, who is choſen annually, being nominated by the chancellor, and elected by the univerſity in convocation: He is always the head of ſome college, and in holy orders. His proper office is to execute the chancellor's power, to govern the univerſity according to her ſtatutes, to ſee that officers and ſtudents do their duty, that courts be duly called, *&c.* When he enters upon his office, he chuſes four pro-vice-chancellors out of the heads of the colleges, to execute his power in his abſence.

The chancellor of Cambridge is alſo uſually one of the prime nobility, and in moſt reſpects the ſame as that in Oxford; only he does not hold his office *durante vita*, but may be elected every three years. Under the chancellor there is a commiſſary, who holds a court of record for all privileged perſons and ſcholars under the degree of maſter of arts, where all cauſes are tried and determined by the civil and ſtatute law, and by the cuſtom of the univerſity.

The vice-chancellor of Cambridge is choſen annually, by the ſenate, out of two perſons nominated by the heads of the ſeveral colleges and hall.

CHANCERY, the grand court of equity and conſcience, inſtituted to moderate the rigour of the other courts that are bound to the ſtrict letter of the law.

The juriſdiction of this court is of two kinds, ordinary or legal, and extraordinary or abſolute. The ordinary juriſdiction is that wherein the lord-chancellor, who is judge of this court, in his proceeding and judgment, is bound to obſerve the order and method of the common law; in ſuch caſes the proceedings, which were formerly in Latin, but now in Engliſh, are filed or enrolled in the petty-bag-office; and the extraordinary, or unlimited power is that juriſdiction which the court exerciſes in caſes of equity, wherein relief is to be had by bill and anſwer.

The ordinary court holds plea of recognizances acknowledged in the chancery, writs of *ſcire facias* for repeal of the king's letters-patent. *&c.* alſo of all perſonal actions by or againſt any officer of the court, and of ſeveral offences and cauſes by act of parliament; all original writs, commiſſions of bankrupts, of charitable uſes, of ideots, lunacy, *&c.* are iſſued hence.

The extraordinary court gives relief for and againſt infants, notwithſtanding their minority; for and againſt married women, notwithſtanding their overture. All frauds and deceits, for which there is no redreſs at common law; all breaches of truſt, confidances and accidents, as to relieve obligors, mortgagors, *&c.* againſt penalties and forfeitures, where the intention was to pay the debt, are here remedied. But in all caſes where the plantiff can have his remedy at law, he ought not to be relieved in chancery; and a thing which may be tried by a jury, is not triable in this court.

The court of chancery will not retain a ſuit for any thing under ten pounds value, except in caſes of charity, nor for lands, *&c.* under forty ſhillings *per ann.* In this court all patents, moſt ſorts of commiſſions, deeds between parties touching lands and eſtates, treaties with foreign princes, *&c.* are ſealed and enrolled. Out of it are iſſued writs to convene the parliament and convocation, proclamations and charters, *&c.* For the ſeveral officers belonging to the court of chancery, ſee the articles MASTER *of the rolls*, MASTERS *in chancery*, CLERK, *&c.*

CHANDELIER, in fortification, a kind of moveable parapet, conſiſting of a wooden frame, made of two upright ſtakes, about ſix feet high, with croſs planks between them; ſerving to ſupport faſcines to cover the pioniers.

CHANNEL, in geography, an arm of the ſea, or a narrow ſea between two continents, or between a continent and an iſland. Such are the Britiſh channel, St George's channel, the channel of Conſtantinople, *&c.*

CHANTILLY, a village in France, about ſeven leagues from Paris, where there is a magnificent palace and fine foreſt belonging to the duke of Bourbon.

CHANTOR, a ſinger in the choir of a cathedral. The word is almoſt grown obſolete, *choriſter* or *ſinging-man* being commonly uſed inſtead of it. All great chapters

chapters have chantors and chaplains to affift the canons, and officiate in their abfence.

CHANTOR is ufed by way of excellence for the præcentor or mafter of the choir, which is one of the firft dignities of the chapter. At St David's in Wales, where there is no dean, he is next in dignity to the bifhop. The ancients called the chantor *primicerius cantorum*. To him belonged the direction of the deacons and other inferior officers.

Chantors in the temple of Jerufalem, were a number of Levites employed in finging the praifes of God, and playing upon inftruments before his altar. They had no habits diftinct from the reft of the people; yet in the ceremony of removing the ark to Solomon's temple, the chantors appeared dreffed in tunics of byffus or fine linen. 2 Chron. v. 12.

CHANTRY, or CHAUNTRY, a church or chappel, endowed with lands, *&c.* for the maintenance of one or more priefts to fay mafs for the fouls of the donors. Hence,

CHANTRY-*rents*, are rents ftill paid to the crown by the purchafers of thofe lands.

CHAOS, that confufion in which matter lay when newly produced out of nothing at the beginning of the world, before God, by his almighty word, had put it into the order and condition wherein it was after the fix days creation.

CHAOS, in zoology, a genus of infects belonging to the order of vermes zoophyta. The body has no fhell or covering, and is capable of reviving after being dead to appearance for a long time: It has no joints or external organs of fenfation. There are five fpecies, moftly obtained by infufions of different vegetables in water, and only difcoverable by the microfcope.

CHAPEAU, in heraldry, an ancient cap of dignity worn by dukes, being fcartlet-coloured velvet on the outfide, and lined with a fur. It is frequently borne above an helmet inftead of a wreath, under gentlemen's crefts.

CHAPEL, or CHAPPEL, a place of divine worfhip, ferved by an incumbent under the denomination of a chaplain.

CHAPEL is alfo a name given to a printer's work-houfe; in which fenfe they fay, the laws of the chapel, the fecrets of the chapel.

Knights of the CHAPEL, called alfo poor knights of Windfor, were inftituted by Henry VIII. in his teftament. Their number was at firft thirteen, but has been fince augmented to twenty-fix. They affift in the funeral fervices of the kings of England: They are fubject to the office of the canons of Windfor, and live on penfions affigned them by the order of the garter. They bear a blue or red cloke, with the arms of St George on the left fhoulder.

CHAPELET, in the menage, a couple of ftirrup leathers, mounted each of them with a ftirrup, and joined at top in a fort of leather buckle, called the head of the chapelet, by which they are made faft to the pummel of the faddle, after being adjufted to the rider's length and bore. They are ufed both to avoid the trouble of taking up or letting down the ftirrups, every time that the gentleman mounts on a different horfe and faddle, and to fupply the place of the academy faddles, which have no ftirrups to them.

CHAPITERS, in architecture, the fame with capitals.

CHAPITERS, in law, formerly fignified a fummary of fuch matters as were inquired of, or prefented before juftices in eyre, juftices of affize or of the peace, in their feffions.

Chapiters, at this time, denote fuch articles as are delivered by the mouth of the juftice in his charge to the inqueft.

CHAPLAIN, an ecclefiaftic who officiates in a chapel. See CHAPEL.

The king of Great Britain hath forty-eight chaplains in ordinary, ufually eminent doctors in divinity, who wait four each month, preach in the chapel, read the fervice to the family, and to the king in his private oratory, and fay grace in the abfence of the clerk of the clofet. Befides, there are twenty-four chaplains at Whitehall, fellows of Oxford or Cambridge, who preach in their turns, and are allowed 30 l. *per annum* each. According to a ftatute of Henry VIII. the perfons vefted with a power of retaining chaplains, together with the number each is allowed to qualify, is as follows: An archbifhop, eight; a duke or bifhop, fix; marquefs or earl, five; vifcount, four; baron, knight of the garter, or lord-chancellor, three; a dutchefs, marchionefs, countefs, baronefs, the treafurer and comptroller of the king's houfe, clerk of the clofet, the king's fecretary, dean of the chapel, almoner, and mafter of the rolls, each of them two; chief juftice of the king's bench, and warden of the cinque-ports, each one. All thefe chaplains may purchafe a licence or difpenfation, and take two benefices with cure of fouls. A chaplain muft be retained by letters teftimonial under hand and feal; for it is not fufficient that he ferve as chaplain in the family.

CHAPLAIN *of the order of Malta*, otherwife called diaco, and clerk conventual, the fecond clafs of the order of Malta. The knights make the firft rank.

CHAPLET, a ftring of beads ufed by the Roman Catholics, to count the number of their prayers. The invention of it is afcribed to Peter the hermit, who probably learned it of the Turks, as they owe it to the Eaft-Indians.

Chaplets are fometimes called pater-nofters, and are made of coral, of diamonds, of wood, *&c.* The common chaplet contains fifty ave-marias, and five pater-nofters. There is alfo a chaplet of our Saviour, confifting of thirty-three beads, in honour of his thirty-three years living on earth, inftituted by father Michael the Camaldulian.

CHAPPE', in heraldry, the dividing an efcutcheon by lines drawn from the centre of the upper edge to the angles below, into three parts, the fections on the fides being of a different metal or colour from the reft.

CHAPPEL *in frith*, a market town of Derbyfhire, about twenty-fix miles north-weft of Derby; W. long. 1° 50′, N. lat. 53° 22′.

CHAPTER, in eccleſiaſtical polity, a ſociety or community of clergymen belonging to the cathedrals and collegiate-churches.

It was in the eighth century that the body of canons began to be called a chapter. The chapter of the canons of a cathedral were a ſtanding council to the biſhop, and, during the vacancy of the ſee, had the juriſdiction of the dioceſe. In the earlier ages, the biſhop was head of the chapter; afterwards abbots and other dignitaries, as deans, provoſts, treaſurers, *&c.* were preferred to this diſtinction. The deans and chapters had the privilege of chuſing the biſhops in England; but Henry VIII. got this power veſted in the crown: and as the ſame prince expelled the monks from the cathedrals, and placed ſecular canons in their room, thoſe he thus regulated were called deans and chapters of the new foundation; ſuch are Canterbury, Wincheſter, Ely, Carliſle, *&c.*

CHAPTER, in matters of literature, a diviſion in a book for keeping the ſubject treated of more clear and diſtinct.

CHARA, in botany, a genus of the cryptogamia algæ claſs. The calix conſiſts of two leaves; the antheræ are globular and ſeſſile; there are three ſtigmata, and one round ſeed The ſpecies are four, three of which are natives of Britain, *viz.* the tomentoſa, or brittle chara; the vulgaris, or common chara; the hiſpida, or rough chara; and the flexilis, or ſmooth chara.

CHARABON, a ſea-port town on the northern coaſt of the iſland of Java, in the Indian ocean, ſituated 130 miles eaſt of Batavia; E. long. 108°, ſouth lat. 6°.

CHARACTER, in a general ſenſe, denotes any mark whatever, ſerving to repreſent either things or ideas: thus letters are characters, types, or marks of certain ſounds; words, of ideas, *&c.*

Literal characters may be divided, with reſpect to the nations among whom they have been invented, into Greek characters, Roman characters, Hebrew characters, *&c* The Latin character now uſed through all Europe was formed from the Greek, as the Greek was from the Phœnician; and the Phœnician, as well as the Chaldee, Syriac, and Arabic characters, were formed from the ancient Hebrew, which ſubſiſted till the Babyloniſh captivity; for, after that event, the character of the Aſſyrians, which is the ſquare Hebrew now in uſe, prevailed, the ancient being only found on ſome Hebrew medals, commonly called Samaritan medals It was in 1091 that the Gothic characters, invented by Ulfilas, were aboliſhed, and the Latin ones eſtabliſhed in their room.

Medalliſts obſerve, that the Greek character, conſiſting only of majuſcule letters, has preſerved its uniformity on all medals, as low as the time of Gallienus; from that time it appears ſomewhat weaker and rounder: from the time of Conſtantine to Michael we find only Latin characters; and after Michael the Greek characters recommence; but from that time they begin to alter with the language, which was a mixture of Greek and Latin. The Latin medals preſerve both their character and language as low as the tranſlation of the ſeat of the empire to Conſtantinople: towards the time of Decius the character began to loſe its roundneſs and beauty; ſome time after, it retrieved, and ſubſiſted tolerably till the time of Juſtin, when it degenerated gradually into the Gothic. The rounder, then, and better formed a character is upon a medal, the fairer pretence it has to antiquity.

CHARACTER is alſo uſed, in ſeveral of the arts, for a ſymbol, contrived for the more conciſe and immediate conveyance of the knowledge of things. For the

Numeral CHARACTERS uſed to expreſs numbers, are either letters or figures. The Arabic character, called alſo the common one, becauſe it is uſed almoſt throughout Europe in all ſorts of calculations, conſiſts of theſe ten digits, 1, 2, 3, 4, 5, 6, 7, 8, 9, 0.

The Roman numeral character conſiſts of ſeven majuſcule letters of the Roman alphabet, *viz.* I, V, X, L, C, D, M. The I denotes one, V five, X ten, L fifty, C a hundred, D five hundred, and M a thouſand.

The I repeated twice makes two, II; thrice, three, III; four is expreſſed thus IV, as I before V or X takes an unit from the number expreſſed by theſe letters. To expreſs ſix, an I is added to a V, VI; for ſeven, two, VII: and for eight, three, VIII: nine is expreſſed by an I before X, thus IX.

The ſame remark may be made of the X before L or C, except that the diminution is by tens; thus, XL denotes forty, XC ninety, and LX ſixty. The C before D or M diminiſhes each by a hundred.

The number five hundred is ſometimes expreſſed by an I before a C inverted, thus, IƆ; and inſtead of M, which ſignifies a thouſand, an I is ſometimes uſed between two C's, the one direct, and the other inverted, thus CIƆ. The addition of C and Ɔ before or after, raiſes CIƆ by tens, thus, CCIƆƆ expreſſes ten thouſand, CCCIƆƆƆ, a hundred thouſand.

The Romans alſo expreſſed any number of thouſands by a line drawn over any numeral leſs than a thouſand; thus, $\overline{\text{V}}$ denotes five thouſand, $\overline{\text{LX}}$ ſixty thouſand: ſo likewiſe $\overline{\text{M}}$ is one million, $\overline{\text{MM}}$ is two millions, *&c.*

Some modern writers have admitted variations in this method of notation; thus we find IIX expreſſing eight, IICIX eighty-nine, Λ or V denoting IƆƆ, and ∞ or ⳩ ſtanding for CIƆ; whence ⳩ ten thouſand, Ψ Ψ twenty thouſand.

The Greeks had three ways of expreſſing numbers: firſt, every letter, according to its place in the alphabet, denoted a number, from α, one, to ω, twenty-four. 2. The alphabet was divided into eight units, α one, β two, γ three, *&c.* into eight tens, ι ten, κ twenty, λ thirty, *&c.* and eight hundreds, ρ one hundred, σ two hundred, τ three hundred, *&c.* 3. I ſtood for one, Π five, Δ ten, H a hundred, X a thouſand, M ten thouſand; and when the letter Π incloſed any of theſe, except I, it ſhewed the incloſed letter to be five times its value; as [Δ] fifty, [H] five hundred, [X] five thouſand, [M] fifty thouſand.

French CHARACTERS, uſed in the chamber of accounts, and by perſons concerned in the management of the revenue, is, properly ſpeaking, nothing elſe than the Roman numerals, in letters that are not majuſcule: thus, inſtead of expreſſing fifty-ſix by LVI, they denote it by ſmaller characters lvj.

CHARACTERS *upon tomb-ſtones.*

S. V. Siſte viator, *i. e.* Stop traveller.

M. S. Memoriæ ſacrum, *i. e.* Sacred to the memory.

D. M. Diis manibus.

I H S. Jeſus.

X. P. a character found in the catacombs, about the meaning of which authors are not agreed.

CHARACTER, in epic and dramatic poetry, that which is peculiar in the manners of any perſon, and diſtinguiſhes him from all others. See EPIC, *and dramatic compoſitions.*

CHARADRIUS, in ornithology, a genus belonging to the order of grallæ. The beak is cylindrical and blunt; the noſtrils are linear, and the feet have three toes. There are 12 ſpecies, *viz.* 1. The hiaticula, or ſea-lark of Ray, has a black breaſt, a white ſtreak along the front; the top of the head is brown; and the legs and beak are reddiſh. It is found on the ſhores of Europe and America. 2. The alexandrinus, or oriental dotterell, is of a browniſh colour, with the fore-head, collar, and belly white; the prime tail-feathers on both ſides are white; and the legs are black. It is a native of Egypt, and is much valued for its ſinging. It is about the ſize of a crow, and lives upon mice, rats, *&c.* 3. The vociferus, or noiſy plover of Cateſby, has black ſtreaks on the breaſt, neck, fore-head, and cheeks; and the feet are yellow. It is a native of North America. 4. The ægyptius, has a black ſtreak on the breaſt, white eye-brows, the prime tail-feathers ſtreaked with black at the points, and bluiſh legs. It is found in the plains of Egypt, and feeds on inſects. 5. The morinellus has an iron coloured breaſt, a ſmall white ſtreak on the breaſt and eye-brows, and black legs. It is the dotterell of Ray, and a native of Europe. 6. The apricarius has a black belly; the body is brown,

brown, and variegated with white and yellow ſpots; and the legs are aſh-coloured. It is the ſpotted plover of Edwards, and a native of Canada. 7. The pluvialis, is black above, with green ſpots, white underneath, and the feet are aſh-coloured. It is the green plover of Ray, and is a native of Europe. 8. The torquatus, has a black breaſt, and a white front; the top of the head and the collar is black; and the beak and feet are bluiſh. It is a native of St Domingo. 9. The calidris, has black feet and a black bill; the rump is greyiſh; and the body is pure white below. It frequents the ſhores of Europe. 10. The œdicnemus, or ſtone curlew of Ray, is of a grey colour, with two of the prime wing-feathers black, but white in the middle; it has a ſharp bill, and aſh-coloured feet. It is a native of Britain. 11. The luinantopus, is white below, with a black back, and a long black bill; the feet are red and very long. It is the autumnal dotterell of Engliſh authors, and frequents the ſea-ſhores of Europe. 12. Spinoſus, armed dotterell, or lap-wing, has a black breaſt, legs, and wings; it has a creſt on the hinder part of the head. It is of the ſize of a pidgeon; the French call it dominicanus, from the reſemblance it has to the dreſs of a dominican monk: It is a native of Egypt.

CHARANTIA, in botany. See MOMORDICA.

CHARAX, in ichthyology. See SALMO.

CHARBON, in the menage, that little black ſpot o mark which remains after a large ſpot in the cavity of the corner teeth of a horſe: about the ſeventh or eighth year, when the cavity fills up, the tooth being ſmooth and equal, it is ſaid to be raſed.

CHARCAS, the ſouthern diviſion of Peru, in South America, remarkable for the ſilver-mines of Potoſi.

CHARCOAL, a kind of fuel, conſiſting of half-burnt wood, much uſed by artificers of different profeſſions; and that not only as fuel, but for poliſhing braſs or copper-plates, *&c.*

The beſt charcoal for common uſes is that made of oak; but in the manufacture of gunpowder they commonly uſe charcoal made of alder.

CHARENTE, a river of France, which ariſing in the Limoſin, runs weſtward by Angouleſme and Saintes, falling into the bay of Biſcay, oppoſite to the iſle of Oleron.

CHARENTON, the name of two towns in France, the one upon the Marmaude, in the Bourbonois; the other in the iſle of France, near the confluence of the Marne with the Seine, about three miles ſouth-eaſt of Paris: E. long. 2° 30'; and N. lat. 48° 45'.

CHARGE, in heraldry, is applied to the figures repreſented on the eſcutcheon, by which the bearers are diſtinguiſhed from one another; and it is to be obſerved, that too many charges are not ſo honourable as fewer.

CHARGE *of lead* denotes a quantity of thirty-ſix pigs. See PIG.

CHARGE *to enter heir*, in Scots law, a writing paſſing under the ſignet, obtained at the inſtance of a creditor, either againſt the heir of his debitor, for fixing upon him the debt as repreſenting the debitor, which is called a general charge: Or, againſt the debitor himſelf, or his heir, for the purpoſe of veſting him in the right of any heritable ſubject to which he has made up no title, in order the creditor may attach that ſubject for payment of his debt, in the ſame manner as if his debitor or his heir were legally veſted in it by ſervice or otherwiſe. This laſt kind is called a ſpecial charge. See SCOTS LAW, title, *Appriſings and adjudications*.

CHARGED, in heraldry, a ſhield carrying ſome impreſs or figure, is ſaid to be charged therewith; ſo alſo when one bearing, or charge, has another figure added upon it, it is properly ſaid to be charged.

CHARIOT, a half coach, having only a ſeat behind, with a ſtool, at moſt, before. See COACH.

The chariots of the ancients, chiefly uſed in war, were called by the ſeveral names *bigæ*, *trigæ*, &c. according to the number of horſes applied to draw them. Every chariot carried two men, who were probably the warrior and the charioteer; and we read of ſeveral men of note and valour employed in driving the chariot. When the warriors came to encounter in cloſe fight, they alighted out of the chariot, and fought on foot; but when they were weary, which often happened, by reaſon of their armour, they retired into their chariot, and thence annoyed their enemies with darts and miſſive weapons. Theſe chariots were made ſo ſtrong, that they laſted for ſeveral generations.

Beſides this ſort, we find frequent mention of the *currus falcati*, or thoſe chariots armed with hooks, or ſcythes, with which whole ranks of ſoldiers were cut off together, if they had not the art of avoiding the danger; theſe were not only uſed by the Perſians, Syrians. Egyptians, *&c.* but we find them among our Britiſh anceſtors.

Triumphal CHARIOT was one of the principal ornaments of the Roman celebration of a victory.

The Roman triumphal chariot was generally made of ivory, round like a tower, or rather of a cylindrical figure; it was ſometimes gilt at the top, and ornamented with crowns; and, to repreſent a victory more naturally, they uſed to ſtain it with blood. It was uſually drawn by four white horſes, but oftentimes by lions, elephants, tygers, bears, leopards, dogs, *&c.*

CHARISTIA, a feſtival of the ancient Romans, celebrated in the month of February, wherein the relations by blood and marriage met, in order to preſerve a good correſpondence; and that, if there happened to be any difference among them, it might be the more eaſily accommodated, by the good humour and mirth of the entertainment.

CHARITY, among divines, one of the three grand theological virtues, conſiſting in the love of God and of our neighbour, or the habit and diſpoſition of loving God with all our heart, and our neighbour as ourſelves.

CHARITY *of St Hippolitus*, a religious congregation founded, about the end of the XIVth century, by one Bernardin Alvarez, a Mexican, in honour of St Hippolitus

Hippolitus the martyr, patron of the city of Mexico; and approved by pope Gregory XIII.

CHARLEMONT, a town of the province of Namur, in the Auftrian Netherlands, about eighteen miles fouth of Namur: E. long. 4° 40′, and N. lat. 50° 10′.

CHARLEMONT is alfo the name of a town of Ireland, fituated on the river Blackwater, in the county of Armagh, and province of Ulfter, about fix miles fouth-eaft of Dungannon: W. long. 6° 50′, and N. lat. 50° 16′.

CHARLEROY, a ftrong town in the province of Namur, in the Auftrian Netherlands, fituated on the river Sambre, about nineteen miles weft of Namur: E. long. 4° 20′, and N. lat. 50. 30′.

CHARLES's CAPE, a promontory of Virginia, in North America, forming the northern head-land of the ftreight that enters the bay of Cheafepeak.

CHARLES's-FORT, a fortrefs in the county of Cork, and province of Munfter in Ireland, fituated at the mouth of Kinfale harbour: W. long. 8° 20′, and N. lat. 51° 21′.

CHARLES's-TOWN, the capital of South Carolina, in North America, fituated on a peninfula formed by Afhley and Cooper rivers, the former of which is navigable for fhips twenty miles above the town: W. long. 79°, and N. lat. 32° 30′.

CHARLES's-WAIN, in aftronomy, feven ftars in the conftellation called *urfa major*. or the great bear.

CHARLETON, an ifland at the bottom of Hudfon's-bay, in North America, fubject to Great Britain: W. long. 80°, and N. lat. 52° 30′.

CHARLOCK, the Englifh name of the raphanus. See RAPHANUS.

CHARM, a term derived from the Latin *carmen*, a verfe; and ufed to denote a magic power, or fpell, by which, with the affiftance of the devil, forcerers and witches were fuppofed to do wonderful things, far furpaffing the power of nature.

CHARNEL, or CHARNEL-HOUSE, a kind of portico, or gallery, ufually in or near a church-yard, over which were anciently laid the bones of the dead, after the flefh was wholly confumed.

Charnel-houfes are now ufually adjoining to the church.

CHARNUB, in botany. See CERATONIA.

CHART, or SEA-CHART, an hydrographical map, or a projection of fome parts of the earth's fuperficies *in plano*, for the ufe of navigators. See NAVIGATION.

CHARTA-*magna*. See MAGNA *charta*.

CHARTER, in law, a written inftrument or evidence of things acted between one perfon and another.

Charters of private perfons, are deeds and inftruments for the conveyance of lands, *&c.* Here the purchafer of land fhall have all the charters and deeds, as incident to the fame, and for the maintenance of his title. But this is underftood where the feoffer is not bound to a general-warranty of the land.

CHARTER, in Scots law, that writing which contains the grant of a feudal fubject to the vaffal. See SCOTS LAW, tit. *Of the conftitution of heritable rights*.

CHARTOPHYLAX, the name of an officer of the church of Conftantinople, who attends at the door of the rails when the facrament is adminiftered, and gives notice to the priefts to come to the holy table. He reprefents the patriarch upon the bench, tries all ecclefiaftical caufes, keeps all the marriage regifters, affifts at the confecration of bifhops, and prefents the bifhop elect at the folemnity, and likewife all other fubordinate clergy. This office refembles in fome fhape that of the bibliothecarius at Rome.

CHARTRES, a large city of France, in the province of Orleanois, fituated on the river Eure, about forty-two miles fouth-weft of Paris: E. long. 1° 32′, N. lat. 48° 27′. It is a bifhop's fee.

CHARTREUSE, or CHARTREUSE-GRAND, a celebrated monaftery, the capital of all the convents of the Carthufian monks, fituated on a fteep rock in the middle of a large foreft of fir-trees, about feven miles north-eaft of Grenoble, in the province of Dauphine in France: E. long. 5° 5′, N. lat. 45° 20′. See CARTHUSIANS.

From this mother-convent, all the others of the fame order take their name; among which was the Chartreufe of London, corruptly called the charter-houfe, now converted into an hofpital, endowed with a revenue of 600 l. *per ann.*

Here are maintained eighty decayed gentlemen, not under fifty years of age: Alfo forty boys are educated and fitted either for the univerfity or trades. Thofe fent to the univerfity, have an exhibition of 20 l. a year for eight years; and have an immediate title to nine church-livings in the gift of the governors of the hofpital, who are fixteen in number, all perfons of the firft diftinction, and take their turns in the nomination of penfioners and fcholars.

CHARYBDIS, a rock in the ftrait of Meffina, between Italy and Sicily, much celebrated in the writings of ancient poets.

CHARYBDIS is alfo an appellation given by Dr Plot to certain openings in the bottom of the fea, whereby the water is conveyed to the origin or fources of fprings, rivers, *&c.* fuch is Maelftroom, on the coaft of Norway, fuppofed to be. See MAELSTROOM.

CHASING *of gold, filver*, &c. See ENCHASING.

CHASTE-*tree*. See VITEX.

CHATELET, the name of certain courts of juftice eftablifhed in feveral cities in France. The grand chatelet at Paris, is the place where the prefidial or ordinary court of juftice of the provoft of Paris is kept; confifting of a prefidial, a civil chamber, a criminal chamber, and a chamber of policy. The little chatelet is an old fort, now ferving as a prifon.

CHATHAM, a port-town of Kent, adjoining to Rochefter, fituated on the river Medway, thirty miles fouth-eaft of London: E. long. 40′, N. lat. 51° 20′.

It is the principal ftation of the royal navy, furnifhed with timber, rope-yards, and all manner of naval ftores, fufficient for the building and fitting out the largeft fleet.

CHATTEAU-CAMBRESIS, a town of the Cambrefis, in the French Netherlands, fituated on the river Selle,

Selle, thirteen miles fouth-eaft of Cambray, E. long. 3° 25′, N. lat. 50° 6′.

CHATTEAU DAUPHINE, a fortrefs fituated on the frontiers of Piedmont, in the province of Dauphine, but yielded to the king of Sardinia: E. long. 6° 40′, N. lat. 44° 30′.

CHATTELS, in law, all forts of goods moveable and immoveable, except fuch as are in the nature of freehold.

CHATTIGAN, a port-town of India, in the province of Bengal, fituated at the mouth of the moft eafterly branch of the Ganges, fubject to the Mogul: E. long. 91°, N. lat. 23°.

CHATTILLON, a town of Burgundy in France, about fixteen miles fouth-weft of Geneva: E. long. 5° 40′, N. lat. 46° 16′.

CHATTILLON is likewife the name of feveral other towns of France, fituated upon the Indre, the Loing, the Loire, the Marne, the Saone, *&c.*

CHAUMONT, the name of two towns in France; the one fituated in the ifle of France, thirty miles north-weft of Paris, E. long. 2°, N. lat. 49° 18′; the other fituated on the river Marne, in the province of Champaign, E. long. 5° 15′, N. lat. 48° 12′.

CHAUSE-TRAPE. See CALTROP.

CHEADLE, a market-town of Staffordfhire, ten miles north-eaft of Stafford: W. long. 2°, N. lat. 53°.

CHEASPEAK-BAY, a large frith or arm of the fea, which runs up about three hundred miles into the country between Virginia and Maryland, in North America: It is navigable almoft all the way for large fhips; being about twenty miles broad at the entrance between Charles-cape and Cape Henry, and between twenty and thirty miles broad afterwards. See CHARLES-CAPE.

CHECAYA, in Turkifh affairs, the fecond officer of the janizaries, who commands them under the aga, and is otherwife called *protogero.*

There is alfo a checaya of the treafury, ftables, kitchen, *&c.* the word fignifying as much as lieutenant, or the fecond in any office.

CHECK, or CHECK-ROLL, a roll or book, wherein is contained the names of fuch perfons as are attendants and in pay to the king, or other great perfonages, as their houfehold fervants.

Clerk of the CHECK, in the king's houfehold, has the check and controulment of the yeomen of the guard, and all the ufhers belonging to the royal family, allowing their abfence or defects in attendance, or diminifhing their wages for the fame, *&c.* He alfo, by himfelf or deputy, takes the view of thofe that are to watch in the court, and has the fetting of the watch, *&c.*

Clerk of the CHECK, in the king's navy at Plymouth, is alfo the name of an officer invefted with the like power.

CHECK, in falconry, a term ufed of a hawk when fhe forfakes her proper game, to flie at pyes, crows, rooks, or the like, that crofs her in her flight.

CHECKY, in heraldry, is when the fhield, or a part thereof, as a bordure, *&c.* is chequered, or divided into chequers or fquares, in the manner of a chefs-board.

This is one of the moft noble and moft ancient figures ufed in armory; and a certain author faith, that it ought to be given to none but great warriors, in token of their bravery: For the chefs-board reprefents a field of battle; and the pawns of men, placed on both fides, reprefent the foldiers of the two armies, which move, attack, advance, or retire, according to the will of the gamefters, who are the generals.

This figure is always compofed of metal and colour: But fome authors would have it reckoned among the feveral forts of furs.

CHEEK, in anatomy, that part of the face fituated below the eyes, on each fide. See p. 305.

CHEESE, a fort of food, prepared of curdled milk, purged from the ferum or whey, and afterwards dried for ufe.

Phyficians condemn the too free ufe of cheefe, by reafon it loads the ftomach when new, and heats and inflames when old.

Every country has its places noted for this commodity: Thus Chefter and Gloucefter-cheefe are famous in England; and the Parmefan cheefe is in no lefs repute abroad, efpecially in France. This fort of cheefe is entirely made of fweet cow's milk: But at Rochfort in Languedoc, they make cheefe of ewe's milk; and in other places, it is ufual to add goat or ewe's milk, in a certain proportion, to that of cow's.

There is likewife a kind of medicated cheefe, made by intimately mixing the expreffed juice of certain herbs, as fage, baum, mint, *&c.* with the curd, before it is fafhioned into a cheefe. The 100 weight of cheefe pays on importation, 1 s. $3\frac{4}{10}$ d. and draws back, on exportation, 1 s. $1\frac{1}{2}$ d. at the rate of 6 s. 8 d. The cheefe of Ireland is prohibited to be imported.

CHEESE-RUNNET, in botany. See GALLIUM.

CHEGFORD, a market-town of Devonfhire, about thirteen miles weft of Exeter: W. long. 4°, N. lat. 50° 40′.

CHEIRANTHUS, in botany, a genus of the tetradynamia filiquofa clafs. The germen has teeth-like glands on each fide; the calix is clofe, and confifts of two fmall leaves, gibbous at the bafe; and the feeds are plain. There are thirteen fpecies, only two of which are natives of Britain, *viz.* the cheiri, wall-flower, or wild cheir; and the tricufpidatus, or fea ftock-gilly-flower. The leaves of the wall-flower are faid to be cordial, anodyne, aperient, and emmenagogue; but are wholly neglected in practice.

CHEKAO, a kind of pafte prepared by calcination and trituration from a hard ftony fubftance, and afterwards wafhing the powder in large quantities of fair water.

The Chinefe ufe the chekao in drawing the elegant figures we fee in the wholly white china-ware, which they afterwards varnifh in the common way. See CHINA-WARE.

CHEKAIM, a province of China, bounded by that of Nankin on the north and by the ocean on the eaft.

CHELÆCANCRORUM, in the materia medica. See CRAB's CLAWS.

CHELIDONIUM, in botany, a genus of the polyandria monogynia clafs. The corolla has four petals;

the calix consists of two leaves; and the pod is linear and unilocular. There are four species, three of which are natives of Britain, *viz.* the majus, or celandine; the glaucium, or yellow horned poppy; and the hybridum, or violet-coloured horned poppy. The leaves and root of the majus, or celandine, are stimulating, aperient, diuretic, and sudorific: It is peculiarly recommended in the slow kind of jaundice, where there are no symptoms of inflammation, and in dropsies.

CHELIDONIUS *lapis*, in natural-history, a stone said by the ancients to be found in the stomachs of young swallows, and greatly cried up for its virtues in the falling-sickness; but from their description, it appears to be only a species of lycodontes, or bufonitæ. See LYCODONTES, and BUFONITÆ.

CHELM, a town of Poland, capital of a palatinate of the same name: It is situated in the province of Red Russia, 110 miles south-east of Warsaw: E. long. 23° 30′, N. lat. 51° 25′.

CHELMSFORD, the county town of Essex, situated on the river Chelmer, twenty five miles north-east of London: E. long. 30′, N. lat. 51° 40′. It sends two members to parliament.

CHELONE, in botany, a genus of the didynamia angiospermia class. The calix is divided into five parts; there are the rudiments of a fifth filament betwixt the two higher stamina; and the capsule is bilocular. There are three species, none of them natives of Britain.

CHELSEA, a fine village situated on the northern bank of the river Thames, a mile westward of Westminster, remarkable for a magnificent hospital of invalids and old decrepit soldiers; and a pleasure-house, called Ranelagh, to which a great deal of fine company resort in summer.

CHELTENHAM, or CHILTHENHAM, a market-town of Gloucestershire, seven miles north-east of Gloucester: W. long. 2° 10′, N. lat. 51° 50′. It is chiefly remarkable for its mineral waters, of the same kind with those of Scarborough. See SCARBOROUGH.

CHEMISE, in fortification, the wall with which a bastion, or any other bulwark of earth, is lined for its greater support and strength: Or it is the solidity of the wall from the talus to the stone-row.

Fire-CHEMISE, a piece of linen cloth, steeped in a composition of oil of petrol, camphor, and other combustible matters, used at sea, to set fire to an enemy's vessel.

C H E M I S T R Y.

THE object and chief end of chemistry is to separate the different substances that enter into the composition of bodies; to examine each of them apart; to discover their properties and relations; to decompose those very substances, if possible; to compare them together, and combine them with others; to reunite them again into one body, so as to reproduce the original compound with all its properties; or even to produce new compounds that never existed among the works of nature, from mixtures of other matters differently combined.

But this analysis, or decomposition, of bodies is finite; for we are unable to carry it beyond a certain limit. In whatever way we attempt to go further, we are always stopped by substances in which we can produce no change, and which are incapable of being resolved into others.

To these substances we may give the title of *principles* or *elements*. Of this kind the principal are earth, water, air, and fire. For though there be reason to think, that these are not the first component parts, or the most simple elements, of matter; yet, as we know by experience, that our senses cannot possibly discover the principles of which they are themselves composed, it seems more reasonable to fix upon them, and consider them as simple homogeneous bodies, and the principles of the rest, than to tire our minds with vain conjectures about the parts or elements of which they may consist.

Before entering upon the examination of compound substances, it is necessary to consider the most simple ones, or the four first principles, with some attention.

PART I. THEORY OF CHEMISTRY.

Of the Principles of Bodies.

Of AIR.

AIR is that fluid which we constantly breathe, and which encompasses the whole surface of the terrestrial globe. Being heavy, like other bodies, it penetrates into all places that are not either absolutely inaccessible, or filled with some other body heavier than itself. Its principal property is, to be susceptible of condensation and rarefaction; so that the very same quantity of air may occupy a much greater, or a much smaller space, according to the different state it is in. Heat and cold are the most usual causes of its condensation and rarefaction: For if a certain quantity of air be heated, its bulk enlarges

larges in proportion to the degree of heat applied to it; the consequence whereof is, that the same space now contains fewer particles of air than it did before. Cold again produces just the contrary effect.

On this property which air has of being condensed and dilated by heat, its elasticity chiefly depends. For if air were forced by condensation into a less compass than it took up before, and then exposed to a very considerable degree of cold, it would remain quite inactive, without exerting such an effort as it usually makes against the depressing body. On the other hand, the elasticity of heated air arises only from hence, that being rarefied by the action of fire, it requires much more room than it occupied before.

Air enters into the composition of many substances, especially vegetable and animal bodies: For by analysing most of them such a considerable quantity thereof is extricated, that some naturalists have suspected it to be altogether destitute of elasticity when thus combined with the other principles in the composition of bodies. According to them, the efficacy of the elastic power of the air is so prodigious, and its force when compressed so excessive, that it is not possible the other component parts of bodies should be able to confine so much of it in that state of compression which it must needs undergo, if retaining its elasticity when pent up among them.

However that be, this elastic property of the air produces the most singular and important phenomena observable in the resolution and composition of bodies.

Of WATER.

WATER is a thing so well known, that it is almost needless to attempt giving a general idea of it here. Every one knows that it is a transparent, insipid substance, and usually fluid. We say it is usually so; for being exposed to a certain degree of cold, it becomes solid: Solidity therefore seems to be its most natural state.

Water exposed to the fire grows hot; but only to a limited degree, beyond which its heat never rises, be the force of fire applied to it ever so violent: It is known to have acquired this degree of heat by its boiling up with great tumult. Water cannot be made hotter, because it is volatile, and incapable of enduring the heat without being evaporated and entirely dissipated.

If such a violent and sudden heat be applied to water as will not allow it time to exhale gently in vapours, as when, for instance, a small quantity thereof is thrown upon a metal in fusion, it is dissipated at once with vast impetuosity, producing a most terrible and dangerous explosion. This surprising effect may be deduced from the instantaneous dilatation of the parts of the water itself, or rather of the air contained in it. Moreover, water enters into the texture of many bodies, both compound and secondary principles; but, like air, it seems to be excluded from the composition of all metals, and most minerals. For although an immense quantity of water exists in the bowels of the earth, moistening all its contents, it does not therefore follow, that it is one of the principles of minerals. It is only interposed between their parts; for they may be entirely robbed of it, without any sort of decomposition: Indeed it is not capable of an intimate connection with them.

Of EARTH.

WE observed, that the two principles above treated of are volatile; that is, the action of fire separates them from the bodies they help to compose. But earth is fixed, and, when absolutely pure, resists the utmost force of fire. So that, whatever remains of a body, after it hath been exposed to the power of the fiercest fire, must be considered as containing nearly all its earthy principle, and consisting chiefly thereof.

Earth therefore is a fixed principle which is permanent in the fire. There is reason to think it very difficult, if not impossible, to obtain the terrene principle wholly free from every other substance: For after our utmost endeavours to purify them, the earths we obtain from different compounds are found to have different properties, according to the different bodies from which they are procured; or else, if those earths be pure, we must allow them to be essentially different, seeing they have different properties.

Earth, in general, with regard to its properties, may be distributed into *fusible* and *unfusible*; that is, into earth that is capable of melting or becoming fluid in the fire, and earth that constantly remains in a solid form, never melting in the strongest degree of heat to which we can expose it.

The former is also called *vitrifiable*, and the latter *unvitrifiable* earth; because, when earth is melted by the force of fire, it becomes what we call *glass*, which is nothing but the parts of earth brought into nearer contact, and more closely united by the means of fusion. Perhaps the earth, which we look upon as uncapable of vitrification, might be fused if we could apply to it a sufficient degree of heat. It is at least certain, that some earths, or stones, which separately resist the force of fire, so that they cannot be melted, become fusible when mixed together. Experience convinced Mr du Hamel, that lime-stone and slate are of this kind. It is however undoubtedly true, that one earth differs from another in its degree of fusibility: And this gives ground to believe, that there may be a species of earth absolutely unvitrifiable in its nature, which, being mixed in different proportions with fusible earths, renders them difficult to melt.

Whatever may be in this, as there are earths which we are absolutely unable to vitrify, that is a sufficient reason of our division of them. Unvitrifiable earths seem to be porous, for they imbibe water; whence they have also got the name of *absorbent earths*.

Of FIRE.

THE matter of the sun, or of light, the phlogiston, fire, the sulphureous principle, the inflammable matter, are all of them names by which the element of fire is usually denoted. But it should seem, that an accurate distinction hath not yet been made between the different states in which it exists; that is, between the phenomena of

of fire actually exiſting as a principle in the compoſition of bodies, and thoſe which it exhibits when exiſting ſeparately and in its natural ſtate: nor have proper diſtinct appellations been deſigned to it in thoſe different circumſtances. In the latter ſtate we may properly give it the names of fire, matter of the ſun, of light, and of heat; and may conſider it as a ſubſtance compoſed of infinitely ſmall particles, continually agitated by a moſt rapid motion, and of conſequence eſſentially fluid.

This ſubſtance, of which the ſun may be called the general reſervoir, ſeems to flow inceſſantly from that ſource, diffuſing itſelf over the world, and through all the bodies we know; but not as a principle, or eſſential part of them, ſince they may be deprived thereof, at leaſt in a great meaſure, without ſuffering any decompoſition. The greateſt change produced on them, by its preſence or its abſence, is the rendering them fluid or ſolid: ſo that all other bodies may be deemed naturally ſolid; fire alone eſſentially fluid, and the principle of fluidity in others. This being preſuppoſed, air itſelf might become ſolid, if it could be entirely deprived of the fire it contains; as bodies of moſt difficult fuſion become fluid, when penetrated by a ſufficient quantity of the particles of fire.

One of the chief properties of this pure fire is to penetrate eaſily into all bodies, and to diffuſe itſelf among them with a ſort of uniformity and equality: for if a heated body be contiguous to a cold one, the former communicates to the latter all its exceſs of heat, cooling in exact proportion as the other warms, till both come to have the very ſame degree of heat. Heat, however, is naturally communicable ſooneſt to the upper parts of a body; and conſequently, when a body cools, the under parts become ſooneſt cold. It hath been obſerved, for inſtance, that the lower extremity of a heated body, freely ſuſpended in the air, grows cold ſooner than the upper; and that when a bar of iron is red-hot at one end, and cold at the other, the cold end is much ſooner heated by placing the bar ſo that the hot end may be undermoſt, than when that end is turned uppermoſt. The levity of the matter of fire, and the vicinity of the earth, may poſſibly be the cauſes of this phenomenon.

Another property of fire is to dilate all bodies into which it penetrates. This hath already been ſhewn with regard to air and water; and it produces the ſame effect on earth.

Fire is the moſt powerful agent we can employ to decompoſe bodies; and the greateſt degree of heat producible by man, is that excited by the rays of the ſun collected in the focus of a large burning-glaſs.

Of the PHLOGISTON.

FROM what hath been ſaid concerning the nature of fire, it is evidently impoſſible for us to fix and confine it in any body. Yet the phenomena attending the combuſtion of inflammable bodies ſhew that they really contain the matter of fire as a conſtituent principle. By what mechaniſm then is this fluid, ſo ſubtile, ſo active, ſo difficult to confine, ſo capable of penetrating into every other ſubſtance in nature, ſo fixed as to make a component part of the moſt ſolid bodies? It is no eaſy matter to give a ſatisfactory anſwer to this queſtion. But without pretending to gueſs the cauſe of the phenomenon, let us reſt contented with the certainty of the fact, the knowledge of which will undoubtedly procure us conſiderable advantages. Let us therefore examine the properties of fire thus fixed and become a principle of bodies. To this ſubſtance, in order to diſtinguiſh it from pure and unfixed fire, the chemiſts have aſſigned the peculiar title of the *Phlogiſton*, which is indeed no other than a Greek word for the inflammable matter; by which latter name, as well as by that of the ſulphureous principle, it is alſo ſometimes called. It differs from elementary fire in the following particulars. 1. When united to a body, it communicates to it neither heat nor light. 2. It produces no change in its ſtate, whether of ſolidity or fluidity; ſo that a ſolid body does not become fluid by the acceſſion of the phlogiſton, and *vice verſa*; the ſolid bodies to which it is joined being only rendered thereby more apt to be fuſed by the force of the culinary fire. 3. We can convey it from the body with which it is joined into another body, ſo that it ſhall enter into the compoſition thereof, and remain fixed in it.

On this occaſion both theſe bodies, that which is deprived of the phlogiſton and that which receives it, undergo very conſiderable alterations; and it is this laſt circumſtance in particular that obliges us to diſtinguiſh the phlogiſton from pure fire, and to conſider it as the element of fire combined with ſome other ſubſtance, which ſerves it as a baſis for conſtituting a kind of ſecondary principle. For if there were no difference between them, we ſhould be able to introduce and fix pure fire itſelf where-ever we can introduce and fix the phlogiſton: yet this is what we can by no means do, as will appear from experiments to be afterwards produced.

Hitherto chemiſts have never been able to obtain the phlogiſton quite pure, and free from every other ſubſtance: for there are but two ways of ſeparating it from a body of which it makes a part; to wit, either by applying ſome other body with which it may unite the moment it quits the former; or elſe by calcining and burning the compound from which you deſire to ſever it. In the former caſe, it is evident that we do not get the phlogiſton by itſelf, becauſe it only paſſes from one combination into another; and in the latter, it is entirely diſſipated in the decompoſition, ſo that no part of it can poſſibly be ſecured.

The inflammability of a body is an infallible ſign that it contains a phlogiſton; but from a body's not being inflammable, it cannot be inferred that it contains none; for experiments have demonſtrated, that certain metals abound with it, which yet are by no means inflammable.

We have now delivered what is moſt neceſſary to be known concerning the principles of bodies in general. They have many other properties beſides thoſe abovementioned; but we cannot properly take notice of them here, becauſe they preſuppoſe an acquaintance with ſome other things relating to bodies, of which we have hitherto ſaid nothing, intending to treat of them in the ſequel as occaſion ſhall offer. We ſhall only obſerve in this place, that

that when animal and vegetable matters are burnt in ſuch a manner as to hinder them from flaming, ſome part of the phlogiſton contained in them unites intimately with their moſt fixed earthy parts, and with them forms a compound that can be conſumed only by making it red-hot in the open air, where it ſparkles and waſtes away, without emitting any flame. This compound is called a *coal*. We ſhall inquire into the properties of this coal under the head of oils: at preſent it ſuffices that we know in general what it is, and that it readily communicates to other bodies the phlogiſton it contains.

A general View of the Affinities or elective Attractions that ſubſiſt between Bodies.

Before we can reduce compound bodies to the firſt principles above pointed out, we obtain, by analyſing them, certain ſubſtances which are indeed more ſimple than the bodies they helped to compoſe, yet are themſelves compoſed of our primary principles. They are therefore at one and the ſame time both principles and compounds; for which reaſon we ſhall call them by the name of ſecondary principles. Saline and oily matters chiefly conſtitute this claſs. But before we enter upon an examination of their properties, it is fit we lay before the reader a general view of what chemiſts underſtand by the relations or affinities of bodies; becauſe it is neceſſary to know theſe, in order to a diſtinct conception of the different combinations we are to treat of.

All the experiments hitherto made concur in proving, that different bodies, whether principles or compounds, have ſuch a mutual conformity, relation, affinity, or attraction, as diſpoſes ſome of them to join and unite together, while they are incapable of contracting any union with others. This effect, whatever be its cauſe, will enable us to account for, and connect together, all the phenomena that chemiſtry produces. The nature of this univerſal affection of matter is laid down in the following propoſitions.

Firſt, If one ſubſtance has any affinity or conformity with another, the two will unite together, and form one compound.

Secondly, All ſimilar ſubſtances have an affinity with each other, and are conſequently diſpoſed to unite; as water with water, earth with earth, *&c.*

Thirdly, Subſtances that unite together loſe ſome of their ſeparate properties; and the compounds reſulting from their union partake of the properties of thoſe ſubſtances which ſerve as their principles.

Fourthly, The ſimpler any ſubſtances are, the more perceptible and conſiderable are their affinities: whence it follows, that the leſs bodies are compounded, the more difficult it is to analyſe them; that is, to ſeparate from each other the principles of which they conſiſt.

Fifthly, If a body conſiſt of two ſubſtances, and to this compound be preſented a third ſubſtance that has no affinity at all with one of the two primary ſubſtances aforeſaid, but has a greater affinity with the other than thoſe two ſubſtances have with each other, there will enſue a decompoſition, and a new union; that is, the third ſubſtance will ſeparate the two compounding ſubſtances from each other, coaleſce with that which has an affinity with it, form therewith a new combination, and diſengage the other, which will then be left at liberty, and ſuch as it was before it had contracted any union.

Sixthly, It happens ſometimes that when a third ſubſtance is preſented to a body conſiſting of two ſubſtances, no decompoſition follows; but the two compounding ſubſtances, without quitting each other, unite with the ſubſtance preſented to them, and form a combination of three principles: and this happens when that third ſubſtance has an equal, or nearly equal, affinity with each of the compounding ſubſtances. The ſame thing may alſo happen even when the third ſubſtance hath no affinity but with one of the compounding ſubſtances only. To produce ſuch an effect, it is ſufficient that one of the two compounding ſubſtances have to the third body a relation equal, or nearly equal, to that which it has to the other compounding ſubſtance with which it is already combined. Hence it follows, that two ſubſtances, which, when apart from all others, are incapable of contracting any union, may be rendered capable of incorporating together in ſome meaſure, and becoming parts of the ſame compound, by combining with a third ſubſtance with which each of them has an equal affinity.

Seventhly, A body, which of itſelf cannot decompoſe a compound conſiſting of two ſubſtances, becauſe they have a greater affinity with each other than it has with either of them, becomes nevertheleſs capable of ſeparating the two by uniting with one of them, when it is itſelf combined with another body having a degree of affinity with that one ſufficient to compenſate its own want thereof. In that caſe there are two affinities, and thence enſues a double decompoſition, and a double combination.

Theſe fundamental truths, from which we ſhall deduce an explanation of all the phenomena in chemiſtry, will be confirmed and illuſtrated by applying them to the ſeveral caſes, of which our deſign in this treatiſe obliges us to give a circumſtantial account.

Of Saline Subſtances in general.

If a particle of water be intimately united with a particle of earth, the reſult will be a new compound, which, according to our third propoſition of affinities, will partake of the properties of earth and of water; and this combination principally forms what is called a *ſaline ſubſtance*. Conſequently every ſaline ſubſtance muſt have an affinity with earth and with water, and be capable of uniting with both or either of them, whether they be ſeparate or mixed together: and accordingly this property characteriſes all ſalts or ſaline ſubſtances in general.

Water being volatile, and earth fixed, ſalts in general are leſs volatile than the former, and leſs fixed than the latter; that is, fire, which cannot volatilize and carry off pure earth, is capable of rarefying and volatilizing a ſaline ſubſtance; but then this requires a greater degree of heat than is neceſſary for producing the ſame effects on pure water.

There are ſeveral ſorts of ſalts, differing from one another in reſpect either of the quantity or the quality of the earth

earth in their compofition; or, laftly, they differ on account of fome additional principles, which not being combined with them in fufficient quantity to hinder their faline properties from appearing, permit them to retain the name of falts, though they render them very different from the fimpleft faline fubftances.

It is eafy to infer from what has been faid of falts in general, that fome of them muft be more, fome lefs, fixed or volatile than others, and fome more, fome lefs, difpofed to unite with water, with earth, or with particular forts of earth, according to the nature or the proportion of their principles.

Before we proceed further, it is proper juft to mention the principal reafons which induce us to think that every faline fubftance is actually a combination of earth and water, as we fuppofed at our entering on this fubject. The firft is, the conformity falts have with earth and water, or the properties they poffefs in common with both. Of thefe properties we fhall treat fully, as occafion offers to confider them, in examining the feveral forts of falts. The fecond is, that all falts may be actually refolved into earth and water by fundry proceffes; particularly by repeated diffolution in water, evaporation, deficcation, and calcination. Indeed the chemifts have not yet been able to produce a faline fubftance by combining earth and water together. This favours a fufpicion, that befides thefe two there is fome other principle in the compofition of falts which efcapes our refearches, becaufe we cannot preferve it when we decompofe them: but it is fufficient to our purpofe, that water and earth are demonftrably amongft the real principles of faline fubftances, and that no experiment hath ever fhewn us any other.

Of ACIDS.

THE fimpleft faline fubftance is that called an *acid*, on account of its tafte, which is like that of verjuice, forrel, vinegar, and other four things, which for the fame reafon are alfo called acids. By this peculiar tafte are acids chiefly known. They have moreover the property of turning all the blue and violet colours of vegetables red, which diftinguifhes them from all other falts.

The form under which acids moft commonly appear, is that of a tranfparent liquor; though folidity is rather their natural ftate. This is owing to their affinity with water; which is fo great, that, when they contain but juft as much of it as is neceffary to conftitute them falts, and confequently have a folid form, they rapidly unite therewith the moment they come into contact with it: and as the air is always loaded with moifture and aqueous vapours, its contact alone is fufficient to liquify them; becaufe they unite with its humidity, imbibe it greedily, and by that means become fluid. We therefore fay, they attract the moifture of the air. This change of a falt from a folid to a fluid ftate, by the fole contact of the air, is alfo called *deliquium;* fo that when a falt changes in this manner from a folid into a fluid form, it is faid to run *per deliquium*. Acids being the fimpleft fpecies of faline bodies, their affinities with different fubftances are ftronger than thofe of any other fort of falt with the fame fubftances; which is agreeable to our fourth propofition concerning affinities.

Acids in general have a great affinity with earths: that with which they moft readily unite is the unvitrifiable earth to which we gave the name of abforbent earth. They feem not to act at all upon vitrifiable earths, fuch as fand; nor yet upon fome other kinds of earths, at leaft while they are in their natural ftate. Yet the nature of thefe earths may be in fome meafure changed, by making them red hot in the fire, and then quenching them fuddenly in cold water: for by repeating this often they are brought nearer to the nature of abforbent earths, and rendered capable of uniting with acids.

When an acid liquor is mixed with an abforbent earth, for inftance with chalk, thefe two fubftances inftantly rufh into union with fo much impetuofity, that a great ebullition is immediately produced, attended with confiderable hiffing, heat, and vapours, which rife the very inftant of their conjunction.

From the combination of an acid with an abforbent earth there arifes a new compound, which fome chemifts have called *fal falfum;* becaufe the acid by uniting with the earth lofes its four tafte, and acquires another not unlike that of the common fea-falt ufed in our kitchens; yet varying according to the different forts of acids and earths combined together. The acid at the fame time lofes its property of turning blue or violet vegetables red.

If we inquire what is become of its propenfity to unite with water, we fhall find that the earth, which of itfelf is not foluble in water, hath by its union with the acid acquired a facility of diffolving therein; fo that our *fal falfum* is foluble in water. But, on the other hand, the acid hath, by its union with the earth, loft part of the affinity it had with water; fo that if a *fal falfum* be dried, and freed of all fuperfluous humidity, it will remain in that dry folid form, inftead of attracting the moifture of the air and running *per deliquium*, as the acid would do if it were pure and unmixed with earth.

Acids have likewife a great affinity with the phlogifton. When we come to treat of each acid in particular, we fhall examine the combinations of each with the phlogifton: they differ fo widely from one another, and many of them are fo little known, that we cannot at prefent give any general idea of them.

Of ALKALIS.

ALKALIS are faline combinations in which there is a greater proportion of earth than in acids. The principal arguments that may be adduced to prove this fact are thefe: Firft, if they be treated in the manner propofed above for analyfing faline fubftances, we obtain from them a much greater quantity of earth than we do from acids. Secondly; by combining certain acids with certain earths we can produce alkalis; or at leaft fuch faline compounds as greatly refemble ahem. Our third and laft argument is drawn from the properties of thofe alkalis which, when pure and unadulterated with any other principle, have lefs affinity with water than acids have, and are alfo more fixed, refifting the utmoft force of fire. On this account it is that they have obtained the title of *fixed*, as well as to diftinguifh them from another fpecies of alkali, to be confidered hereafter, which is impure and volatile.

Though

Though fixed alkalis, when dry, ſuſtain the utmoſt violence of fire without flying off in vapours, it is remarkable that, being boiled with water in an open veſſel, conſiderable quantities of them riſe with the ſteam; an effect which muſt be attributed to the great affinity between theſe two ſubſtances, by means whereof water communicates ſome part of its volatility to the fixed ſalt.

Alkalis freed of their ſuperfluous humidity by calcination attract the moiſture of the air, but not ſo ſtrongly as acids: ſo that it is eaſier to procure and preſerve them in a ſolid form.

They flow in the fire, and are then capable of uniting with vitrifiable earths, and of forming therewith true glaſs; which, however, will partake of their properties, if they be uſed in ſufficient quantity.

As they melt more readily than vitrifiable earth, they facilitate its fuſion; ſo that a weaker fire will reduce it to glaſs when a fixed alkali is joined with it, than will melt it without that addition.

Alkalis are known by their taſte, which is acrid and fiery; and by the properties they poſſeſs of turning blue or violet vegetables green; particularly ſyrup of violets.

Their affinity with acids is greater than that of abſorbent earths; hence, if an alkali be preſented to a combination of an acid wirh an abſorbent earth, the earth will be ſeparated from the acid by the alkali, and a new union between the acid and the alkali will take place. This is both an inſtance and a proof of our fifth propoſition concerning affinities.

If a pure alkali be preſented to a pure acid, they ruſh together with violence, and produce the ſame phenomena as were obſerved in the union of an abſorbent earth with an acid, but in a greater and more remarkable degree.

Fixed alkalis may in general be divided into two ſorts: one of theſe hath all the above recited properties; but the other poſſeſſes ſome that are peculiar to itſelf. We ſhall conſider this latter ſort more particularly under the head of ſea-ſalt.

Of Neutral Salts.

The acid and the alkali thus uniting, mutually rob each other of their characteriſtic properties; ſo that the compound reſulting from their union produces no change in the blue colours of vegetables, and has a taſte which is neither ſour nor acrid, but ſaltiſh. A ſaline combination of this kind is for that reaſon named *ſal ſalſum, ſal medium*, or a *neutral ſalt*.

It muſt be obſerved, that in order to make theſe ſalts perfectly neutral, it is neceſſary that neither of the two ſaline principles of which they are compounded be predominant over the other; for in that caſe they will have the properties of the prevailing principle. The reaſon is this: neither of theſe ſaline ſubſtances can unite with the other but in a limited proportion, beyond which there can be no further coalition between them. The action by which this perfect union is accompliſhed is termed *ſaturation;* and the inſtant when ſuch proportions of the two ſaline ſubſtances are mixed together, that the one is incorporated with as much of the other as it can poſſibly take up, is called the *point of ſaturation*.

The point of ſaturation is known to be obtained, when, after repeated affuſions of an acid in ſmall quantities to an alkali, or an abſorbent earth, we find thoſe phenomena ceaſe, which in ſuch caſes conſtantly attend the conflict of union, namely, ebullition, hiſſing, *&c.* and we may be aſſured the ſaturation is complete when the new compound hath neither an acid nor an acrid taſte, nor in the leaſt changes the blue colours of vegetables.

Neutral ſalts have not ſo great an affinity with water as either acids or alkalis have, becauſe they are more compounded; for we obſerved before, that the affinities of the moſt compounded bodies are generally weaker than thoſe of the moſt ſimple. In conſequence hereof few natural ſalts, when dried, attract the moiſture of the air; and thoſe that do, attract it more ſlowly and in leſs quantity than either acids or alkalis do.

All neutral ſalts are ſoluble it water; but more or leſs readily, and in a greater or ſmaller quantity, according to the nature of their component principles.

Water made boiling hot diſſolves a greater quantity of thoſe ſalts which do not attract the moiſture of the air, than when it is cold; and indeed it muſt be boiling hot to take up as much of them as it is capable of diſſolving: but as for thoſe which run in the air, the difference is imperceptible.

Some neutral ſalts have the property of ſhooting into cryſtals, and others have it not.

The nature of cryſtallization is this: Water cannot diſſolve, nor keep in ſolution, more than a determinate quantity of any particular ſalt; when therefore ſuch a quantity of water is evaporated from the ſolution of a ſalt capable of cryſtallization, that the remainder contains juſt as much ſalt as it can diſſolve, then by continuing the evaporation the ſalt gradually recovers its ſolid form, and concretes into ſeveral little tranſparent maſſes called cryſtals. Theſe cryſtals have regular figures, all differing from one another according to the ſpecies of ſalt of which they are formed. Different methods of evaporating ſaline ſolutions have different effects on the figure and regularity of the cryſtals; and each particular ſort of ſalt requires a peculiar method of evaporation to make its cryſtals perfectly regular.

A ſolution of ſalt deſigned for cryſtallization is uſually evaporated by means of fire to a pellicle; that is, till the ſalt begin to concrete; which is perceived by a kind of thin dark ſkin that gathers on the ſurface of the liquor, and is formed of the cryſtallized particles of ſalt. When this pellicle appears, the ſolution is ſuffered to cool, and the cryſtals form therein faſter or ſlower according to the ſort of ſalt in hand. If the evaporation be carried on briſkly to perfect drineſs, no cryſtals will be formed, and only an irregular maſs of ſalt will be obtained.

The reaſons why no cryſtals appear when the evaporation is haſtily performed, and carried on to drineſs, are, firſt, that the particles of ſalt, being always in motion while the ſolution is hot, have not time to exert their mutual affinities, and to unite together as cryſtallization requires: ſecondly, that a certain quantity of water enters into the very compoſition of cryſtals; which is therefore abſolutely neceſſary to their formation, and in a

greater

greater or fmaller proportion according to the nature of the falt.

If thefe cryftalized falts be expofed to the fire, they firft part with that moifture which is not neceffary to a faline concretion, and which they retained only by means of their cryftallization: afterwards they begin to flow, but with different degrees of fufibility.

It muft be obferved, that certain falts melt as foon as they are expofed to the fire; namely, thofe which retain a great deal of water in cryftallizing. But this fluor which they fo readily acquire muft be carefully diftinguifhed from actual fufion; for it is owing only to their fuperfluous humidity, which heat renders capable of diffolving and liquifying them; fo that when it is evaporated, the falt ceafes to be fluid, and requires a much greater degree of fire to bring it into real fufion.

The neutral falts that do not cryftallize may indeed be dried by evaporating the water which keeps them fluid; but by becoming folid they acquire no regular form; they again attract the moifture of the air, and are thereby melted into a liquor. Thefe may be called *liquefcent falts*.

Moft of the neutral falts, that confift of an acid joined with a fixed alkali, or with an abforbent earth, are themfelves fixed and refift the force of fire; yet feveral of them, if they be diffolved in water, and the folution boiled and evaporated, flie off along with the fteams.

Of the feveral Sorts of Saline Subftances.

1. *Of the* Universal, *or* Vitriolic Acid.

The univerfal acid is fo called, becaufe it is in fact the acid which is moft univerfally diffufed through all nature, in waters, in the atmofphere, and in the bowels of the earth. But it is feldom pure; being almoft always combined with fome other fubftance. That from which we obtain it, with moft eafe, and in the greateft quantity, is vitriol; and this is the reafon why it is called the *vitriolic acid*; the name by which it is beft known.

When the vitriolic acid contains but little phlegm, yet enough to give it a fluid form, it is called *oil of vitriol;* on account of a certain unctuofity belonging to it.

If the vitriolic acid contain much water, it is then called *fpirit of vitriol.* When it does not contain enough to render it fluid, and fo is in a folid form, it is named the *icy oil of vitriol.*

When oil of vitriol, highly concentrated, is mixed with water, they rufh into union with fuch an impetuofity, that, the moment they touch each other, there arifes a hiffing noife, like that of red-hot iron plunged in cold water, together with a very confiderable degree of heat proportioned to the degree in which the acid was concentrated.

If inftead of mixing this concentrated acid with water, you only leave it expofed to the air for fome time, it attracts the moifture thereof, and imbibes it moft greedily. Both its bulk and its weight are increafed by this acceffion; and if it be under an icy form, that is, if it be concreted, the phlegm thus acquired will foon refolve it into fluid.

The addition of water renders the vitriolic acid, and indeed all other acids, weaker in one fenfe; which is, that when they are very aqueous, they leave on the tongue a much fainter tafte of acidity, and are lefs active in the folution of fome particular bodies: But that occafions no change in the ftrength of their affinities, but in fome cafes rather enables them to diffolve feveral fubftances which, when well dephlegmated, they are not capable of attacking.

The vitriolic acid combined to the point of faturation with a particular abforbent earth, well known, forms a neutral falt that cryftallizes. This falt is called *alum*, and the figure of its cryftals is that of an octahedron or folid of eight fides. Thefe octahedra are triangular pyramids, the angles of which are fo cut off that four of the furfaces are hexagons, and the other four triangles.

There are feveral forts of alum, which differ according to the earths combined with the vitriolic acid. Alum diffolves eafily in water, and in cryftallization retains a confiderable quantity of it; which is the reafon that being expofed to the fire it readily melts, fwelling and puffing up as its fuperfluous moifture exhales. When that is quite evaporated, the remainder is called *burnt alum*, and is very difficult to fufe. The acid of the alum is partly diffipated by this calcination. Its tafte is faltifh, with a degree of roughnefs and aftringency.

The vitriolic acid combined with certain earths forms a kind of neutral falt called *felenites*, which cryftallizes in different forms according to the nature of its earth. There are numberlefs fprings of water infected with diffolved felenites; but when this falt is once cryftallized, it is exceeding difficult to diffolve it in water a fecond time. For that purpofe a very great quantity of water is neceffary, and moreover it muft boil; for, as it cools, moft of the diffolved felenites takes a folid form, and falls in a powder to the bottom of the veffel.

If an alkali be prefented to the felenites, or to alum, thefe falts will be thereby decompofed; that is, the acid will quit the earths, and join the alkali, with which it hath a greater affinity. And from this conjunction of the vitriolic acid with a fixed alkali there refults another fort of neutral falt, which is called *arcanum duplicatum*, *fal de duobus*, and *vitriolated tartar*, becaufe one of the fixed alcalis moft in ufe is called *falt of tartar*.

Vitriolated tartar is almoft as hard to diffolve in water as the felenites. It fhoots into eight-fided cryftals, having the apices of the pyramids pretty obtufe. Its tafte is faltifh, inclining to bitter; and it decrepitates on burning coals. It requires a very great degree of fire to make it flow.

The vitriolic acid is capable of uniting with the phlogifton, or rather it has a greater affinity with it than with any other body: whence it follows, that all compounds of which it makes a part may be decompofed by means of the phlogifton.

From the conjunction of the vitriolic acid with the phlogifton arifes a compound called *mineral fulphur*, becaufe it is found perfectly formed in the bowels of the earth. It is alfo called *fulphur vivum*, or fimply *fulphur*.

Sulphur

Sulphur is absolutely insoluble in water, and incapable of contracting any sort of union with it. It melts with a very moderate degree of heat, and sublimes in fine light downy tufts called *flowers of sulphur*. By being thus sublimed it suffers no decomposition, let the operation be repeated ever so often; so that sublimed sulphur, or flower of sulphur, hath exactly the same properties as sulphur that has never been sublimed.

If sulphur be exposed to a brisk heat in the open air, in takes fire, burns, and is wholly consumed. This deflagration of sulphur is the only means we have of decomposing it, in order to obtain its acid in purity. The phlogiston is destroyed by the flame, and the acid exhales in vapours; these vapours collected have all the properties of the vitriolic acid, and differ from it only as they still retain some portion of the phlogiston; which, however, soon quits them of its own accord, if the free access of the common air be not precluded.

The portion of phlogiston retained by the acid of sulphur is much more considerable when that mineral is burnt gradually and slowly: in that case the vapours which rise from it have such a penetrating odour, that they instantaneously suffocate any person who draws in a certain quantity of them with his breath. These vapours constitute what is called the *volatile spirit of sulphur*. There is reason to think this portion of phlogiston which the acid retains is combined therewith in a manner different from that in which these two are united in the sulphur itself; for nothing but actual burning is capable of separating the vitriolic acid and the phlogiston, which by their union form sulphur; whereas in the volatile spirit of sulphur they separate spontaneously when exposed to the open air; that is, the phlogiston flies off and leaves the acid, which then becomes in every respect similar to the vitriolic acid.

That the volatile spirit of sulphur is a compound, appears evidently from hence, that whenever the vitriolic acid touches any substance containing the phlogiston, provided that phlogiston be disengaged or opened to a certain degree, a volatile spirit of sulphur is infallibly and immediately generated. This spirit hath all the properties of acids, but considerably weakened, and of course less perceptible. It unites with absorbent earths or fixed alkalis; and with them forms neutral salts: but when combined therewith it may be separated from them by the vitriolic acid, and indeed by any of the mineral acids, because its affinities are weaker. Sulphur hath the property of uniting with absorbent earths, but not near so intimately as with fixed alkalis.

If equal parts of sulphur and an alkali be melted together, they incorporate with each other; and from their conjunction proceeds a compound of a most unpleasant smell, much like that of rotten eggs, and of a red colour nearly resembling that of an animal liver, which has occasioned it to bear the name of *hepar sulphuris*, or *liver of sulphur*.

In this composition the fixed alkali communicates to the sulphur the property of dissolving in water: and hence it comes that liver of sulphur may be made as well when the alkali is dissolved by water into a fluid, as when it is fused by the action of fire.

Sulphur has less affinity than any acid with the fixed alkalis: and therefore liver of sulphur may be decompounded by any acid whatever; which will unite with the fixed alkali, form therewith a neutral salt, and separate the sulphur.

If liver of sulphur be dissolved in water, and an acid poured thereon, the liquor, which was transparent before, instantly turns to an opaque white; because the sulphur, being forced to quit its union with the alkali, loses at the same time the property of dissolving in water, and appears again in its own opaque form. The liquor thus made white by the sulphur is called *milk of sulphur*.

If this liquor be suffered to stand still for some time, the particles of sulphur, now most minutely divided, gradually approach each other, unite, and fall insensibly to the bottom of the vessel; and then the liquor recovers its transparency. The sulphur thus deposited on the bottom of the vessel is called the *magistery* or *precipitate sulphur*. The names of magistery and precipitate are also given to all substances whatever that are separated from another by this method; which is the reason that we use the expression of precipitating one substance by another, to signify the separating one of them by means of the other.

3. *Of the* Nitrous Acid.

The nitrous acid combined with certain absorbent earths, such as chalk, marle, boles, forms neutral salts which do not crystallize; and which, after being dried, run in the air *per deliquium*.

All those neutral salts which consist of the nitrous acid joined to an earth, may be decomposed by a fixed alkali, with which the acid unites, and deserts the earth; and from this union of the nitrous acid with a fixed alkali results a new neutral salt, which is called *nitre*, or *salt-petre*. This latter name signifies the *salt of stone*; and in fact, nitre is extracted from the stones and plaister, in which it forms, by boiling them in water saturated with a fixed alkali.

Nitre shoots in long crystals adhering sideways to each other; it has a saltish taste, which produces a sensation of cold on the tongue.

This salt easily dissolves in water; which, when it boils, takes up still a greater quantity thereof.

It flows with a pretty moderate degree of heat, and continues fixed therein: but being urged by a brisk fire, and in the open air, it lets go some part of its acid, and indeed flies off itself in part.

The most remarkable property of nitre, and that which characterizes it, is its fulmination or explosion; the nature of which is as follows:

When nitre touches any substance containing a phlogiston, and actually ignited, that is, red hot, it bursts out into a flame, burns, and is decompounded with much noise.

In this deflagration the acid is dissipated, and totally separated from the alkali, which now remains by itself.

Indeed the acid, at least the greatest part of it, is by this means quite destroyed. The alkali which is left when nitre is decompounded by deflagration, is called in general

general *fixed nitre*, and, more particluarly, nitre fixed by ſuch and ſuch a ſubſtance as was uſed in the operation. But if nitre be deflagrated with an inflammable ſubſtance containing the vitriolic acid, as ſulphur, for inſtance, the fixed ſalt produced by the deflagration is not a pure alkali but retains a good deal of the vitriolic acid, and, by combining therewith, hath now formed a neutral ſalt.

The reaſon why nitre flames, and is decompounded in the manner above mentioned, when it comes in contact with a phlogiſton properly circumſtanced, is, that the nitrous acid, having a greater affinity with the phlogiſton than with the fixed alkali, naturally quits the latter to join with the former, and ſo produces a kind of ſulphur, differing probably from the common ſulphur, formed by the vitriolic acid, in that it is combuſtible to ſuch a degree, as to take fire and be conſumed in the very moment of its production; ſo that it is impoſſible to prevent its being thus deſtroyed, and conſequently impoſſible to ſave it. In ſupport of this opinion let it be conſidered, that the concurrence of the phlogiſton is abſolutely neceſſary to produce this deflagration, and that the matter of pure fire is altogether incapable of effecting it: for though nitre be expoſed to the moſt violent degree of fire, even that in the focus of the moſt powerful burning-glaſs, it will not flame; nor will that effect ever happen till the nitre be brought into contact with a phlogiſton properly ſo called, that is, the matter of fire exiſting as a principle of ſome body; and it is moreover neceſſary that this phlogiſton be actually on fire, and agitated with the igneous motion, or elſe, that the nitre itſelf be red-hot, and ſo penetrated with fire as to kindle any inflammable matter that touches it.

This experiment, among others, helps to ſhew the diſtinction that ought to be made between pure elementary fire, and fire become a principle of bodies to which we have given the name of phlogiſton.

Before we leave this ſubject, we ſhall obſerve, that nitre deflagrates only with ſuch ſubſtances as contain the phlogiſton in its ſimpleſt and pureſt form; ſuch as charcoal, ſulphur, and the metalline ſubſtances; and that, though it will not deflagrate without the addition of ſome combuſtible matter, it is neverthels the only known body that will burn, and make other combuſtibles burn with it, in cloſe veſſels, without the admiſſion of freſh air.

The nitrous acid hath not ſo great an affinity with earths and alkalis as the vitriolic acid hath; whence it follows, that the vitriolic acid decompoſes all neutral ſalts ariſing from a combination of the nitrous acid with an earth or an alkali. The vitriolic acid expells the nitrous acid, unites with the ſubſtance which ſerved it for a baſis, and therewith forms a neutral ſalt, which is an alum, a ſelenites, or a vitriolated tartar, according to the nature of that baſis.

The nitrous acid, when thus ſeparated from its baſis by the vitriolic acid, is named *ſpirit of nitre*, or *aqua fortis*. If it be dephlegmated, or contain but little ſuperfluous water, it exhales in reddiſh vapours; theſe vapours being condenſed and collected, form a liquor of a browniſh yellow, that inceſſantly emits vapours of the ſame colour, and of a pungent diſagreeable ſmell. Theſe characters have procured it the names of *ſmoking ſpirit of nitre*, and *yellow aqua fortis*. This property in the nitrous acid of exhaling in vapours, ſhews it to be leſs fixed than the vitriolic acid; for the latter, though ever ſo thoroughly dephlegmated, never yields any vapours, nor has it any ſmell.

3. *Of the* Acid *of* Sea-salt.

The acid of ſea-ſalt is ſo called, becauſe it is in fact obtained from ſuch ſea-ſalt as is uſed in our kitchens. It is not certainly known in what this acid differs from the vitriolic and the nitrous, with regard to its conſtituent parts.

When it is combined with abſorbent earths, ſuch as lime and chalk, it forms a neutral ſalt that does not cryſtallize; and, when dried, attracts the moiſture of the air. If the abſorbent earth be not fully ſaturated with the marine acid, the ſalt thereby formed has the properties of a fixed alkali: And this is what made us ſay, when we were on the ſubject of thoſe ſalts that they might be imitated by combining an earth with an acid. The marine acid, like the reſt, hath not ſo great an affinity with earths as with fixed alkalis.

When it is combined with the latter, it forms a neutral ſalt which ſhoots into cubical cryſtals. This ſalt is inclined to grow moiſt in the air, and is conſequently one of thoſe which water diſſolves in equal quantities, at leaſt as to ſenſe, whether it be boiling hot or quite cold.

The affinity of this acid with alkalis and abſorbent earths is not ſo great as that of the vitriolic and nitrous acids: Whence it follows, that, when combined therewith, it may be ſeparated from them by either of thoſe acids.

The acid of ſea-ſalt, thus diſengaged from the ſubſtance which ſerved it for a baſis, is called *ſpirit of ſalt*. When it contains but little phlegm, it is of a lemon colour, and continually emits many white, very denſe, and very elaſtic vapours; on which account it is named the *ſmoking or volatile ſpirit of ſalt*. Its ſmell is not diſagreeable, nor much unlike that of ſaffron; but extremely quick and ſuffocating when it ſmokes.

The acid of ſea-ſalt, like the other two, ſeems to have a greater affinity with the phlogiſton, than with fixed alkalis. We are led to this opinion by a very curious operation, which gives ground to think, that ſea-ſalt may be decompoſed by the proper application of a ſubſtance containing the phlogiſton.

From the marine acid, combined with a phlogiſton, reſults a kind of ſulphur, differing from the common ſort in many reſpects; but particularly in this property, that it takes fire of itſelf upon being expoſed to the open air. This combination is called *Engliſh phoſphorus*, *phoſphorus of urine*, becauſe it is generally prepared from urine, or only *phoſphorus*.

This combination of the marine acid with a phlogiſton is not eaſily effected; becauſe it requires a difficult operation in appropriated veſſels. For theſe reaſons it does not always ſucceed; and phoſphorus is ſo ſcarce and dear, that hitherto chemiſts have not been able to make on it the experiments neceſſary to diſcover all its properties. If phoſphorus be ſuffered to burn away in the air, a

a ſmall quantity of an acid liquor may be obtained from it, which ſeems to be ſpirit of ſalt, but either altered, or combined with ſome adventitious matter; for it has ſeveral properties that are not to be found in the pure marine acid; ſuch as, leaving a fixed fuſible ſubſtance behind it when expoſed to a ſtrong fire, and being eaſily combined with the phlogiſton ſo as to reproduce a phoſphorus.

Phoſphorus reſembles ſulphur in ſeveral of its properties: It is ſoluble in oils; it melts with a gentle heat; it is very combuſtible; it burns without producing ſoot; and its flame is vivid and bluiſh.

From what has been ſaid of the union of the acid of ſea-ſalt with a fixed alkali, and of the neutral ſalt reſulting therefrom, it may be concluded, that this neutral ſalt is no other than the common kitchen-ſalt. But it muſt be obſerved, that the fixed alkali, which is the natural baſis of the common ſalt obtained from ſea-water, is of a ſort ſomewhat differing from fixed alkalis in general, and hath certain properties peculiar to itſelf. For,

1. The baſis of ſea-ſalt differs from other fixed alkalis in this, that it cryſtallizes like a neutral ſalt.

2. It does not grow moiſt in the air: On the contrary, when expoſed to the air, it loſes part of the water that united with it in cryſtallization, by which means its cryſtals loſe their tranſparency, become as it were mealy, and fall into a fine flour.

3. When combined with the vitriolic acid to the point of ſaturation, it forms a neutral ſalt differing from vitriolated tartar, firſt, in the figure of its cryſtals which are oblong ſix-ſided ſolids; ſecondly, in its quantity of water, which in cryſtallization unites therewith in a much greater proportion than with vitriolated tartar; whence it follows, that this ſalt diſſolves in water more readily than vitriolated tartar; thirdly, in that it flows with a very moderate degree of heat, whereas vitriolated tartar requires a very fierce one.

If the acid of ſea-ſalt be ſeparated from its baſis by means of the vitriolic acid, it is eaſy to ſee, that, when the operation is finiſhed, the ſalt we have been ſpeaking of muſt be the reſult. A famous chemiſt, named Glauber, was the firſt who extracted the ſpirit of ſalt in this manner, examined the neutral ſalt reſulting from his proceſs, and finding it to have ſome ſingular properties, called it his *ſal mirabile*, or wonderful ſalt: On this account it is ſtill called Glauber's *ſal mirabile*, or *Glauber's ſalt*.

4. When the baſis of the ſea-ſalt is combined with the nitrous acid to the point of ſaturation, there reſults a neutral ſalt, or a ſort of nitre, differing from the common nitre, firſt, in that it attracts the moiſture of the air pretty ſtrongly; and this makes it difficult to cryſtallize: ſecondly, in the figure of its cryſtals, which are parallelopipeds; and this has procured it the name of *quadrangular nitre*.

Common ſalt, or the neutral ſalt formed by combining the marine acid with this particular ſort of fixed alkali, has a taſte well known to every body. The figure of its cryſtals is exactly cubical. It grows moiſt in the air, and, when expoſed to the fire, it burſts, before it melts, into many little fragments, with a crackling noiſe; which is called the *decrepitation* of ſea-ſalt.

That neutral ſalt mentioned above, which is formed by combining the marine acid with a common fixed alkali, and called *ſal febrifugum ſylvii*, hath alſo this property.

India furniſhes us with a ſaline ſubſtance, known by the name of *borax*, which flows very eaſily, and then takes the form of glaſs. It is of great uſe in facilitating the fuſion of metallic ſubſtances. It poſſeſſes ſome of the properties of fixed alkalis, which has induced certain chemiſts to repreſent it, through miſtake, as a pure fixed alkali.

By mixing borax with the vitriolic acid, Mr Homberg obtained from it a ſalt, which ſublimes in a certain degree of heat, whenever ſuch a mixture is made. This ſalt has very ſingular properties; but its nature is not yet thoroughly underſtood. It diſſolves in water with great difficulty; it is not volatile, though it riſes by ſublimation from the borax. According to Mr Rouelle's obſervation, it riſes then only by means of the water which carries it up; for when once made, it abides the fierceſt fire, flows and vitrifies juſt as borax does, provided care be taken to free it previouſly from moiſture by drying it properly. Mr Homberg called it *ſedative ſalt*, on account of its medical effects. The ſedative ſalt hath the appearance, and ſome of the properties, of a neutral ſalt; for it ſhoots into cryſtals, and does not change the colour of violets: but it acts the part of an acid with regard to alkalis, uniting with them to the point of ſaturation, and thereby forming a true neutral ſalt. It alſo acts, like the acid of vitriol, on all neutral ſalts; that is, it diſcharges the acid of ſuch as have not the vitriolic acid in their compoſition.

Since Mr Homberg's time it hath been diſcovered, that a ſedative ſalt may be made either with the nitrous or with the marine acid; and that ſublimation is not neceſſary to extract it from the borax, but that it may be obtained by cryſtallization only. For this latter diſcovery we are indebted to Mr Geoffroy, as we are to Mr Lemery for the former.

Since that time M. Baron d'Henouville, an able chemiſt, hath ſhewn that a ſedative ſalt may be obtained by the means of vegetable acids; and hath lately demonſtrated, that the ſedative ſalt exiſts actually and perfectly in the borax, and that it is not produced by mixing acids with that ſaline ſubſtance, as it ſeems all the chemiſts before him imagined. This he proves convincingly from his analyſis of borax, (which thereby appears to be nothing elſe but the ſedative ſalt united with that fixed alkali which is the baſis of ſea-ſalt) and from his regenerating the ſame borax by uniting together that alkali and the ſedative ſalt: a proof the moſt complete that can poſſibly be produced in natural philoſophy, and equivalent to demonſtration itſelf.

In order to finiſh what remains to be ſaid upon the ſeveral ſorts of ſaline ſubſtances, we ſhould now ſpeak of the acids obtained from vegetables and animals, and alſo of the volatile alkalis; but, ſeeing theſe ſaline ſubſtances differ from thoſe of which we have already treated, only as

as they are variouſly altered by the unions they have contracted with certain principles of vegetables and animals, of which nothing has been yet ſaid, it is proper to defer being particular concerning them, till we have explained thoſe principles.

Of LIME.

ANY ſubſtance whatever, that has been roaſted a conſiderable time in a ſtrong fire without melting, is commonly called a *calx*. Stones and metals are the principal ſubjects that have the property of being converted into *calces*. We ſhall treat of metalline *calces* in a ſubſequent chapter, and in this confine ourſelves to the *calx* of *ſtone*, known by the name of *lime*.

In treating of earths in general, we obſerved that they may be divided into two principal kinds; one of which actually and properly flows when expoſed to the action of fire, and turns to glaſs; whence it is called a *fuſible* or *vitrifiable* earth; the other reſiſts the utmoſt force of fire, and is therefore ſaid to be an *unfuſible* or *unvitrifiable* earth. The latter is alſo not uncommonly called *calcinable* earth; though ſundry ſorts of unfuſible earths are incapable of acquiring by the action of fire all the qualities of *calcined* earth, or *lime* properly ſo called: ſuch earths are particularly diſtinguiſhed by the denomination of *refractory* earths.

As the different ſorts of ſtones are nothing more than compounds of different earths, they have the ſame properties with the earths of which they are compoſed, and may, like them, be divided into fuſible or vitrifiable, and unfuſible or calcinable. The fuſible ſtones are generally denoted by the name of *flints*; the calcinable ſtones, again, are the ſeveral ſorts of marbles, cretaceous ſtones, thoſe commonly called free-ſtones, *&c.* ſome of which, as they make the beſt lime, are, by way of eminence, called *lime-ſtones*. Sea-ſhells alſo, and ſtones that abound with foſſile ſhells, are capable of being burnt to lime.

All theſe ſubſtances being expoſed for a longer or ſhorter time to the violent action of fire, are ſaid to be *calcined*. By calcination they loſe a conſiderable part of their weight, acquire a white colour, and become friable, though ever ſo ſolid before; as, for inſtance, the very hardeſt marbles. Theſe ſubſtances, when thus calcined, take the name of *quick-lime*.

Water penetrates quick-lime, and ruſhes into it with vaſt activity. If a lump of newly calcined lime be thrown into water, it inſtantly excites almoſt as great a noiſe, ebullition, and ſmoke, as would be produced by a piece of red-hot iron; with ſuch a degree of heat too, that, if the lime be in due proportion to the water, it will ſet fire to combuſtible bodies; as hath unfortunately happened to veſſels laden with quick lime, on their ſpringing a ſmall leak.

As ſoon as quick-lime is put into water, it ſwells, and falls aſunder into an infinite number of minute particles: in a word, it is in a manner diſſolved by the water, which forms therewith a ſort of white paſte called *ſlacked lime*.

If the quantity of water be conſiderable enough for the lime to form with it a white liquor, this liquor is called *lac calcis*; which, being left ſome time to ſettle, grows clear and tranſparent, the lime which was ſuſpended therein and occaſioned its opacity ſubſiding to the bottom of the veſſel. Then there forms on the ſurface of the liquor a cryſtalline pellicle, ſomewhat opaque and dark coloured, which being ſkimmed off is reproduced from time to time. This matter is called *cremor calcis*.

Slacked lime gradually grows dry, and takes the form of a ſolid body, but full of cracks and deſtitute of firmneſs. The event is different when you mix it up, while yet a paſte, with a certain quantity of uncalcined ſtony matter, ſuch as ſand for example: then it takes the name of *mortar*, and gradually acquires, as it grows drier and older, a hardneſs equal to that of the beſt ſtones. This is a very ſingular property of lime, nor is it eaſy to account for it; but it is a beneficial one, for every body knows the uſe of mortar in building.

Quick-lime attracts the moiſture of the air in the ſame manner as concentrated acids and dry fixed alkalis, but not in ſuch quantities as to render it fluid: it only falls into extremely ſmall particles, takes the form of a fine powder, and the title of *lime ſlacked in the air*.

Lime once ſlacked, however dry it may afterwards appear, always retains a large portion of the water it had imbibed; which cannot be ſeparated from it again but by means of a violent calcination. Being ſo recalcined it returns to be quick-lime, recovering all its properties.

Beſides this great affinity of quick-lime with water, which diſcovers a ſaline character, it has ſeveral other ſaline properties, to be afterwards examined, much reſembling thoſe of fixed alkalis. In chemiſtry it acts very nearly as thoſe ſalts do, and may be conſidered as holding the middle rank between a pure abſorbent earth and a fixed alkali; and this hath induced many chemiſts to think that lime contains a true ſalt, to which all the properties it poſſeſſes in common with ſalts may be attributed.

But as the chemical examinatiou of this ſubject hath long been neglected, the exiſtence of a ſaline ſubſtance in lime hath been long doubtful. Mr du Fay was one of the firſt who obtained a ſalt from lime, by lixiviating it with a great deal of water, which he afterwards evaporated. But the quantity of ſalt he obtained by that means was very ſmall; nor was it of an alkaline nature, as one would think it ſhould have been, conſidering the properties of lime. Mr du Fay did not carry his experiments on this ſubject any further, probably for want of time; nor did he determine of what nature the ſalt was.

Mr Malouin had the curioſity to examine this ſalt of lime, and ſoon found that it was nothing elſe but what was above called *cremor calcis*. He found moreover, that, by mixing a fixed alkali with lime-water, a vitriolated tartar was formed; that, by mixing therewith an alkali like the baſis of ſea-ſalt, a Glauber's ſalt was produced; and, laſtly, by combining lime with a ſubſtance abounding in phlogiſton, he obtained a true ſulphur. Theſe very ingenious experiments prove to a demonſtration, that the vitriolic acid conſtitutes the ſalt of lime; for, as hath been ſhewn, no other acid is capable of forming ſuch combi-

combinations. On the other hand, Mr Malouin, having forced the vitriolic acid of this falt to combine with a phlogifton, found its bafis to be earthy, and analogous to that of the felenites: whence he concluded, that the falt of lime is a true neutral falt, of the fame kind as the felenites. Mr Malouin tells us he found feveral other falts in lime. But as none of them was a fixed alkali, and as all the faline properties of lime have an affinity with thofe of that kind of falt, there is great reafon to think that all thofe falts are foreign to lime, and that their union with it is merely accidental.

Lime unites with all acids, and in conjunction with them exhibits various phenomena.

The vitriolic acid poured upon lime diffolves it with effervefcence and heat. From this mixture there exhales a great quantity of vapours, in fmell and colour perfectly like thofe of fea-falt; from which however they are found to be very different when collected into a liquor. From this combination of the vitriolic acid with lime arifes a neutral falt, which fhoots into cryftals, and is of the fame kind with the felenitic falt obtained from lime by Mr Malouin.

The nitrous acid poured upon lime diffolves it in like manner with effervefcence and heat: but the folution is tranfparent, and therein differs from the former, which is opaque. From this mixture there arifes a neutral falt, which does not cryftallize, and has withal the very fingular property of being volatile, and rifing wholly by diftillation in a liquid form. This phenomenon is fo much the more remarkable, as lime, the bafis of this falt, is one of the moft fixed bodies known in chemiftry.

With the acid of fea-falt lime forms alfo a fingular fort of falt, which greedily imbibes the moifture of the air. We fhall have occafion to take further notice of it in another place.

Lime applied to fixed alkalis adds confiderably to their cauftic quality, and makes them more penetrating and active. An alkaline lixivium in which lime hath been boiled, being evaporated to drinefs, forms a very cauftic fubftance, which flows in the fire much more eafily, attracts and retains moifture much more ftrongly, than fixed alkalis that have not been fo treated. An alkali thus acuated by lime is called the *cauftic ftone*, or *potential cautery*, becaufe it is employed by furgeons to produce efchars on the fkin and cauterize it.

Of Metallic Subftances in general.

Metallic fubftances are heavy, glittering, opaque, fufible bodies. They confift chiefly of a vitrifiable earth united with the phlogifton.

Several chemifts infift on a third principle in thefe bodies, and have given it the name of *mercurial earth*; which, according to Becher and Stahl, is the very fame that being combined with the vitriolic acid forms and characterifes the acid of fea-falt. The exiftence of this principle hath not yet been demonftrated by any decifive experiment; but we fhall fhew that there are pretty ftrong reafons for admitting it.

We fhall begin with mentioning the experiments which prove metallic fubftances to confift of a vitrifiable earth united with the phlogifton. The firft is this: if they be calcined in fuch a manner as to have no communication with any inflammable matter, they will be fpoiled of all their properties, and reduced to an earth or calx, that has neither the fplendour nor the ductility of a metal, and in a ftrong fire turns to an actual glafs, inftead of flowing like a metal.

The fecond is, that the calx or the glafs refulting from a metal thus decompofed, recovers all its metalline properties by being fufed in immediate contact with an inflammable fubftance, capable of reftoring the phlogifton of which calcination had deprived it.

On this occafion we muft obferve, that chemifts have not yet been able, by adding the phlogifton, to give the properties of metals to all forts of vitrifiable earths indifcriminately, but to fuch only as originally made a part of fome metallic body. For example, a compound cannot be made with the phlogifton and fand that fhall have the leaft refemblance of a metal: and this is what feems to point out the reality of a third principle as neceffary to form the metalline combination. This principle may probably remain united with the vitrifiable earth of a metallic fubftance, when reduced to a glafs; whence it follows, that fuch vitrified metals require only the addition of a phlogifton to enable them to appear again in their priftine form.

It may be inferred from another experiment, that the calx and the glafs of a metal are not its pure vitrifiable earth, properly fo called: for by repeated or long continued calcinations, fuch a calx or glafs may be rendered incapable of ever refuming the metalline form, in what ever manner the phlogifton be afterwards applied to it; fo that by this means it is brought into the condition of a pure vitrifiable earth, abfolutely free from any mixture.

When by adding the phlogifton to a metallic glafs, we reftore it to the form of a metal, we are faid to *reduce*, *refufcitate*, or *revivify* that metal.

Metallic fubftances are of different kinds, and are divided into *metals* and *femi-metals*.

Thofe are called metals, which befides their metalline fplendor and appearance, are alfo malleable; that is, have the property of ftretching under the hammer.

Thofe which have only the metalline fplendor and appearance, without malleability, are called femi-metals.

Metals alfo are further fubdivided into two forts; *viz. perfect* and *imperfect* metals.

The perfect metals are thofe which fuffer no damage or change whatever by the moft violent and moft lafting action of fire.

The imperfect metals are thofe which by the force of fire may be deprived of their phlogifton, and confequently of their metalline form.

When a moderate degree of fire only is employed to deprive a metal of its phlogifton, the metal is faid to be *calcined*; and then it appears in the form of a powdered earth, which is called a *calx*; and this metalline calx being expofed to a more violent degree of fire, melts and turns to glafs.

Metallic ſubſtances have an affinity with acids, but not equally with all; that is, every metallic ſubſtance is not capable of uniting and joining with every acid.

When an acid unites with a metallic ſubſtance, there commonly ariſes an ebullition, attended with a kind of hiſſing noiſe and fuming exhalations. By degrees, as the union becomes more perfect, the particles of the metal combining with the acid become inviſible: this is termed *diſſolution*; and when a metalline maſs thus diſappears in an acid, the metal is ſaid to be *diſſolved* by that acid. It is proper to obſerve, that acids act upon metalline ſubſtances, in one reſpect, juſt as they do upon alkalis and abſorbent earths: for an acid cannot take up above ſuch a certain proportion thereof as is ſufficient to ſaturate it, to deſtroy ſeveral of its properties, and weaken others. For example, when an acid is combined with a metal to the point of ſaturation, it loſes its taſte, does not turn the blue colour of a vegetable red, and its affinity with water is conſiderably impaired. On the other hand, metalline ſubſtances, which, when pure, are incapable of uniting with water, by being joined with an acid, acquire the property of diſſolving in water. Theſe combinations of metalline ſubſtances with acids form different ſorts of neutral ſalts; ſome of which have the property of ſhooting into cryſtals, while others have it not: moſt of them, when thoroughly dried, attract the moiſture of the air.

The affinity which metalline ſubſtances have with acids is leſs than that which abſorbent earths and fixed alkalis have with the ſame acids; ſo that all metalline ſalts may be decompounded by one of theſe ſubſtances, which will unite with the acid, and precipitate the metal.

Metalline ſubſtances thus ſeparated from an acid ſolvent are called *magiſteries*, and *precipitates* of metals. None of theſe precipitates, except thoſe of the perfect metals, retain the metalline form: moſt of their phlogiſton hath been deſtroyed by the ſolution and precipitation, and muſt be reſtored before they can recover their properties. In ſhort, they are nearly in the ſame ſtate with metalline ſubſtances deprived of their phlogiſton by calcination; and accordingly ſuch a precipitate is called a *calx*.

A metalline calx prepared in this manner loſes a greater or a leſs portion of its phlogiſton, the more or leſs effectually and thoroughly the metalline ſubſtance of which it made a part was diſſolved by the acid.

Metallic ſubſtances have affinities with each other which differ according to their different kinds; but this is not univerſal, for ſome of them are incapable of any ſort of union with ſome others.

It muſt be obſerved, that metallic ſubſtances will not unite, except they be both in a ſimilar ſtate; that is, both in a metalline form, or both in the form of a glaſs; for a metalline ſubſtance, retaining its phlogiſton, cannot contract an union with any metallic glaſs, even its own.

Of METALS.

THERE are ſix metals, of which two are perfect, and four imperfect. The perfect metals are gold and ſilver; the others are copper, tin, lead, and iron. Some chemiſts admit a ſeventh metal, *viz.* quick-ſilver; but, as it is not malleable, it has been generally conſidered as a metallic body of a particular kind.

The ancient chemiſts, or rather the alchemiſts, who fancied a certain relation or analogy between metals and the heavenly bodies, beſtowed on the ſeven metals, reckoning quick ſilver one of them, the names of the ſeven planets of the ancients, according to the affinity which they imagined they obſerved between thoſe ſeveral bodies, Thus gold was called *Sol*, ſilver *Luna*, copper *Venus*. tin *Jupiter*, lead *Saturn*, iron *Mars*, and quick-ſilver *Mercury*. Though theſe names were aſſigned for reaſons merely chimerical, yet they ſtill keep their ground; ſo that it is not uncommon to find the metals called by the names, and denoted by the characters, of the planets, in the writings even of the beſt chemiſts. Metals are the heavieſt bodies known in nature.

Of GOLD.

GOLD is the heavieſt of all metals. The arts of wire-drawing and gold-beating ſhew its wonderful ductility. The greateſt violence of fire is not able to produce any alteration in it.

Gold cannot be diſſolved by any pure acid: but if the acid of nitre be mixed with the acid of ſea-ſalt, there reſults a compound acid liquor, with which it has ſo great an affinity, that it is capable of being perfectly diſſolved thereby. The chemiſts have called this ſolvent *aqua regis*, on account of its being the only acid that can diſſolve gold, which they conſider as the king of metals. The ſolution of gold is of a beautiful orange colour.

If gold diſſolved in *aqua regis* be precipitated by an alkali or an abſorbent earth, the precipitate gently dried, and then expoſed to a certain degree of heat, is inſtantly diſperſed into the air, with a moſt violent exploſion and noiſe: gold thus precipitated is therefore called *aurum fulminans*. But if the precipitated gold be carefully waſhed in plenty of water, ſo as to clear it of all the adhering ſaline particles, it will not fulminate; but may be melted in a crucible without any additament, and will then appear in its uſual form. The acid of vitriol being poured on *aurum fulminans* likewiſe deprives it of its fulminating quality.

Gold does not begin to flow till it be red-hot like a live coal. Though it be the moſt malleable and moſt ductile of all metals, it has the ſingular property of loſing its ductility more eaſily than any of them: even the fumes of charcoal are ſufficient to deprive it thereof, if they come to contact with it while it is in fuſion.

The malleability of this metal, and indeed of all the reſt, is alſo conſiderably diminiſhed by expoſing it ſuddenly to cold when it is red-hot; for example, by quenching it in water, or even barely expoſing it to the cold air. The way to reſtore ductility to gold, when loſt by its coming in contact with the vapour of coals, and in general to every other metal rendered leſs malleable by being ſuddenly cooled, is to heat it again, to keep them red hot a conſiderable time, and then to let them cool very ſlowly and gradually: this operation frequently repeated will by degrees much increaſe the malleability of a metal.

Pure ſulphur hath no effect on gold; but being combined

bined with an alkali into a *hepar ſulphuris*, it unites therewith very readily. Nay, ſo intimate is their union, that the gold by means thereof becomes ſoluble in water; and this new conpound of gold and liver of ſulphur, being diſſolved in water, will paſs through the pores of brown paper without ſuffering any decompoſition; which does not happen, at leaſt in ſuch a manifeſt degree, to other metallic ſubſtances diſſolved by liver of ſulphur.

Aurum fulminans mixed and melted with flour of ſulphur loſes its fulminating quality: which ariſes from hence, that on this occaſion the ſulphur burns, and its acid, which is the ſame with the vitriolic, being thereby ſet at liberty, becomes capable of acting upon the gold as a vitriolic acid would; which, as was ſaid above, deprives the gold of its fulminating quality.

Of Silver.

Next to gold, ſilver is the moſt perfect metal. Like gold, it reſiſts the utmoſt violence of fire, even that in the focus of a burning-glaſs. However, it holds only the ſecond place among metals; becauſe it is lighter than gold by almoſt one half; is alſo ſomewhat leſs ductile; and laſtly, becauſe it is acted upon by a greater number of ſolvents.

Yet ſilver hath one advantage over gold, namely that of being a little harder; which makes it alſo more ſonorous.

This metal, like gold, begins to flow when it is ſo thoroughly penetrated by the fire as to appear ignited like a live coal.

While this metal is in fuſion, the immediate contact of the vapour of burning coals deprives it almoſt entirely of its malleability, in the ſame manner as we obſerved happens to gold: but both theſe metals eaſily recover that property by being melted with nitre.

The nitrous acid is the true ſolvent of ſilver, and being ſomewhat dephlegmated will very readily and eaſily take up a quantity of ſilver equal in weight to itſelf.

Silver thus combined with the nitrous acid forms a metallic ſalt which ſhoots into cryſtals, called by the name of *lunar cryſtals*, or *cryſtals of ſilver*.

Theſe cryſtals are moſt violently cauſtic: applied to the ſkin, they quickly affect it much as a live coal would; they produce a blackiſh eſchar, corroding and entirely deſtroying the parts they touch. Surgeons uſe them to eat away the proud fungous fleſh of ulcers. As ſilver united with the nitrous acid hath the property of blackening all animal ſubſtances, a ſolution of this metallic ſalt is employed to die hair, or other animal matters, of a beautiful and durable black.

Theſe cryſtals flow with a very moderate heat, and even before they grow red. Being thus melted, they form a blackiſh maſs; and in this form they are uſed by ſurgeons, under the title of *lapis infernalis*, *infernal ſtone*, or *ſilver cauſtic*.

Silver is alſo diſſolved by the vitriolic acid: but then the acid muſt be concentrated, and in quantity double the weight of the ſilver: nor will the ſolution ſucceed without a conſiderable degree of heat.

Spirit of ſalt and *aqua regis*, as well as the other acids, are incapable of diſſolving this metal, at leaſt in the ordinary way.

Though ſilver be not ſoluble in the acid of ſea-ſalt, nor eaſily in the acid of vitriol, as hath juſt been obſerved, it doth not follow, that it hath but a weak affinity with the latter, and none at all with the former: on the contrary, it appears from experiment, that it hath with theſe two acids a much greater affinity than with the acid of nitre: which is ſingular enough, conſidering the facility with which this laſt acid diſſolves it.

The experiment which proves the fact is this. To a ſolution of ſilver in the nitrous acid add the acid either of vitriol or of ſea-ſalt, and the ſilver will inſtantly quit its nitrous ſolvent to join with the ſuperadded acid.

Silver thus united with the vitriolic or the marine acid is leſs ſoluble in water than when combined with the nitrous acid: and for this reaſon it is, that when either of theſe two acids is added to a ſolution of ſilver, the liquor immediately becomes white, and a precipitate is formed, which is no other than the ſilver united with the precipitating acid. If the precipitation be effected by the vitriolic acid, the precipitate will diſappear upon adding a ſufficient quantity of water, becauſe there will then be water enough to diſſolve it. But the caſe is not the ſame when the precipitation is made by the marine acid: for ſilver combined therewith is ſcarce ſoluble in water.

This precipitate of ſilver procured by means of the marine acid is very eaſily fuſed, and when fuſed changes to a ſubſtance in ſome meaſure tranſparent and flexible; which hath occaſioned it to be called by the name of *luna cornea*. If it be propoſed to decompound this *luna cornea*, that is, to ſeparate the marine acid from the ſilver with which it is united, the *luna cornea* muſt be melted along with fatty and abſorbent matters, with which the acid will unite, and leave the metal exceeding pure.

It muſt be obſerved, that if, inſtead of the marine acid, ſea-ſalt in ſubſtance be added to a ſolution of ſilver in the nitrous acid, a precipitate is alſo produced, which by fuſion appears to be a true *luna cornea*. The reaſon is, that the ſea-ſalt is decompoſed by the nitrous acid, which ſeizes its baſis, as having a greater affinity therewith than its own acid hath; and this acid being conſequently diſengaged and ſet at liberty unites with the ſilver, which, as has been ſhewn, has greater affinity with it than with the nitrous acid. This is an inſtance of decompoſition effected by means of one of thoſe double affinities mentioned in the ſeventh propoſition concerning affinities.

From what hath been already ſaid it is clear, that all theſe combinations of ſilver with acids may be decompounded by abſorbent earths and by fixed alkalis; it being a general law with regard to all metallic ſubſtances.

Silver, when ſeparated by theſe means from the acids in which it was diſſolved, requires nothing but ſimple fuſion to reſtore it to its uſual form; becauſe it does not, any more than gold, loſe its phlogiſton by thoſe ſolutions and precipitations.

Silver unites with ſulphur in fuſion. If this metal be only made red-hot in a crucible, and ſulphur be then added,

ded, it immediately flows; the ſulphur acting as a flux to it. Silver thus united with ſulphur forms a maſs that may be cut, is half malleable, and hath nearly the colour and conſiſtence of lead, If this ſulphurated ſilver be kept a long time in fuſion, and in a great degree of heat, the ſulphur flies off and leaves the ſilver pure. But if the ſulphur be evaporated by a violent heat, it carries off with it part of the ſilver.

Silver unites and mixes perfectly with gold in fuſion. The two metals thus mixed form a compound with properties partaking of both.

Metallurgiſts have hitherto ſought in vain for a perfectly good and eaſy method of ſeparating theſe two metals by the *dry way* only: (This term is uſed to ſignify all operations performed by fuſion:) but they are conveniently enough parted by the *moiſt way*, that is, by acid ſolvents. This method is founded on the above-mentioned properties of gold and ſilver with reſpect to acids. It hath been ſhewn, that *aqua regis* only will diſſolve gold; that ſilver, on the contrary, is not ſoluble by *aqua regis*, and that its proper ſolvent is the acid of nitre: Conſequently, when gold and ſilver are mixed together, if the compound maſs be put into *aqua fortis*, this acid will take up all the ſilver, without diſſolving a particle of the gold, which will therefore remain pure; and by this means the deſired ſeparation is effected. This method, which is commonly made uſe of by goldſmiths and in mints, is called the *parting aſſay*.

It is plain, that if *aqua regis* were employed inſtead of *aqua fortis*, the ſeparation would be equally effected; and that the only difference between this proceſs and the former would conſiſt in this, that now the gold would be diſſolved, and the ſilver remain pure. But the operation by *aqua fortis* is preferable; becauſe *aqua regis* does take up a little ſilver, whereas *aqua fortis* hath not the leaſt effect on gold.

It muſt be obſerved, that when gold and ſilver are mixed together in equal parts, they cannot be parted by the means of *aqua fortis*. To enable the *aqua fortis* to act duly on the ſilver, this metal muſt be, at leaſt, in a triple proportion to the gold. If it be in a leſs proportion, you muſt either employ *aqua regis* to make the ſeparation, or, if you prefer the uſe of *aqua fortis*, melt the metalline maſs, and add as much ſilver as is neceſſary to make up the proportion above-mentioned: And hence this proceſs is called *quartation*.

This effect, which is pretty ſingular, probably ariſes from hence, that when the gold exceeds, or even equals the ſilver in quantity, the parts of both being intimately united, the former are capable of coating over the latter, and covering them ſo as to defend them from the action of the *aqua fortis*; which is not the caſe when there is thrice as much ſilver as gold.

There is one thing more to be taken notice of with regard to this proceſs; which is, that perfectly pure *aqua fortis* is rarely to be met with, for two reaſons: Firſt, it is difficult in making it wholly to prevent the riſing of the medium employed to diſengage the nitrous acid; that is, a little of the vitriolic acid will mix with the vapours of the *aqua fortis*: Secondly, unleſs the ſaltpetre be very well purified, it will always hold ſome ſmall portion of ſea-ſalt, the acid of which, we know, is very readily ſet looſe by the vitriolic acid, and conſequently riſes together with the vapours of the *aqua fortis*. It is eaſy to ſee, that *aqua fortis*, mixed either with the one or the other, is not proper for the parting proceſs; becauſe, as has juſt been ſaid, the vitriolic and the marine acid equally precipitate ſilver diſſolved in the nitrous acid; by which means, when they are united with that acid, they weaken its action upon the ſilver, and hinder the diſſolution. Add, that *aqua fortis* adulterated with a mixture of ſpirit of ſalt becomes an *aqua regis*, and conſequently is rendered capable of diſſolving gold, in proportion as its action upon ſilver is diminiſhed.

In order to remedy this inconvenience, and free *aqua fortis* from the vitriolic or marine acid with which it is tainted, ſilver muſt be diſſolved therein: By degrees, as the metal diſſolves, thoſe heterogeneous acids lay hold of it, and precipitate with it in the form of a white powder, as we obſerved before. This precipitate being wholly fallen, the liquor grows clear; after which, if it be found capable of diſſolving more ſilver, without turning milky, it may be depended on as a perfectly pure *aqua fortis*. Then filtre it, diſſolve more ſilver in it, as long as it will take up any, and you will have a ſolution of ſilver in a very pure *aqua fortis*. By means of this ſolution may other *aqua fortis* be purified: For, pour a few drops thereof into a very impure *aqua fortis*, and immediately the vitriolic or marine acid, with which that *aqua fortis* is contaminated, will join the ſilver and fall therewith to the bottom. When the ſolution of ſilver prepared as above does not in the leaſt affect the tranſparency of the *aqua fortis*, it is then very pure, and fit for the purpoſes of quartation.

This operation of purifying *aqua fortis* by a ſolution of ſilver is called the *precipitation of aqua fortis;* and *aqua fortis* thus purified is called *precipitated aqua fortis*.

When ſilver is diſſolved in *aqua fortis* it may be ſeparated therefrom, as has been ſhewn, by abſorbent earths and fixed alkalis.

Of Copper.

Of all the imperfect metals, copper comes the neareſt to gold and ſilver. Its natural colour is a deep-red yellow. It reſiſts a very violent degree of fire for a conſiderable time; but loſing its phlogiſton at laſt, it changes its metalline form for that of a calx, or a pure reddiſh earth. This calx is hardly, if at all, reducible to glaſs, without the addition of ſomething to promote its fuſion; all that the fierceſt heat can do being only to render it ſoft. Copper, even while it retains its metalline form, and is very pure, requires a conſiderable degree of fire to melt it, and does not begin to flow till long after it is red-hot. When in fuſion, it communicates a greeniſh colour to the flame of the coals.

This metal is inferior to ſilver in point of gravity; nor is its ductility ſo great, though it be pretty conſiderable: But, on the other hand, it exceeds that metal in hardneſs. It unites readily with gold and ſilver; nor does it greatly leſſen their beauty when added to them in a ſmall quantity: Nay, it even procures them ſome advantages;

vantages; ſuch as making them harder, and leſs ſubject to loſe their ductility. This may probably ariſe from hence, that the ductility of copper has the peculiarity of reſiſting moſt of thoſe cauſes which rob the perfect metals of theirs.

The property which other metalline ſubſtances have in common with copper, of loſing the phlogiſton by calcining and then vitrifying, furniſhes us with a method of ſeparating them from gold and ſilver, when they are combined therewith. Nothing more is required than to expoſe the maſs, compounded of the perfect metals and other metalline ſubſtances, to a degree of heat ſufficient to calcine whatever is not either gold or ſilver. It is evident that by this means theſe two metals will be obtained as pure as is poſſible; for, as hath already been ſaid, no metalline calx or glaſs is capable of uniting with metals poſſeſſed of their phlogiſton. On this principle is formed the whole buſineſs of refining gold and ſilver.

When the perfect metals have no other alloy but copper, as this metal is not to be calcined or vitrified without great difficulty, which is increaſed by its union with the unvitrifiable metals, it is eaſy to ſee that it is almoſt impoſſible to ſeparate them without adding ſomething to facilitate the vitrification of the copper. Such metals as have the property of turning eaſily to glaſs are very fit for this purpoſe; and it is neceſſary to add a certain quantity thereof, when gold or ſilver is to be purified from the alloy of copper. We ſhall have occaſion to be more particular on this ſubject when we come to treat of lead.

Copper is ſoluble in all the acids, to which it communicates a green colour, and ſometimes a blue. Even the neutral ſalts, and water itſelf, act upon this metal. With regard to water indeed, as the procuring it abſolutely pure and free from any ſaline mixture is next to an impoſſibility, it remains a queſtion, whether the effect it produces on copper be not owing to certain ſaline particles contained in it. It is this great facility of being diſſolved that renders copper ſo ſubject to ruſt; which is nothing elſe but ſome parts of its ſurface corroded by ſaline particles contained in the ſurrounding air and water.

The ruſt of copper is always green or blue, or of a colour between theſe two. Internally uſed it is very noxious, being a real poiſon, as are all the ſolutions of this metal made by any acid whatever. The blue colour, which copper conſtantly aſſumes, when corroded by any ſaline ſubſtance, is a ſure ſign by which it may be diſcovered where-ever it exiſts, even in a very ſmall quantity.

Copper diſſolved in the vitriolic acid forms a kind of metalline ſalt, which ſhoots into rhomboidal cryſtals of a moſt beautiful blue colour. Theſe cryſtals are called *blue vitriol*, or *vitriol of copper*. They are ſometimes found ready formed in the bowels of the earth; and may be artificially made by diſſolving copper in the vitriolic acid; but the ſolution will not ſucceed unleſs the acid be well dephlegmated. The taſte of this vitriol is ſaltiſh and aſtringent. It retains a conſiderable quantity of water in cryſtallizing, on which account it is eaſily rendered fluid by fire.

It muſt be obſerved, that when it is expoſed to a certain degree of heat in order to free it of its humidity, a great part of its acid flies off at the ſame time: And hence it is that, after calcination, there remains only a kind of earth, or metalline calx, of a red colour, which contains but very little acid. This earth cannot be brought to flow but with the greateſt difficulty.

A ſolution of copper in the nitrous acid forms a ſalt which does not cryſtallize, but, when dried, powerfully attracts the moiſture of the air. The ſame thing happens when it is diſſolved in the ſpirit of ſalt, or in *aqua regis*.

If the copper, thus diſſolved by any of theſe acids, be precipitated by an earth or an alkali, it retains nearly the colour it had in the ſolution: But theſe precipitates are ſcarce any thing more than the earth of copper, or copper deprived of moſt of its phlogiſton; ſo that if they were expoſed to a violent fire, without any additament, a great part of them would be converted into an earth that could never be reduced to a metalline form. Therefore, when we intend to reduce theſe precipitates to copper, it is neceſſary to add a certain quantity of a ſubſtance capable of reſtoring to them the phlogiſton they have loſt.

The ſubſtance which hath been found fitteſt for ſuch reductions is charcoal duſt; becauſe charcoal is nothing but a phlogiſton cloſely combined with an earth, which renders it exceedingly fixed, and capable of reſiſting a violent force of fire. But as charcoal will not melt, and conſequently is capable of preventing rather than forwarding the flux of a metalline calx or glaſs, which nevertheleſs is eſſentially neceſſary to complete the reduction, it hath been contrived to mix it, or any other ſubſtance containing the phlogiſton, with ſuch fixed alkalis as eaſily flow, and are fit to promote the flux of other bodies. Theſe mixtures are called *reducing fluxes*; becauſe the general name of fluxes is given to all ſalts, or mixtures of ſalts, which facilitate fuſion.

If ſulphur be applied to copper made perfectly red-hot, the metal immediately runs; and theſe two ſubſtances uniting, form a new compound much more fuſible than pure copper.

This compound is deſtroyed by the ſole force of fire, for two reaſons: The firſt is, that, ſulphur being volatile, the fire is capable of ſubliming a great part of it, eſpecially when it is in a great proportion to the copper with which it is joined; the ſecond is, that the portion of ſulphur which remains, being more intimately united with the copper, though it be rendered leſs combuſtible by that union, is nevertheleſs burnt and conſumed in time. Copper being combined with ſulphur, and together with it expoſed to the force of fire, is found to be partly changed into a blue vitriol; becauſe the vitriolic acid, being diſengaged by burning the ſulphur, is by that means qualified to diſolve the copper. The affinity of copper with ſulphur is geater than that of ſilver.

This metal, as well as the other imperfect metals and the ſemi-metals, being mingled with nitre and expoſed to the fire, is decompoſed and calcined much ſooner than by itſelf; becauſe the phlogiſton which it contains occaſions the deflagration of the nitre, and conſequently the two ſubſtances mutually decompoſe each other. There are certain metalline ſubſtances whoſe phlogiſton is ſo abundant,

dant, and fo weakly connected with their earth, that, when they are thus treated with nitre, there arifes immediately a detonation, accompanied with flame, and as violent as if fulphur or charcoal-duft had been employed; fo that in a moment the metalline fubftance lofes its phlogifton, and is calcined. The nitre, after thefe detonations, always affumes an alkaline character.

Of Iron.

Iron is lighter and lefs ductile than copper; but it is much harder, and of more difficult fufion.

It is the only body that has the property of being attracted by the magnet, which therefore ferves to difcover it where-ever it is. But it muft be obferved, that it hath this property only when in its metalline ftate, and lofes it when converted to an earth or calx. Hence very few iron-ores are attracted by the loadftone; becaufe, for the moft part, they are only forts of earths, which require a phlogifton to be added before they can be brought to the form of true iron.

When iron hath undergone no other preparation but the fufion which is neceffary to fmelt it from its ore, it is ufually quite brittle, and flies to pieces under the hammer: Which arifes in fome meafure from its containing a certain portion of unmetallic earth interpofed between its parts. This we call *pig-iron.*

By melting this a fecond time it is rendered purer, and more free from heterogeneous matters: But ftill, as its proper parts are probably not brought fufficiently near, or clofely enough united, till the iron hath undergone fome further preparation befides that of fufion, it feldom hath any degree of malleability.

The way to give it this property is to make it juft red-hot, and then hammer it for fome time in all directions; to the end that its parts may be properly united, incorporated, and welded together, and that the heterogeneous matters which keep them afunder may be feparated. Iron made by this means as malleable as poffible, we call *bar-iron*, or *forged iron.*

Bar-iron is ftill harder to fufe than pig-iron: To make it flow requires the utmoft force of fire.

Iron has the property of imbibing a greater quantity of phlogifton than is neceffary to give it the metalline form. It may be made to take in this fuperabundant phlogifton two ways: The firft is by fufing it again with matters that contain the phlogifton; the fecond is, by encompaffing it with a quantity of fuch matters, charcoal-duft, for inftance, and then expofing it fo encompaffed, for a certain time, to a degree of fire barely fufficient to keep it red-hot. This fecond method, whereby one fubftance is incorporated with another by means of fire, but without fufing either of them, is in general called *cementation.*

Iron thus impregnated with an additional quantity of phlogifton is called *fteel.* The hardnefs of fteel may be confiderably augmented by *tempering* it; that is, by making it red-hot, and fuddenly quenching it in fome cold liquor. The hotter the metal, and the colder the liquor in which it is quenched, the harder will the fteel be. By this means tools are made, fuch as files and fheers, capable of cutting and dividing the hardeft bodies, as glafs, pebbles, and iron itfelf. The colour of fteel is darker than that of iron, and the facets which appear on breaking it are fmaller. It is alfo lefs ductile and more brittle, efpecially when tempered.

As iron may be impregnated with an additional quantity of phlogifton, and thereby converted into fteel, fo may fteel be again deprived of that fuperabundant phlogifton, and brought back to the condition of iron. This is effected by cementing it with poor earths, fuch as calcined bones and chalk. By the fame operation fteel may be *untempered*: nay, it will lofe the hardnefs it had acquired by tempering, if it be but made red-hot, and left to cool gradually. As iron and fteel differ only in the refpects we have here taken notice of, their properties being in all other refpects the fame, what follows is equally applicable to both.

Iron being expofed to the action of fire for fome time, efpecially when divided into fmall particles, fuch as filings, is calcined, and lofes its phlogifton. By this means it turns to a kind of reddifh yellow earth, which on account of its colour is called *crocus Martis*, or *faffron of Mars.*

This calx of iron has the fingular property of flowing in the fire with fomewhat lefs difficulty than iron itfelf; whereas every other metalline calx flows with lefs eafe than the metal that produced it. It has moreover the remarkable property of uniting with the phlogifton, and of being reduced to iron without fufion; requiring for that purpofe only to be made red-hod.

Iron may be incorporated with filver, and even with gold, by means of certain operations. Under the article of lead, we fhall fee how it may be feparated from thefe metals.

The acids produce on it much the fame effects as on copper: every one of them acts upon it. Certain neutral falts, alkalis, and even water itfelf, are capable of diffolving it; and hence it is alfo very fubject to ruft.

The vitriolic acid diffolves it with the greateft eafe: but the circumftances which attend the diffolution thereof are different from thofe with which the fame acid diffolves copper. For, 1. Whereas the vitriolic acid muft be concentrated to diffolve copper, it muft on the contrary be diluted with water to diffolve iron, which it will not touch when well dephlegmated. 2. The vapours which rife in this diffolution are inflammable; fo that if it be made in a fmall-necked bottle, and the flame of a candle be applied to the mouth thereof, the vapours in the bottle take fire with fuch rapidity as to produce a confiderable explofion.

This folution is of a beautiful green colour; and from this union of the vitriolic acid with iron, there refults a neutral metalline falt, which has the property of fhooting into cryftals of a rhomboidal figure, and a green colour. Thefe cryftals are called *green vitriol*, and *vitriol of Mars.*

Green vitriol hath a faltifh and aftringent tafte. As it retains a great deal of water in cryftallizing it quickly flows by the action of fire: but this fluidity is owing to its water only, and is not a real fufion; for as foon as its moifture is evaporated, it refumes a folid form Its green tranfparent colour is now changed into an opaque white:

white: and, if the calcination be continued, its acid alſo exhales, and is diſſipated in vapours; and as it loſes that, it turns gradually to a yellow colour, which comes ſo much the nearer to a red the longer the calcination is continued, or the higher the force of the fire is raiſed; which being driven to the utmoſt, what remains is of a very deep red. This remainder is nothing but the body of the iron, which, having loſt its phlogiſton, is now no more than an earth, nearly of the ſame nature with that which is left after calcining the metal itſelf.

Green vitriol diſſolved in water ſpontaneouſly lets fall a yellowiſh earthy ſediment. If this ſolution be defecated by filtration, it ſtill continues to depoſite ſome of the ſame ſubſtance, till the vitriol be wholly decompoſed. This ſediment is nothing but the earth of iron, which is then called *ochre*.

The nitrous acid diſſolves iron with great eaſe. This ſolution is of a yellow colour, inclining more or leſs to a ruſſet, or dark-brown, as it is more or leſs ſaturated with iron. Iron diſſolved by this acid alſo falls ſpontaneouſly into a kind of calx, which is incapable of being diſſolved a ſecond time; for the nitrous acid will not act upon iron that has loſt its phlogiſton. This ſolution does not cryſtallize, and if evaporated to dryneſs attracts the moiſture of the air.

Spirit of ſalt likewiſe diſſoves iron, and this ſolution is green. The vapours which riſe during the diſſolution are inflammable, like thoſe which aſcend when this metal is attacked by the vitriolic acid. *Aqua regis* makes a ſolution of iron, which is of a yellow colour.

Iron hath a greater affinity than either ſilver or copper with the nitrous and vitriolic acids: ſo that if iron be preſented to a ſolution of either, in one of theſe two acids, the diſſolved metal will be precipitated; becauſe the acid quits it for the iron, with which it has a greater affinity.

On this occaſion it muſt be obſerved, that if a ſolution of copper in the vitriolic acid be precipitated by means of iron, the precipitate has the form and ſplendour of a metal, and does not require the addition of a phlogiſton to reduce it to true copper; which is not the caſe, when the precipitation is effected by earths or alkaline ſalts.

The colour of this metalline precipitate hath deceived ſeveral perſons, who being unacquainted with ſuch phenomena, and with the nature of blue vitriol, imagined that iron was tranſmuted into copper, when they ſaw a bit of iron, laid in a ſolution of that vitriol, become, in form and external appearance, exactly like copper: whereas the ſurface only of the iron was cruſted over with the particles of copper contained in the vitriol, which had gradually fallen upon, and adhered to the iron, as they were precipitated out of the ſolution.

Among the ſolvents of iron we mentioned fixed alkalis; and that they have ſuch a power, is proved by the following phenomenon. If a large proportion of alkaline ſalts be ſuddenly mixed with a ſolution of iron in an acid, no precipitation enſues, and the liquor remains clear and pellucid; or if at firſt it look a little turbid, that appearance laſts but a moment, and the liquor preſently recovers its tranſparency. The reaſon is, that quantity of alkali is more than ſufficient to ſaturate all the acid of the ſolution; and the ſuperabundant portion thereof, meeting with the iron already finely divided by the acid, diſſolves it with eaſe as faſt as it falls, and ſo prevents its mudding in liquor. To evince that this is ſo in fact, let the alkali be applied in a quantity that is not ſufficient, or but qarely ſufficient, to ſaturate the acid, and the iron will then precipitate like any other metal.

Water alſo acts upon iron; and therefore iron expoſed to moiſture grows ruſty. If iron-filings be expoſed to the dew, they turn wholly to a ruſt, which is called *crocus Martis aperiens*.

Iron expoſed to the fire, together with nitre, makes it detonate pretty briſkly, ſets it in a flame, and decompoſes it with rapidity.

This metal hath a greater affinity than any other metalline ſubſtance with ſulphur; on which account, it is ſucceſsfully uſed to precipitate, and ſeparate all metalline ſubſtances combined with ſulphur.

Sulphur uniting with iron communicates to it ſuch a degree of fuſibility, that if a maſs of this metal, heated red-hot, be rubbed with a bit of ſulphur, it inceſſantly runs into as perfect a fuſion as a metal expoſed to the focus of a large burning-glaſs.

Of TIN.

TIN is the lighteſt of all metals. Though it yields eaſily to the impreſſion of hard bodies, it has but little ductility. Being bent backwards and forwards it makes a ſmall crackling noiſe. It flows with a very moderate degree of fire, and long before it comes to be red-hot. When it is in fuſion, its ſurface ſoon grows duſky, and there forms upon it a thin dark-coloured duſty pellicle, which is no other than a part of the tin that has loſt its phlogiſton, or a calx of tin. The metal thus calcined eaſily recovers its metalline form, on the addition of a phlogiſton. If the calx of tin be urged by a ſtrong fire it grows white, but the greateſt violence of heat will not fuſe it; which makes ſome chemiſts conſider it as a calcinable or abſorbent earth, rather than a vitrifiable one. Yet it turns to glaſs in ſome ſort, when mixed with any other ſubſtance that vitrifies eaſily. However, it always produces an imperfect glaſs only, which is not at all tranſparent, but of an opaque white. The calx of tin thus vitrified is called *enamel*. Enamels are made of ſeveral colours by the addition of this or that metalline calx.

Tin unites eaſily with all the metals; but it deſtroys the ductility and malleability of every one of them, lead excepted. Nay, it poſſeſſes this property of making metals brittle, in ſuch an eminent degree, that the very vapour of it, when in fuſion, is capable of producing this effect. Moreover, which is very ſingular, the moſt ductile metals, even gold and ſilver, are thoſe on which it works this change with the moſt eaſe, and in the greateſt degree. It has alſo the property of making ſilver, mixed with it, flow over a very ſmall fire.

It adheres to, and in ſome meaſure incorporates with, the ſurface of copper and of iron; whence aroſe the practice of coating over thoſe metals with tin. Tin-plates are no other than thin plates of iron tinned over.

If to twenty parts of tin one part of copper be added, this

this alloy renders it much more ſolid, and the mixed maſs continues tolerably ductile.

If, on the contrary, to one part of tin ten parts of copper be added, together with a little zinc, a ſemi-metal to be conſidered hereafter, from this combination there reſults a metalline compound, which is hard, brittle, and very ſonorous; ſo that it is uſed for caſting bells: This compoſition is called *bronze* and *bell-metal*.

Tin hath an affinity with the vitriolic, nitrous, and marine acids. All of them attack and corrode it; yet none of them is able to diſſolve it without great difficulty: So that if a clear ſolution thereof be deſired, particular methods muſt be employed for that purpoſe; for the acids do but in a manner calcine it, and convert it to a kind of white calx or precipitate. The ſolvent which has the greateſt power over it is *aqua regis*, which has even a greater affinity therewith than with gold itſelf; whence it follows, that gold diſſolved in *aqua regis* may be precipitated by means of tin; but then the *aqua regis* muſt be weakened. Gold thus precipitated by tin is of a moſt beautiful colour, and is uſed for a red in enamelling and painting on porcelain, as alſo to give a red colour to artificial gems. If the *aqua regis* be not lowered, the precipitate will not have the purple colour.

Tin hath the property of giving a great luſtre to all red colours in general; on which account it is uſed by the dyers for ſtriking a beautiful ſcarlet, and tin-veſſels are employed in making fine ſyrup of violets. Water does not act upon this metal, as it does upon iron and copper; for which reaſon it is not ſubject to ruſt: neverthelefs, when it is expoſed to the air, its ſurface ſoon loſes its poliſh and ſplendor.

Tin mixed with nitre, and expoſed to the fire, deflagrates with it, makes it detonate, and is immediately converted to a *refractory calx*; for ſo all ſubſtances are called which are incapable of fuſion.

Tin readily unites with ſulphur, and with it becomes a brittle and friable maſs.

Of LEAD.

NEXT to gold and mercury, lead is the heavieſt of all metalline ſubſtances, but in hardneſs is exceeded by every one of them. Of all metals alſo it melts the eaſieſt, except tin. While it is in fuſion there gathers inceſſantly on its ſurface, as on that of tin, a blackiſh, duſty pellicle, which is nothing but a calx of lead.

This calx further calcined by a moderate fire, the flame being reverberated on it, ſoon grows white. If the calcination be continued it becomes yellow, and at laſt of a beautiful red. In this ſtate it is called *minium*, and is uſed as a pigment. *Minium* is not eaſily made, and the operation ſucceeds well in large manufactures only.

To convert lead into *litharge*, which is the metal in a manner half vitrified, you need only keep it melted by a pretty ſtrong fire; for then, as its ſurface gradually calcines, it tends more and more to fuſion and vitrification.

All theſe preparations of lead are greatly diſpoſed to perfect fuſion and vitrification, and for that purpoſe require but a moderate degree of fire; the calx or earth of lead being of all metalline earths that which vitrifies the moſt eaſily.

Lead hath not only the property of turning into glaſs with the greateſt facility, but it hath alſo that of promoting greatly the vitrification of all the other imperfect metals; and, when it is actually vitrified, procures the ready fuſion of all earths and ſtones in general, even thoſe which are refractory, that is, which could not be fuſed without its help.

Glaſs of lead, beſides its great fuſibility, hath alſo the ſingular property of being ſo ſubtile and active as to corrode and penetrate the crucibles in which it is melted, unleſs they be of an earth that is exceeding hard, compact, and withal very refractory: for glaſs of lead being one of the moſt powerful fluxes that we know, if the earth of the crucible in which it is melted be in the ſmalleſt degree fuſible, it will be immediately vitrified; eſpecially if there be any metallic matter in its compoſition.

The great activity of glaſs of lead may be weakened by joining it with other vitrifiable matters; but unleſs theſe be added in a very great proportion, it will ſtill remain powerful enough to penetrate common earths, and carry off the matters combined with it.

On theſe properties of lead, and of the glaſs of lead, depends the whole buſineſs of refining gold and ſilver. It hath been ſhewn, that as theſe two metals are indeſtructible by fire, and the only ones which have that advantage, they may be ſeparated from the imperfect metals, when mixed therewith, by expoſing the compound to a degree of fire ſufficiently ſtrong to vitrify the latter; which when once converted into glaſs can no longer remain united with any metal that has its metalline form. But it is very difficult to procure this vitrification of the imperfect metals, when united with gold and ſilver; nay, it is in a manner impoſſible to vitrify them entirely, for two reaſons: firſt, becauſe moſt of them are naturally very difficult to vitrify: ſecondly, becauſe the union they have contracted with the perfect metals defends them, in a manner, from the action of the fire, and that ſo much the more effectually as the proportion of the perfect metals is greater; which being indeſtructible, and in ſome ſort coating over thoſe with which they are alloyed, ſerve them as a preſervative and impenetrable ſhield againſt the utmoſt violence of fire.

It is therefore clear, that a great deal of labour may be ſaved, and that gold and ſilver may be refined to a much greater degree of purity than can otherwiſe be obtained, if to a mixture of theſe metals with copper, for inſtance, or any other imperfect metal, be added a certain quantity of lead. For the lead, by its known property, will infallibly produce the deſired vitrification; and as it likewiſe increaſes the proportion of the imperfect metals, and ſo leſſens that of the perfect metals, in the maſs, it evidently deprives the former of a part of their guard, and ſo effects a more complete vitrification. As the glaſs of lead hath the property of running through the crucible, and carrying with it the matters which it has vitrified, it follows, that when the vitrification of the imperfect metals is effected by its means, all thoſe vitrified matters together penetrate the veſſel containing the fuſed metalline maſs, diſappear, and leave only the gold and ſilver perfectly

perfectly pure, and freed, as far as is poſſible, from all admixture of heterogeneous parts.

The better to promote the ſeparation of ſuch parts, it is uſual to employ in this proceſs a particular ſort of ſmall crucibles, made of the aſhes of calcined bones, which are exceedingly porous and eaſily pervaded. They are called *cupels*, on account of their figure, which is that of a wide-mouthed cup: and from hence the operation takes its name; for when we refine gold and ſilver in this manner, we are ſaid to *cupel* thoſe metals. It is eaſy to perceive, that the more lead is added, the more accurately will the gold and ſilver be refined; and that ſo much the more lead ought to be added as the perfect metals are alloyed with a greater proportion of the imperfect. This is the moſt ſevere trial to which a perfect metal can be put, and conſequently any metal that ſtands it may be fairly conſidered as ſuch.

In order to denote the fineneſs of gold, it is ſuppoſed to be divided into twenty-four parts called *carats*; and gold, which is quite pure and free from all alloy, is ſaid to be twenty-four carats fine; that which contains $\frac{1}{24}$ part of alloy is called gold of twenty-three carats; that which contains $\frac{2}{24}$ of alloy is but twenty-two carats; and ſo on. Silver again is ſuppoſed to be divided into twelve parts only, which are called *penny-weights*; ſo that when abſolutely pure it is ſaid to be twelve penny-weights fine; when it contains $\frac{1}{12}$ of alloy, it is then called eleven penny-weights fine; when it contains $\frac{2}{12}$ of alloy, it is called ten penny-weights fine; and ſo on.

In treating of copper, we promiſed to ſhew under the article of lead how to ſeparate it from iron. The proceſs is founded on that property of lead which renders it incapable of mixing and uniting with iron, though it readily diſſolves all other metalline ſubſtances. Therefore if you have a maſs compounded of copper and iron, it muſt be fuſed with a certain quantity of lead, and then the copper, having a greater affinity with lead than with iron, will deſert the latter and join the former, which being incapable of any union with iron, as was ſaid, will wholly exclude it from the new compound. The next point is to ſeparate the lead from the copper; which is done by expoſing the maſs compounded of theſe two metals to a degree of fire ſtrong enough to deprive the lead of its metalline form, but too weak to have the ſame effect on the copper: and this may be done, ſince of all the imperfect metals lead is, next to tin, the eaſieſt to be calcined, and copper, on the contrary, reſiſts the greateſt force of fire longeſt, without loſing its metalline form. Now what we gain by this exchange, *viz.* by ſeparating copper from iron, and uniting it with lead, conſiſts in this, that as lead is calcined with leſs fire than iron, the copper is leſs expoſed to be deſtroyed: for it muſt be obſerved, that, however moderate the fire be, it is hardly poſſible to prevent a certain quantity thereof from being calcined in the operation.

Lead melted with a third part of tin forms a compound, which being expoſed to a fire capable of making it thoroughly red hot, ſwells, puffs up, ſeems in ſome ſort to take fire, and is preſently calcined. Theſe two metals mixed together are much ſooner calcined than either of them ſeparately.

Both lead and tin are in ſome meaſure affected by water, and by a moiſt air; but they are both much leſs ſubject than iron or copper to be corroded by theſe ſolvents, and of courſe are much leſs liable to ruſt.

The vitriolic acid acts upon and diſſolves lead much in the ſame manner as it doth ſilver.

The nitrous acid diſſolves this metal with much eaſe, and in great quantities; and from this ſolution a ſmall portion of mercury may be obtained.

When this ſolution of lead is diluted with a good deal of water, the lead precipitates in the form of a white powder; which happens becauſe the acid is rendered too weak to keep the lead diſſolved.

If this ſolution of lead be evaporated to a certain degree, it ſhoots into cryſtals formed like regular pyramids with ſquare baſes. Theſe cryſtals are of a yellowiſh colour, and of a ſaccharine taſte: they do not eaſily diſſolve in water. This nitrous metalline ſalt has the ſingular property of detonating in a crucible, without any additament, or the contact of any other inflammable ſubſtance. This property it derives from the great quantity of phlogiſton contained in, and but looſely connected with the lead, which is one of its principles.

If ſpirit of ſalt, or even ſea-ſalt in ſubſtance, be added to a ſolution of lead in the nitrous acid, a white precipitate immediately falls; which is no other than the lead united with the marine acid. This precipitate is extremely like the precipitate of ſilver made in the ſame manner; and that being called *luna cornea*, hath occaſioned this to be named *plumbum corneum*. Like the *luna cornea*, it is very fuſible, and, being melted, hardens like it into a kind of horny ſubſtance: it is volatile, and may be reduced by means of inflammable matters combined with alkalis. But it differs from the *luna cornea* in this chiefly, that it diſſolves eaſily in water; whereas the *luna cornea*, on the contrary, diſſolves therein with great difficulty, and in a very ſmall quantity.

As this precipitation of lead from its ſolution in ſpirit of nitre is procured by the marine acid, lead is thereby proved to have a greater affinity with the latter acid than with the former. Yet, if you attempt to diſſolve lead directly by the acid of ſea-ſalt, the ſolution is not ſo eaſily effected as by the ſpirit of nitre, and it is always imperfect; for it wants one of the conditions eſſential to every ſolution in a liquor, namely tranſparency.

If lead be boiled for a long time in a lixivium of fixed alkali, part of it will be diſſolved.

Sulphur renders this metal refractory and ſcarce fuſible; and the maſs they form when united together is friable. Hence it appears that ſulphur acts upon lead much in the ſame manner as upon tin; that is, it renders both theſe metals leſs fuſible, which are naturally the moſt fuſible of any, while it exceedingly facilitates the fuſion of ſilver, copper, and iron, metals which of themſelves flow with the greateſt difficulty.

Of QUICK-SILVER.

WE treat of quick-ſilver in a chapter apart, becauſe this metallic ſubſtance cannot be claſſed with the metals properly ſo called, and yet has ſome properties which will

will not allow us to confound it with the semi metals. The reason why quick-silver, by the chemists commonly called mercury, is not reputed a metal, is, that it wants one of the essential properties thereof, *viz.* malleability. When it is pure and unadulterated with any mixture, it is always fluid, and of course unmalleable. But as, on the other hand, it eminently possesses the opacity, the splendor, and above all the gravity of a metal, being, next to gold, the heaviest of all bodies, it may be considered as a true metal, differing from the rest no otherwise than by being constantly in fusion; which we may suppose arises from its aptness to flow with such a small degree of heat, that be there ever so little warmth on earth, there is still more than enough to keep mercury in fusion; which would become solid and malleable if it were possible to apply to it a degree of cold considerable enough for that purpose. These properties will not allow us to confound it with the semi-metals. Add, that we are not yet assured by any undoubted experiment that it can be wholly deprived of its phlogiston, as the imperfect metals may. Indeed we cannot apply the force of fire to it as could be wished: for it is so volatile, that it flies off and exhales in vapours with a much less degree of fire than is necessary to make it red-hot. The vapours of mercury thus raised by the action of fire, being collected and united in a certain quantity, appear to be no other than true mercury retaining every one of its properties; and no experiment hath ever been able to shew the least change thus produced in its nature.

If mercury be exposed to the greatest heat that it can bear without sublimation, and continued in it for several months, or even a whole year together, it turns to a red powder, which the chemists call *mercurius præcipitatus per se*. But to succeed in this operation, it is absolutely necessary that the heat be such as is above specified; for this metallic substance may remain exposed to a weaker heat for a considerable number of years, without undergoing any sensible alteration.

Some chemists fancied that by this operation they had fixed mercury, and changed its nature; but without any reason; for if the mercury thus seemingly transmuted be exposed to a somewhat stronger degree of fire, it sublimes and exhales in vapours as usual; and those vapours collected are nothing else but running mercury, which has recovered all its properties without the help of any additament.

Mercury has the property of dissolving all the metals, iron only excepted. But it is a condition absolutely necessary to the success of such dissolution, that the metalline substances be possessed of their phlogiston; for if they be calcined, mercury cannot touch them: and hence it follows, that mercury doth not unite with substances that are purely earthy. Such a combination of a metal with mercury is called an *amalgam*. Trituration alone is sufficient to effect it; however, a proper degree of heat also is of use.

Mercury amalgamated with a metal gives it a consistence more or less soft, and even fluid, according to the greater or smaller proportion of mercury employed. All amalgams are softened by heat, and hardened by cold.

Mercury is very volatile; vastly more so than the most unfixed metals: moreover, the union it contracts with any metal is not sufficiently intimate to entitle the new compound resulting from that union to all the properties of the two substances united; at least with regard to their degree of fixity and volatility. From all which it follows, that the best and surest method of separating it from metals dissolved by it, is to expose the amalgam to a degree of heat sufficient to make all the quick-silver rise and evaporate; after which the metal remains in the form of a powder, and being fused recovers its malleability. If it be thought proper to save the quick-silver, the operation must be performed in close vessels, which will confine and collect the mercurial vapours. This operation is most frequently employed to separate gold and silver from the several sorts of earths and sands with which they are mixed in the ore; because these two metals, gold especially, are of sufficient value to compensate the loss of mercury, which is inevitable in this process: besides, as they very readily amalgamate with it, this way of separating them from every thing unmetallic is very commodious.

Mercury is dissolved by acids; but with circumstances peculiar to each particular acid.

The vitriolic acid concentrated and made boiling hot seizes on it, and presently reduces it to a kind of white powder, which turns yellow by the affusion of water, but does not dissolve in it: it is called *turbith mineral*. However, the vitriolic acid on this occasion unites with a great part of the mercury in such a manner that the compound is soluble in water. For if to the water which was used to wash the turbith a fixed alkali be added, there falls instantly a russet-coloured precipitate, which is no other than mercury separated from the vitriolic acid by the intervention of the alkali.

This dissolution of mercury by the vitriolic acid is accompanied with a very remarkable phenomenon; which is, that the acid contracts a strong smell of volatile spirit of sulphur: a notable proof that part of the phlogiston of the mercury hath united therewith. And yet, if the mercury be separated by means of a fixed alkali, it does not appear to have suffered any alteration. Turbith mineral is not so volatile as pure mercury.

The nitrous acid dissolves mercury with ease. The solution is limpid and transparent, and as it grows cold shoots into crystals, which are a nitrous mercurial salt.

If this solution be evaporated to driness, the mercury remains impregnated with a little of the acid, under the form of a red powder, which hath obtained the names of *red precipitate*, and *arcanum corallinum*. This precipitate, as well as turbith, is less volatile than pure mercury.

If this solution of mercury be mixed with a solution of copper made likewise in the nitrous acid, and the mixture evaporated to driness, there will remain a green powder called *green precipitate*. These precipitates are caustic and corrosive; and are used as such in surgery.

Though mercury be dissolved more easily and completely by the nitrous acid than by the vitriolic, yet it has a greater affinity with the latter than with the former; for if a vitriolic acid be poured into a solution of mercury in spirit of nitre, the mercury will quit the lat-

ter acid in which it was diſſolved, and join the other which was added. The ſame thing happens when the marine acid is employed inſtead of the vitriolic.

Mercury combined with ſpirit of ſalt forms a ſingular body; a metalline ſalt which ſhoots into long cryſtals, pointed like daggers. This ſalt is volatile, and ſublimes eaſily without decompoſition. It is moreover the moſt violent of all the corroſives hitherto diſcovered by chemiſtry. It is called *corroſive ſublimate*, becauſe it muſt abſolutely be ſublimed to make the combination perfect. There are ſeveral ways of doing this: but the operation will never fail, if the mercury be rarefied into vapours and meet with the marine acid in a ſimilar ſtate.

Corroſive ſublimate is diſſoved by water, but in very ſmall quantities only. It is decompounded by fixed alkalis, which precipitate the mercury in a reddiſh yellow powder, called, on account of its colour, *yellow precipitate*.

If corroſive ſublimate be mixed with tin, and the compound diſtilled, a liquor comes over, which continually emits abundance of denſe fumes, and from the name of its inventor is called the *ſmoking liquor of Libavius*. This liquor is no other than the tin combined with the marine acid of the corroſive ſublimate, which therefore it hath actually decompounded: whence it follows, that this acid hath a greater affinity with tin than with mercury.

The marine acid in corroſive ſublimate is not quite ſaturated with mercury; but is capable of taking up a much greater quantity thereof. For if corroſive ſublimate be mixed with freſh mercury, and ſublimed a ſecond time, another compound will be produced containing much more mercury, and leſs acrimonious; for which reaſon it is named *ſweet ſublimate of mercury, mercurius dulcis, aquila alba*. This compound may be taken internally, and is purgative or emetic according to the doſe adminiſtered. It may be rendered ſtill more gentle by repeated ſublimations, and then it takes the title of *panacæa mercurialis*. No way hath hitherto been found to diſſolve mercury in *aqua regis* without great difficulty, and even then it is but imperfectly diſſolved.

Mercury unites eaſily and intimately with ſulphur. If theſe two ſubſtances be only rubbed together in a gentle heat, or even without any heat, they will contract an union, though but an incomplete one. This combination takes the form of a black powder, which has procured it the name of *Æthiops mineral*.

If a more intimate and perfect union be deſired, this compound muſt be expoſed to a ſtronger heat; and then a red ponderous ſubſtance will be ſublimed, appearing like a maſs of ſhining needles: this is the combination deſired, and is called *cinabar*. In this form chiefly is mercury found in the bowels of the earth. Cinabar finely levigated acquires a much brighter red colour, and is known to painters by the name of *vermilion*.

Cinabar riſes wholly by ſublimation, without ſuffering any decompoſition; becauſe the two ſubſtances of which it conſiſts, *viz.* mercury and ſulphur, are both volatile.

Though mercury unites and combines very well with ſulphur, as hath been ſaid, yet it hath leſs affinity with that mineral than any other metal, gold only excepted: whence it follows, that any of the other metals will decompound cinabar, by uniting with its ſulphur, and ſo ſetting the mercury at liberty to appear in its uſual form. Mercury thus ſeparated from ſulphur, is eſteemed the pureſt, and bears the name of *mercury revivified from cinabar*.

Iron is generally uſed in this operation preferably to the other metals, becauſe among them all it has the greateſt affinity with ſulphur, and is the only one that has none with mercury.

Cinabar may alſo be decompounded by means of fixed alkalis; the affinity of theſe ſalts with ſulphur being generally greater than that of any metalline ſubſtance whatever.

Of the Semi-Metals.

Of Regulus *of* Antimony.

Regulus of antimony is a metallic ſubſtance of a pretty bright white colour. It has the ſplendor, opacity, and gravity of a metal; but it is quite unmalleable, and crumbles to duſt, inſtead of yielding or ſtretching under the hammer; on which account it is claſſed with the ſemi-metals.

It begins to flow as ſoon as it is moderately red; but, like the other ſemi-metals, it cannot ſtand a violent degree of fire; being thereby diſſipated into ſmoke and white vapours, which adhere to ſuch cold bodies as they meet with, and ſo are collected into a kind of *farina* called *flowers of antimony*.

If regulus of antimony, inſtead of being expoſed to a ſtrong fire, be only heated ſo moderately that it ſhall not even melt, it will calcine, loſe its phlogiſton, and take the form of a greyiſh powder deſtitute of all ſplendor: this powder is called *calx of antimony*.

This calx is not volatile like the regulus, but will endure a very violent fire; and being expoſed thereto will flow, and turn to a glaſs of the yellowiſh colour of a hyacinth.

It is to be obſerved, that the more the regulus is deprived of its phlogiſton by continued calcination, the more refractory is the calx obtained from it. The glaſs thereof has alſo ſo much the leſs colour, and comes the nearer to common glaſs.

The calx and the glaſs of antimony will recover their metalline form, like every other calx and glaſs of a metal, if reduced by reſtoring to them their loſt phlogiſton. Yet, if the calcination be carried too far, their reduction will become much more difficult, and a much ſmaller quantity of regulus will be reſuſcitated.

Regulus of antimony is capable of diſſolving the metals; but its affinities with them are various, and differ according to the following order. It affects iron the moſt powerfully, next copper, then tin, lead, and ſilver. It promotes the fuſion of metals, but makes them all brittle and unmalleable.

It will not amalgamate with mercury; and though, by certain proceſſes, particularly the addition of water and continued trituration, a ſort of union between theſe two ſub-

substances may be produced, yet it is but apparent and momentary; for being left to themselves, and undisturbed, they quickly disunite and separate.

The vitriolic acid, assisted by heat, and even by distillation, dissolves regulus of antimony. The nitrous acid likewise attacks it; but the solution can by no art be made clear and limpid; so that the regulus is only calcined, in a manner, by this acid.

The marine acid dissolves it well enough; but then it must be exceedingly concentrated, and applied in a peculiar manner, and especially by distillation. One of the best methods of procuring a perfect union between the acid of sea-salt and regulus of antimony, is to pulverize the latter, mix it with corrosive sublimate, and distil the whole. There rises in the operation a white matter, thick, and scarce fluid, which is no other than the regulus of antimony united and combined with the acid of sea-salt. This compound is extremely corrosive, and is called *butter of antimony*.

It is plain, that the corrosive sublimate is here decompounded; that the mercury is revivified; and that the acid which was combined therewith hath quitted it to join the regulus of antimony, with which its affinity is greater. This butter of antimony, by repeated distillations, acquires a considerable degree of fluidity and limpidness.

If the acid of nitre be mixed with butter of antimony, and the whole distilled, there rises an acid liquor, or a sort of *aqua regis*, which still retains some of the dissolved regulus, and is called *bezoardic spirit of nitre*. After the distillation there remains a white matter, from which fresh spirit of nitre is again abstracted, and which being then washed with water, is called *bezoar mineral*. This bezoar mineral is neither so volatile, nor so caustic, as butter of antimony; because the nitrous acid hath not the property of volatilizing metallic substances, as the marine acid does, and because it remains much more intimately combined with the reguline part.

If butter of antimony be mixed with water, the liquor immediately becomes turbid and milky, and a precipitate falls, which is nothing but the metallic matter partly separated from its acid, which is too much weakened by the addition of water to keep it dissolved. Yet this precipitate still retains a good deal of acid; for which reason it continues to be a violent emetic, and in some degree corrosive. It hath therefore been very improperly called *mercurius vitæ*.

The proper solvent of regulus of antimony is *aqua regis*; by means whereof a clear and limpid solution of this semi-metal may be obtained.

Regulus of antimony mixed with nitre, and projected into a red-hot crucible, sets the nitre in a flame, and makes it detonate. As it produces this effect by means of its phlogiston, it must needs, at the same time, be calcined, and lose its metallic properties, which accordingly happens: and when the nitre is in a triple proportion to the regulus, the latter is so perfectly calcined as to leave only a white powder, which is fused with great difficulty, and then turns to a faintly coloured glass, not very different from common glass, and which is not reducible to a regulus by the addition of inflammable matter; at least it yields but a very small quantity thereof. If less nitre be used, the calx is not so white; the glass it produces is more like a metalline glass, and is more easily reduced. The calx of the regulus thus prepared by nitre is called, on account of the medicinal virtue ascribed to it, *diaphoretic antimony*, or *diaphoretic mineral*.

Nitre always becomes an alkali by deflagration, and in the present case retains part of the calx, which it even renders soluble in water. This calx may be separated from the alkali, if an acid be employed to precipitate it; and then it is called *materia perlata*. This pearly matter is a calx of antimony, so completely deprived of its phlogiston as to be altogether incapable of reduction to a regulus.

Regulus of antimony readily joins and unites with sulphur, forming therewith a compound which has a very faint metallic splendor. This compound appears like a mass of long needles adhering together laterally; and under this form it is usually found in the ore, or at least when only separated by fusion from the stones and earthy matters with which the ore is mixed. It is called *crude antimony*.

Antimony flows with a moderate heat, and becomes even more fluid than other metallic substances. The action of fire dissipates or consumes the sulphur it contains, and its phlogiston also, so as to convert it into a calx and a glass, as it does the regulus.

Aqua regis, which we observed to be the proper solvent of the regulus, being poured on antimony, attacks and dissolves the reguline part, but touches not the sulphur; in consequence whereof it decomposes the antimony, and separates its sulphur from its regulus.

There are several other ways of effecting this decomposition, and obtaining the reguline part of antimony by itself: They consist either in destroying the sulphureous part of the antimony by combustion, or in melting the antimony with some substance which has a greater affinity than its reguline part with sulphur. Most metals are very fit for this latter purpose: For though the regulus has a considerable affinity with sulphur, yet all the metals, except gold and mercury, have a greater.

If therefore iron, copper, lead, silver, or tin, be melted with antimony, the metal employed will unite with the sulphur, and separate it from the regulus.

It must be observed, that, as these metals have some affinity with the regulus of antimony, the regulus will be joined in the operation by some of the metal employed as a precipitant, (so those substances are called which serve as the means of separating two bodies from each other;) and therefore the regulus procured in this manner will not be absolutely pure: On this account care is taken to distinguish each by adding the name of the metal employed in its precipitation; and thence come these titles, *martial regulus of antimony*, or only *martial regulus*, *regulus veneris*; and so of the rest.

Antimony is employed with advantage to separate gold from all other metals with which it may be alloyed. It has been shewn, that all the metals have a greater affinity, than the reguline part of antimony, with sulphur, gold only excepted; which is incapable of contracting any union therewith: And therefore, if a mass compounded of gold and several other metals be melted with anti-

antimony, every thing in that mafs which is not gold will unite with the fulphur of the antimony. This union occafions two feparations, to wit, that of the fulphur of the antimony from its reguline part, and that of the gold from the metals with which it was adulterated; and from the whole two new compounds arife; namely, a combination of the metals with the fulphur, which being lighteft rifes to the furface in fufion; and a metalline mafs formed of the gold and the reguline part of the antimony united together, which being much the heavieft finks to the bottom. There is no difficulty in parting the gold from the regulus of antimony with which it is alloyed: For the metalline mafs need only be expofed to a degree of fire capable of diffipating into vapours all the femi-metal it contains; which being very volatile, the operation is much eafier, and more expeditioufly finifhed, than if the metals with which the gold was debafed were to be vitrified on the cupel; without taking into the account that if filver were one of them, recourfe muft needs be had to the procefs of quartation after that of the cupel.

If equal parts of nitre and antimony be mixed together, and the mixture expofed to the action of fire, a violent detonation enfues; the nitre deflagrating confumes the fulphur of the antimony, and even a part of its phlogifton. After the detonation there remains a greyifh matter which contains fixed nitre, vitriolated tartar, and the reguline part of the antimony in fome meafure deprived of its phlogifton, and half vitrified by the action of the fire, which is confiderably increafed by the deflagration. This matter is called *liver of antimony*.

If inftead of equal parts of nitre and antimony, two parts of the former be ufed to one of the latter, then the reguline part lofes much more of its phlogifton, and remains in the form of a yellowifh powder.

Again, if three parts of nitre be taken to one of antimony, the regulus is thereby entirely robbed of its phlogifton, and converted to a white calx which bears the name of *diaphoretic antimony*, or *diaphoretic mineral*. The pearly matter may be precipitated by pouring an acid on the faline fubftances which here remain after the detonation, in the fame manner as we fhewed above was to be done with regard to the regulus.

In the laft two operations, where the nitre is in a double or triple proportion to the antimony, the reguline part is found after the detonation to be converted into a calx, and not into a half vitrified matter, which we have feen is the effect when equal parts only of nitre and antimony are ufed. The reafon of this difference is, that in thefe two cafes the reguline part, being wholly, or almoft wholly, deprived of its phlogifton, becomes, as was obferved, more difficult to fufe, and confequently cannot begin to vitrify in the fame degree of heat as that which hath not loft fo much of its phlogifton. If, inftead of performing the operation with equal parts of nitre and antimony alone, a portion of fome fubftance which abounds with phlogifton be added, in that cafe the fulphur only of the antimony will be confumed, and the regulus will remain united with its phlogifton, and feparated from its fulphur.

The regulus prepared in this manner is abfolutely pure, becaufe no metalline fubftance being employed, none can mix with it and adulterate it. It is called *regulus of antimony per fe*, or only *regulus of antimony*.

It is true indeed, that in this operation, much of the reguline part unavoidably lofes its phlogifton and is calcined, and confequently a much fmaller quantity of regulus is obtained than when metalline precipitants are employed: But this lofs is eafily repaired, if it be thought proper, by reftoring to the calcined part its loft phlogifton.

Antimony melted with two parts of fixed alkali yields no regulus, but is entirely diffolved by the falt, and forms with it a mafs of a reddifh yellow colour.

The reafon why no precipitate is produced on this occafion is, that the alkali uniting with the fulphur of the antimony forms therewith the combination called *liver of fulphur*, which by its nature is qualified to keep the reguline part diffolved. This mafs, formed by the union of the antimony with the alkali, is foluble in water. If any acid whatever be dropt into this folution, there falls a precipitate of a reddifh yellow colour; becaufe the acid unites with the alkali, and forces it to quit the matters with which it is combined. This precipitate is called *golden fulphur of antimony*.

As in the operation for preparing regulus of antimony *per fe*, fome of the nitre is, by the inflammable matters added thereto, turned to an alkali; this alkali feizes on part of the antimony, and therewith forms a compound like that juft defcribed. Hence it comes, that if the fcoria formed in this procefs be diffolved in water, and an acid dropped into the folution, a true golden fulphur of antimony is thereby feparated.

This union of antimony with an alkali may alfo be brought about by the humid way; that is, by making ufe of an alkali refolved into a liquor, and boiling the mineral in it. The alkaline liquor, in proportion as it acts upon the antimony, gradually becomes reddifh and turbid. If left to fettle and cool, when well faturated therewith, it gradually depofites the antimony it had taken up, which precipitates in the form of a red powder: And this precipitate is the celebrated remedy known by the name of *kermes mineral*. It is plain, that the kermes is nearly the fame thing with the golden fulphur: Yet it differs from it in fome refpects; and efpecially in this, that being taken inwardly it operates much more gently than the golden fulphur, which is a violent emetic. Nitre, fixed by charcoal, and refolved into a liquor, is the only alkali employed in preparing the kermes.

It was fhewn above, that regulus of antimony, mixed and diftilled with corrofive fublimate, decompounds it, difengages the mercury, and joining itfelf to the marine acid forms therewith a new combination, called *butter of antimony*. If the fame operation be performed with crude antimony inftead of its regulus, the fame effects are produced; but then the antimony itfelf is alfo decompofed; that is, the reguline part is feparated from the fulphur, which being fet free unites with the mercury, now alfo at liberty, and thefe two together form a true cinabar, called *cinabar of antimony*.

Of Bismuth.

Bismuth, known alfo by the name *tin-glafs*, is a femi-metal, having almoft the fame appearance as regulus of antimony; yet it has a more dufky caft, inclining fomewhat to red, and even prefents fome changeable ftreaks, efpecially after lying long in the air.

When expofed to the fire it melts long before it is red, and confequently with lefs heat than regulus of antimony, which does not flow, as was fhewn above, till it begin to be red hot. It becomes volatile, like all the other femi-metals, when acted on by a violent fire: Being kept in fufion by a proper degree of heat it lofes its phlogifton with its metallic form, and turns to powder or a calx; and that again is converted into glafs by the continued action of fire. The calx and glafs of bifmuth may be reduced, like any other metallic calx, by reftoring their phlogifton.

Bifmuth mixes with all the metals in fufion, and even facilitates the fufion of fuch as do not otherwife flow readily. It whitens them by its union, and deftroys their malleability.

It amalgamates with mercury, if they be rubbed together with the addition of water: Yet after fome time thefe two metalline fubftances defert each other, and the bifmuth appears again in the form of a powder. Hence it is plain that the union it contracts with mercury is not perfect; and yet it has the fingular property of attenuating lead, and altering it in fuch a manner that it afterwards amalgamates with mercury much more perfectly, fo as even to pafs with it through fhamoy leather without any feparation. The bifmuth employed in making this amalgama afterwards feparates from it fpontaneoufly, as ufual; but the lead ftill continues united with the mercury, and always retains the property thus acquired.

The vitriolic acid does not diffolve bifmuth: Its proper folvent is the nitrous acid, which diffolves it with violence, and abundance of fumes.

Bifmuth diffolved in the nitrous acid is precipitated not only by alkalis, but even by the bare addition of water. This precipitate is extremely white, and known by the name of *magiftery of bifmuth*.

The acid of fea-falt and *aqua regis* likewife act upon bifmuth, but with lefs violence.

This femi-metal does not fenfibly deflagrate with nitre: yet it is quickly deprived of its phlogifton, and turned into a vitrifiable calx, when expofed with it to the action of fire.

It readily unites with fulphur in fufion, and forms therewith a compound which appears to confift of needles adhering laterally to each other.

It may be feparated from the fulphur with which it is combined, by only expofing it to the fire, without any additament; for the fulphur is either confumed or fublimed, and leaves the bifmuth behind.

Of Zinc.

Zinc to appearance differs but little from bifmuth, and has even been confounded with it by feveral authors. Neverthelefs, befides that it has fomething of a bluifh caft, and is harder than bifmuth, it differs from it effentially in its properties, as will prefently be fhewn. Thefe two metallic fubftances fcarce refemble each other in any thing, but the qualities common to all femi-metals.

Zinc melts the moment it grows red in the fire, and then alfo begins to turn to a calx, which, like any other metallic calx, may be reduced by means of the phlogifton: But if the fire be confiderably increafed, it fublimes, flames, and burns like an oily matter; which is a proof of the great quantity of phlogifton in its compofition. At the fame time abundance of flowers rife from it in the form of white flakes, flying about in the air like very light bodies; and into this form may the whole fubftance of the zinc be converted. Several names have been given to thefe flowers, fuch as *pompholix*, *philofophic wool*. They are fuppofed to be no other than the zinc itfelf deprived of its phlogifton; yet no body has hitherto been able to refufcitate them in the form of zinc, by reftoring their phlogifton according to the methods ufed in the reduction of metals. Though they rife in the air with very great eafe while the zinc is calcining, yet when once formed they are very fixed; for they withftand the utmoft violence of fire, and are capable of being vitrified, efpecially if joined with a fixed alkali. They are foluble in acids.

Zinc unites with all metalline fubftances, except bifmuth. It has this fingular property, that being mixed with copper, even in a confiderable quantity, fuch as a fourth part, it does not greatly leffen the ductility thereof, and at the fame time communicates to it a very beautiful colour not unlike that of gold: On which account the compofition is frequently made, and produces what is called *brafs*. This metal melts much more eafily than copper alone, becaufe of the zinc with which it is alloyed. If it be expofed to a great degree of heat, the zinc which it contains takes fire, and fublimes in white flowers, juft as when it is pure

It is to be obferved, that brafs is ductile only while it is cold, and not then unlefs the zinc ufed in making it was very pure; otherwife the compofition will prove but *tombac*, or *prince's metal*, having very little malleability.

Zinc is very volatile, and carries off with it any metallic fubftance with which it is fufed, making a kind of fublimate thereof. In the furnaces where they fmelt ores containing zinc, the matter thus fublimed is called *cadmia fornacum*, to diftinguifh it from the native cadmia called alfo *calamine*, or *lapis calaminaris*; which, properly fpeaking, is an ore of zinc, containing a great deal of that femi-metal, together with fome iron, and a ftony fubftance. The name of *cadmia fornacum* is not appropriated folely to the metallic fublimates procured by means of zinc, but is given in general to all the metallic fublimates found in fmelting-houfes.

If a violent and fudden heat be applied to zinc, it fublimes in its metalline form; there not being time for it to burn and be refolved into flowers.

This femi-metal is foluble in all the acids, but efpecially in fpirit of nitre, which attacks and diffolves it with very great violence.

Zinc has a greater affinity than iron or copper with the vitriolic acid; and therefore it decompounds the green and blue vitriols, precipitating thofe two metals

by uniting with the vitriolic acid, with which it forms a metallic ſalt or vitriol called *white vitriol*, or *vitriol of zinc*.

Nitre mixed with zinc, and projected into a red hot crucible, detonates with violence; and during the detonation there ariſes a great quantity of white flowers, like thoſe which appear when it is calcined by itſelf.

Sulphur has no power over zinc. Even liver of ſulphur, which diſſolves all other metallic ſubſtances, contracts no union with this ſemi-metal.

Of Regulus *of* Arsenic.

Regulus of arſenic is the moſt volatile of all the ſemi-metals. A very moderate heat makes it wholly evaporate, and fly off in fumes; on which account it cannot be brought to fuſion, nor can any conſiderable maſſes thereof be obtained. It has a metallic colour, ſomewhat reſembling lead; but ſoon loſes its ſplendor when expoſed to the air.

It unites readily enough with metallic ſubſtances, having the ſame affinities with them as regulus of antimony hath. It makes them brittle, and unmalleable. It hath alſo the property of rendering them volatile, and greatly facilitates their ſcorification.

It very eaſily parts with its phologiſton and metallic form. When expoſed to the fire it riſes in a kind of ſhining cryſtalline calx, which on that account looks more like a ſaline matter than a metallic calx. To this calx or theſe flowers are given the names of *white arſenic*, *cryſtalline arſenic*, and moſt commonly plain *arſenic*.

Arſenic differs from every other metalline calx, firſt, in being volatile; whereas the calxes of all other metallic ſubſtances, not excepting thoſe of the moſt volatile ſemi-metals, ſuch as regulus of antimony and zinc, are exceedingly fixed; and ſecondly, in having a ſaline character, which is not found in any other metalline calx.

The ſaline character of arſenic appears, firſt, from its being ſoluble in water; ſecondly, from its corroſive quality, which makes it none of the moſt violent poiſons: a quality from which the other metallic ſubſtances are free, when they are not combined with ſome ſaline matter. Regulus of antimony muſt however be excepted: but then the beſt chemiſts agree, that this ſemi-metal is either nearly of the ſame nature with arſenic, or contains a portion thereof in its compoſition: beſides its noxious qualities never diſcover themſelves ſo plainly as when it is combined with ſome acid. Laſtly, arſenic acts juſt like the vitriolic acid upon nitre; that is, it decompounds that neutral ſalt, by expelling its acid from its alkaline baſis, of which it takes poſſeſſion, and therewith forms a new ſaline compound.

This combination is a ſpecies of ſalt that is perfectly neutral. When the operation is performed in a cloſe veſſel, the ſalt ſhoots into cryſtals in the form of right-angled quadrangular priſms, terminated at each etremity by pyramids that are alſo quadrangular and right-angled; ſome of which, however, inſtead of ending in a point, are obtuſe as if truncated. The conſequence is different when the operation is performed in an open veſſel; for then nothing is obtained but an alkaline ſalt impregnated with arſenic, which cannot be cryſtallized.

The cauſe of this different effect is this: When the arſenic is once engaged in the alkaline baſis of the nitre, it can never be ſeparated from it by the utmoſt force of fire, ſo long as it is kept in a cloſe veſſel; whereas, if you expoſe it to the fire without that precaution, it readily ſeparates from it.

This ſalt poſſeſſes many ſingular properties, the chief of which are theſe: Firſt, it cannot be decompounded by the intervention of any acid, even the ſtrongeſt acid of vitriol; and this, joined to its property of expelling the nitrous acid from its baſis, ſhews that it has a very great affinity with fixed alkalis.

Secondly, this very ſalt, on which pure acids have no effect, is decompounded with the greateſt eaſe by acids united with metallic ſubſtances. The reaſon of this phenomenon is curious, and furniſhes us with an inſtance of what we advanced concerning double affinities.

If to a ſolution of any metallic ſubſtance whatever, made by any acid whatever, (except that of mercury by the marine acid, and that of gold by *aqua regis*,) a certain quantity of this ſalt diſſolved in water be added, the metallic ſubſtance is inſtantaneouſly ſeparated from the acid in which it was diſſolved, and falls to the bottom of the liquor.

All metallic precipitates obtained in this manner are found to be a combination of the metal with arſenic; whence it neceſſarily follows that the neutral ſalt is by this means decompounded, its arſenical part uniting with the metallic ſubſtance, and its alkaline baſis with the acid in which that ſubſtance was diſſolved.

The affinities of theſe ſeveral bodies muſt be conſidered as operating on this occaſion in the following manner: The acids which tend to decompound the neutral ſalt of arſenic, by virtue of their affinity with its alkaline baſis, are not able to accompliſh it, becauſe this affinity is powerfully counteracted by that which the arſenic has with the ſame alkaline baſis, and which is equal or even ſuperior to theirs. But if theſe acids happen to be united with a ſubſtance which naturally has a very great affinity with the arſenical part of the neutral ſalt, then, the two parts of which this ſalt conſiſts, being drawn different ways by two ſeveral affinities, tending to ſeparate them from each other, the ſalt will undergo a decompoſition, which could not have been effected without the help of this ſecond affinity. Now, as metallic ſubſtances have a great affinity with arſenic, it is not ſurpriſing that the neutral ſalt of arſenic, which cannot be decompounded by a pure acid, ſhould nevertheleſs yield to an acid combined with a metal. The decompoſition of this ſalt, therefore, and the precipitation which of courſe it produces in metallic ſolutions, are brought about by the means of a double affinity; namely, that of the acid with the alkaline baſis of the neutral ſalt, and that of the metal with the arſenical part of that ſalt.

Arſenic has not the ſame effect on ſea-ſalt as on nitre, and cannot expel its acid: a very ſingular phenomenon, for which it is hard to aſſign a reaſon; for the nitrous acid

acid is known to have a greater affinity than the marine acid with alkalis, and even with the basis of sea-salt itself.

Yet arsenic may be combined with the basis of sea-salt, and a neutral salt thereby obtained, like that which results from the decomposition of nitre by arsenic: but for that purpose a quadrangular nitre must be first prepared, and arsenic applied thereto as to common nitre.

The salt produced by uniting arsenic with the basis of sea-salt very much resembles the neutral salt of arsenic above treated of, as well in the figure of its crystals as in its several properties.

Arsenic presents another singular phenomenon, both with the alkali of nitre and with that of sea-salt; which is, that if it be combined with these salts in a fluid state, it forms with them a saline compound, quite different from the neutral salts of arsenic which results from the decomposition of nitrous salts.

This saline compound, called *liver of arsenic*, takes up a much greater quantity of arsenic than is necessary for the perfect saturation of the alkali. It has the appearance of a glue, which is so much the thicker the more arsenic it contains. Its smell is disagreeable; it attracts the moisture of the air, and does not crystallize; it is easily decompounded by any acid whatever, which precipitates the arsenic and unites with the alkali. Lastly, the effects it produces on metallic solutions are different from those of our neutral arsenical salts.

Arsenic is easily reduced to a regulus. It need only be mixed with any matter containing the phlogiston, and by the help of a moderate heat a true regulus will sublime. This regulus is very volatile, and calcines with the greatest ease; which is the reason why it cannot be obtained but in small quantities; and also why, in order to obtain masses of it, some have thought of adding thereto some metal with which it has a great affinity, such as copper or iron; because, by joining with the metal, it is partly fixed and restrained from flying off. But it is plain the regulus obtained by this means is not pure, as it must partake considerably of the metal employed.

Arsenic readily unites with sulphur, and rises with it in a yellow compound called *orpiment*.

Sulphur cannot be separated from arsenic but by the intervention of two bodies only; to wit, a fixed alkali and mercury.

The property which mercury possesses of separating sulphur from arsenic is founded on this, that these two metallic substances are incapable of contracting any union; whereas, though most of the other metals and semimetals have a greater affinity with sulphur than mercury hath, nevertheless they are all unable to decompound orpiment; because some of them have as great an affinity with arsenic as with sulphur; others have no affinity with either; and lastly, sulphur hath as great an affinity with arsenic as with any of them.

It must be observed, that, if fixed alkalis be employed to purify arsenic in this manner, no more must be used than is necessary to absorb the sulphur or the phlogiston, of which also it is their nature to deprive arsenic; for otherwise, as it has been shewn that arsenic readily unites with alkalis, they would absorb a considerable quantity thereof.

Of OIL *in general.*

OIL is an unctuous body, which burns and consumes with flame and smoke, and is not soluble in water. It consists of the phlogiston united with water by means of an acid. There is, moreover, in its composition a certain proportion of earth, more or less according to each several sort of oil.

The inflammability of oil evidently proves that it contains the phlogiston. That an acid is one of its constituent principles many experiments demonstrate, of which these are the chief: If certain oils be long triturated with an alkaline salt, and the alkali afterwards dissolved in water, crystals of a true neutral salt will be produced: some metals, and particularly copper, are corroded and rusted by oils, just as they are by acids: again, acid crystals are found in some oils that have been long kept. This acid in oil serves undoubtedly to unite its phlogiston with its water; because these two substances having no affinity with each other cannot be united without the intervention of such a medium as an acid, which has an affinity with both. As to the existence of water in oils, it appears plainly when they are decomposed by repeated distillations, especially after mixing them with absorbent earths. Lastly, when an oil is destroyed by burning, a certain quantity of earth is constantly left behind.

Oils exposed to the fire in close vessels pass over almost wholly from the containing vessel into any other applied to receive them. There remains, however, a small quantity of black matter, which is extremely fixed, and continues unalterable as long as it has no communication with the external air, be the force of the fire ever so violent. This matter is no other than part of the phlostiston of the oil united with its most fixed and grossest earth; and this is what we called *charcoal*, or plainly a *coal*.

Of CHARCOAL.

WHEN oil happens to be united to much earth, as it is in vegetable and animal bodies, it leaves a considerable quantity of *coal* or charred matter.

This coal, exposed to the fire in the open air, burns and wastes, but without blazing like other combustible matters: there appears only a small bluish flame, but not the least smoke. Most commonly it only glows and sparkles, and so gradually falls into ashes, which are nothing but the earth of the body combined with an alkaline salt in burning. This alkaline salt may be separated from the earth, by lixiviating the ashes with water, which dissolves all the salt, and leaves the earth quite pure.

Charcoal is unalterable and indestructible by any other body but fire; whence it follows, that when it is not actually kindled and ignited, the most powerful agents, such as the acids, though ever so strong and concentrated, have not the least effect on it.

The case is otherwise when it is lighted, that is, when its phlogiston begins to separate from its earth; for then the pure acid of vitriol being joined therewith contracts

an

an inftantaneous union with its phlogifton, and evaporates in a volatile fulphureous fpirit. If the vitriolic acid, inftead of being applied quite pure, be firft clogged with fome bafis, efpecially an alkaline one, it quits that bafis, enters into a more intimate union with the phlogifton of the burning coal, and fo forms an actual fulphur, with which the alkali now unites and forms a hepar.

The pure acid fea-falt hath not been obferved to act in the leaft upon charcoal, efpecially when it is not on fire. But when this acid is incorporated with an alkaline or metallic bafis, and combined according to a peculiar procefs with burning charcoal, it in like manner quits its bafis, unites with the phlogifton, and therewith forms a phofphorus.

Nor has the pure nitrous acid any effect on a charred coal, even when ignited: and fo far is it from being able to kindle a cold one, that when poured on a live one, it extinguifhes it like water. But when this acid is united with a bafis, it quits it rapidly as foon as it touches a burning coal, and rufhes violently into an union with the phlogifton thereof. From this union there probably arifes, as we faid before, a kind of fulphur or phofphorus, which is fo inflammable as to be deftroyed by the fire the very moment it is generated.

The acids of nitre and vitriol act upon oils; but very differently, according to the quantity of phlegm they contain. If they be awakened with much water, they have no effect at all upon oils: if they contain little water, or be dephlegmated to a certain degree, they diffolve them with heat, and with them form compounds of a thick confiftence. Acids thus combined in a confiderable proportion with oils render them foluble in water.

Of Soap.

Alkalis alfo have the fame property. When an oil is combined with an acid, or an alkali, in fuch a manner that the compound refulting from their union is foluble in water; fuch a compound may in general be called *foap*. Soap itfelf hath the property of rendering fat bodies in fome meafure foluble in water; on which account it is very ufeful for fcouring or cleanfing any thing greafy.

Oily and faline fubftances, combined together, obferve the fame general rules as all other combinations; that is, they mutually communicate the properties belonging to each: thus oils, which naturally are not foluble in water, acquire by their union with faline matters the property of diffolving therein; and falts lofe by their conjunction with oils part of their natural tendency to incorporate with water; fo that while they ferve to conftitute foap, they do not, as before, attract the moifture of the air, *&c.* and in like manner, as they are not inflammable, they confiderably leffen the inflammability of the oils combined with them.

Acid foaps are decompounded by alkalis, as alkaline foaps are by acids, according to the general rules of affinities.

The acids of nitre and vitriol, when highly concentrated, diffolve oils with fuch violence as to heat them, make them black, burn them, and even fet them on fire. How fea-fealt affects oils is not yet fufficiently afcertained.

All oils have the property of diffolving fulphur; which is not at all furprifing, feeing each of its component principles hath an affinity with oil.

It is alfo a property common to all oils to become more fluid, fubtile, light, and limpid, the oftener they are diftilled. On the contrary, by being incorporated with faline fubftances they acquire a greater confiftence, and fometimes form compounds that are almoft folid.

Of the feveral forts of Oils.

Oils are diftinguifhed by the fubftances from which they are drawn: and as oils are extracted from minerals, from vegetables, and from animals, there are of courfe mineral, vegetable, and animal oils.

Of Mineral Oils.

In the bowels of the earth we find but one fort of oil, called *petroleum*: Its fmell is ftrong, and not difagreeable, and its colour fometimes more, fometimes lefs yellow. There are certain mineral fubftances which yield by diftillation a great deal of oil very like petroleum. This fort of fubftance is called a *bitumen*, and is, indeed, nothing but an oil rendered confiftent and folid by being combined with an acid; as appears from hence, that, by uniting petroleum with the acid of vitriol, we can produce an artificial bitumen very like the native.

Of Vegetable Oils.

Vegetable fubftances yield a very great quantity and variety of oils; for there is not a plant, or part of a plant, that does not contain one or more forts thereof, generally peculiar to itfelf, and different from all others.

By expreffion only, that is, by bruifing and fqueezing vegetable fubftances, particularly certain fruits and feeds, a fort of oil is obtained which has fcarce any fmell or tafte. Oils of this fort are very mild and unctuous; and, becaufe in this refpect they refemble animal fat more than the reft do; they are called *fat oils*.

Thefe oils, being expofed to the air for fome time, fooner or later grow thick, acquire an acrid tafte, and a ftrong difagreeable fmell. Some of them congeal with the fmalleft degree of cold. This fort of oil is well adapted to diffolve thofe preparations of lead called litharge and minium, with which they form a thick tenacious fubftance, that is ufed for the bafis of almoft all plaifters. They alfo diffolve lead in its metalline form, but not fo eafily as the forts of calx above-mentioned; probably becaufe its body is not fo much opened, nor its parts fo divided.

By expreffion alone we alfo procure from certain vegetable fubftances another fort of oil, which is thin, limpid, volatile, of a pungent tafte, and retains the fmell of the vegetable that yielded it; on which account it is called an *effential oil*. Of this there are feveral forts, differing from one another, like the fat oils, according to the fubjects from which they are obtained.

We muft obferve, that it is very difficult, or rather in moft cafes impoffible, to force from the greateft part of vegetables, by expreffion only, all the effential oil they contain.

contain. For this purpofe, therefore, recourfe muft be had to fire: a gentle heat, not exceeding that of boiling water, will extract all the effential oils of a vegetable; and this is the moft ufual and moft convenient way of procuring them.

The fat oils cannot be obtained by the fame method: thefe being much lefs volatile than the effential oils, require a much greater degree of heat to raife them; which, neverthelefs, they cannot bear without being much fpoiled and entirely changed in their nature, as fhall prefently be fhewn. All oils, therefore, which rife with the heat of boiling water, and fuch alone, fhould be called effential oils.

Effential oils, in a longer or fhorter time, according to the nature of each, lofe the fragrant fmell they had when newly diftilled, and acquire another which is ftrong, rancid, and much lefs agreeable: They alfo lofe their tenuity, becoming thick and vifcid; and in this ftate they greatly refemble thofe fubftances abounding in oil which flow from certain trees, and which are called *balfams* or *refins*, according as they are lefs or more confiftent.

Balfams and refins are not foluble in water. But there are other oily compounds which likewife run from trees; and, though not unlike refins, are however foluble in water. Thefe are called *gums*; and their property of diffolving in water arifes from their containing more water and more falt than refins have; or at leaft their faline parts are lefs clogged and more difengaged.

Balfams and refins diftilled with the heat of boiling water yield great quantities of a limpid, fubtile, odoriferous, and, in one word, effential oil. In the ftill there remains a fubftance thicker and more confiftent than the balfam or refin was before diftillation. The fame thing happens to effential oils which by length of time have acquired a confiftence, and are grown refinous. If they be rediftilled, they recover their former tenuity, leaving behind them a remainder thicker and more refinous than they themfelves were. This fecond diftillation is called the *rectification* of an oil.

It muft be obferved, that an effential oil, combined with an acid ftrong enough to diffolve it, immediately becomes as thick and refinous, in confequence of this union, as if it had been long expofed to the air; which proves the confiftence an oil acquires by long keeping to be owing to this, that its lighteft and lefs acid parts being evaporated, the proportion of its acid to the remainder is fo increafed, that it produces therein the fame change as an additional acid mixed with the oil would have wrought before the evaporation.

This alfo fhews us, that balfams and refins are only effential oils combined with a great proportion of acid, and thereby thickened.

If vegetable fubftances, from which no more effential oil can be drawn by the heat of boiling water, be expofed to a ftronger heat, they yield an additional quantity of oil; but it is thicker and heavier than the effential oil. Thefe oils are black, and have a very difagreeable burnt fmell, which hath made them be called *fetid*, or *empyreumatic* oils. They are moreover very acrid.

It muft be obferved, that if a vegetable fubftance be expofed to a degree of heat greater than that of boiling water, before the fat or the effential oil is extracted from it, an empyreumatic oil only will then be obtained; becaufe both the fat and effential oils, when expofed to the force of fire, are thereby burnt, rendered acrid, acquire a fmell of the fire, and, in a word, become truly empyreumatic. There is ground to think, that an empyreumatic oil is nothing elfe but an effential or fat oil burnt and fpoiled by the fire, and that no other oil befides thefe two exifts naturally in vegetables.

Empyreumatic oils, diftilled and rectified feveral times by a gentle heat, acquire by every diftillation a greater degree of tenuity, lightnefs, and limpidity. By this means alfo they lofe fomething of their difagreeable odour; fo that they gradually come nearer and nearer to the nature of effential oils: and if the rectifications be often enough repeated, ten or twelve times for inftance, they become perfectly like thofe oils; except that their fmell will never be fo agreeable, nor like that of the fubftances from which they were obtained.

Fat oils may alfo be brought by the fame means to refemble effential oils: but neither effential nor empyreumatic oils are capable of acquiring the properties of fat oils.

Of Animal Oils.

Distillation procures us confiderable quantities of oil from all the parts of animal bodies, and efpecially from their fat. This oil at firft is not very fluid, and is extremely fetid; but by many rectifications it gradually acquires a great degree of clearnefs and tenuity, and at the fame time lofes much of its difagreeable odour.

Of Fermentation *in general.*

By fermentation is meant an inteftine motion, which, arifing fpontaneoufly among the infenfible parts of a body, produces a new difpofition and a different combination of thofe parts.

To excite a fermentation in a mixt body, it is neceffary, firft, that there be in the compofition of that mixt a certain proportion of watery, faline, oily, and earthy parts; but this proportion is not yet fufficiently afcertained. Secondly, it is requifite that the body to be fermented be placed in a certain degree of temperate heat; for much cold obftructs fermentation, and too much heat decompofes bodies. Laftly, the concurrence of the air is alfo neceffary to fermentation.

All vegetable and animal fubftances are fufceptible of fermentation, becaufe all of them contain in a due proportion the principles above fpecified. However, many of them want the proper quantity of water, and cannot ferment while they remain in fuch a ftate of drinefs. But it is eafy to fupply that defect.

With refpect to minerals properly fo called, they are not fubject to any fermentation, at leaft that our fenfes can perceive.

There are three forts of fermentation, diftinguifhed from one another by their feveral productions. The firft produces wines and fpiritous liquors; for which reafon it is called the *vinous* or *fpirituous fermentation*: The refult of the fecond is an acid liquor; and therefore it is called

called the *acetous fermentation:* and the third generates an alkaline falt; which, however, differs from the alkaline falts hitherto treated of, in this refpect chiefly, that, inftead of being fixed, it is extremely volatile: This laft fort takes the name of the *putrid* or *putrefactive fermentation*. We fhall now confider thefe three forts of fermentation and their effects a little more particularly.

Thefe three forts of fermentation may take place fucceffively in the fame fubject; which proves them to be only three different degrees of fermentation, all proceeding from one and the fame caufe. Thefe degrees of fermentation always follow the order in which we have here placed them.

Of the SPIRITUOUS, *or* VINOUS FERMENTATION.

THE juices of almoft all fruits, all faccharine vegetable matters, all farinaceous feeds and grains of every kind, being diluted with a fufficient quantity of water, are proper fubjects of fpirituous fermentation. If fuch liquors be expofed, in veffels flightly ftopped, to a moderate degree of heat, they begin in fome time to grow turbid; there arifes infenfibly a fmall commotion among their parts, attended with a hiffing noife; this by little and little increafes, till the groffer parts appear, like little feeds or grains, moving to and fro, agitated among themfelves, and thrown up to the furface. At the fame time fome air-bubbles rife, and the liquor acquires a pungent, penetrating fmell, occafioned by the very fubtile vapours which exhale from it.

Thefe vapours have never yet been collected, in order to examine their nature; and they are known only by their noxious effects. They are fo actively pernicious, that if a man comes rafhly into a clofe place, where large quantities of liquors are fermenting, he fuddenly drops down and expires, as if he were knocked on the head.

When thefe feveral phenomena begin to go off, it is proper to ftop the fermentation, if a very fpirituous liquor be required: for if it be fuffered to continue longer, the liquor will become acid, and from thence proceed to its laft ftage, that is, to putrefaction. This is done by ftopping the containing veffels very clofe, and removing them into a cooler place. Then the impurities precipitate, and fettling at the bottom leave the liquor clear and tranfparent: And now the palate difcovers that the fweet faccharine tafte it had before fermentation is changed to an agreeable pungency which is not acid.

Liquors thus fermented are in general called *wines:* For though in common life that word properly fignifies the fermented juice of grapes only, and particular names are given to the fermented juices of other vegetable fubftances, as that obtained from apples, is called *cyder*; that made from malt is called *beer*; yet in chemiftry it is of ufe to have one general term denoting every liquor that has undergone this firft degree of fermentation.

By diftillation we draw from wine an inflammable liquor, of a yellowifh white colour, light, and of a penetrating pleafant fmell. This liquor is the truly fpirituous part of the wine, and the product of fermentation. That which comes off in the firft diftillation is commonly loaded with much phlegm and fome oily parts, from which it may be afterwards freed. In this ftate it goes by the name of *brandy*; but, when freed from thefe heterogeneous matters by repeated diftillations, it becomes ftill clearer, lighter, more fragrant, and much more inflammable, and then is called *fpirit of wine*, and *rectified fpirit of wine*, or *ardent fpirits*, if confiderably purified. The properties which diftinguifh an ardent fpirit from all other fubftances are, its being inflammable; its burning and confuming entirely, without the leaft appearance of fmoke or fuliginofity; its containing no particles reducible to a coal; and its being perfectly mifcible with water. Ardent fpirits are lighter and more volatile than any of the principles of the mixts from which they were produced, and confequently more fo than the phlegm, the acid, and the oil of which they themfelves confift. This arifes from a particular difpofition of thefe principles, which are in a fingular manner attenuated by fermentation, and thereby rendered more fufceptible of expanfion and rarefaction.

Ardent fpirits are fuppofed to be the natural folvents of oils and oily matters. But it is very remarkable, that they diffolve effential oils only, without touching the fat of animals, or the fat oils obtained from vegetables by expreffion; yet when thefe oils have once undergone the action of fire, they become foluble in fpirit of wine, and even acquire a new degree of folubility every time they are diftilled. It is not fo with effential oils, which can never be rendered more foluble in ardent fpirits than they are at firft; and are fo far from acquiring a new degree of folubility every time they are diftilled, that on the contrary they even in fome meafure lofe that property by repeated rectifications.

Spirit of wine doth not diffolve fixed alkalis; or at leaft it takes up but a very fmall quantity thereof; and hence ardent fpirits may be freed from much of their phlegm by means of thefe falts thoroughly dried: For as they ftrongly imbibe moifture, and have even a greater affinity than ardent fpirits with water, if a fixed alkali well exficcated be mixed with fpirit of wine that is not perfectly dephlegmated, the alkali immediately attracts its fuperfluous moifture, and is thereby refolved into a liquor, which on account of its gravity defcends to the bottom of the veffel. The fpirit of wine, which fwims a-top, is by this means as much dephlegmated, and as dry, as if it had been rectified by feveral diftillations. As it takes up fome alkaline particles in this operation, it is thereby qualified to diffolve oily matters with the greater facility. When rectified in this manner, it is called *tartarifed fpirit of wine*.

Yet fpirit of wine, even when rectified to an alcohol, is not capable of diffolving all oily matters. Thofe named gums will by no means enter into any fort of union therewith; but it readily diffolves moft of thofe which are known by the appellation of refins. When it has diffolved a certain proportion of refinous particles, it acquires a greater confiftence, and forms what is called a *fpirit varnifh*, or a *drying varnifh*, becaufe it foon dries. This varnifh is fubject to be damaged by water. Many forts thereof are prepared, different from each other according to the different refins employed, or the propor-

tions

tions in which they are ufed. Moft of thefe varnifhes are tranfparent and colourlefs.

Such bitumens or refins as fpirit of wine will not touch are diffolved in oils by means of fire, and then form another kind of varnifh which water does not hurt. Thefe varnifhes are ufually coloured, and require much longer time to dry than the fpirit-varnifhes: They are called *oil-varnifhes*.

Spirit of wine hath a much greater affinity with water than with oily matters; and therefore if a folution of any oil or refin in fpirit of wine be mixed with water, the liquor immediately grows turbid, and acquires a whitifh milky colour, owing entirely to the oily parts being feparated from the fpirituous menftruum by the acceffion of water, and too finely divided to appear in their natural form. But if the liquor ftands fome time quiet, feveral of thefe particles unite together, and gradually acquire a bulk fufficient to render them very perceptible to the eye.

Acids have an affinity with fpirit of wine, and may be combined with it. By this union they lofe moft of their acidity, and on that account are faid to be *dulcified*.

One part of highly concentrated oil of vitriol being mixed with four parts of well dephlegmated fpirit of wine, there arifes immediately a confiderable ebullition and effervefcence, attended with great heat, and abundance of vapours, which fmell pleafantly, but are hurtful to the lungs. At the fame time is heard a hiffing like that produced by a piece of red-hot iron plunged in water. Indeed it is proper to mix the liquors very gradually; for otherwife the veffels in which the operation is performed will be in great danger of breaking.

If two liquors thus mixed be diftilled with a very gentle heat, there rifes firft a fpirit of wine of a moft penetrating and grateful odour: When about half thereof is come over, what follows has a quicker and more fulphureous fmell, and is alfo more loaded with phlegm. When the liquor begins to boil a little, there comes off a phlegm which fmells very ftrong of fulphur, and grows gradually more acid. On this phlegm floats a fmall quantity of a very light and very limpid oil. In the ftill there remains a thick, blackifh fubftance, fomewhat like a refin or bitumen. From this fubftance may be feparated a good deal of a vitriolic but fulphureous acid. When that is extracted, there remains a black mafs like a charred coal, which, being put into a crucible, and expofed to a violent heat, leaves a fmall portion of earth, very fixed, and even vitrifiable.

By rectifying the ardent fpirit, which came over in diftilling the above-mentioned mixture, a very fingular liquor is obtained, which differs effentially both from oils and from ardent fpirits, though in certain refpects it refembles them both. This liquor is known in chemiftry by the name of *æther*, and its chief properties are as follows.

Æther is lighter, more volatile, and more inflammable, than the moft highly rectified fpirit of wine. It quickly flies off when expofed to the air, and fuddenly catches fire when any flame approaches it. It burns like fpirit of wine without the leaft fmoke, and confumes entirely without leaving the fmalleft appearance of a coal or of afhes. It diffolves oils and oily matters with great eafe and rapidity. Thefe properties it has in common with an ardent fpirit. But it refembles an oil, in that it is not mifcible with water; and this makes it effentially different from fpirit of wine, the nature of which is to be mifcible with all aqueous liquors.

Another very fingular property of æther is its great affinity with gold, exceeding even that of *aqua regis*. It does not indeed diffolve gold when in a mafs, and in its metalline form: But if a fmall quantity of æther be added to a folution of gold in *aqua regis*, and the whole fhaken together, the gold feparates from the *aqua regis*, joins the æther, and remains diffolved therein.

The reafon of all the phenomena above-mentioned, refulting from the mixture of fpirit of wine with oil of vitriol, is founded on the great affinity between this acid and water. For if the vitriolic acid be weak, and as it were over-dofed with watery parts, neither oil nor æther can be obtained by means thereof: But when highly concentrated, it attracts the aqueous parts very powerfully; and therefore being mixed with fpirit of wine, lays hold of moft of the water contained in it, and even robs it of fome portion of that which is effential to its nature, and neceffary to conftitute it fpirit of wine: Whence it comes to pafs, that a certain quantity of the oily particles in its compofition being feparated from the watery particles, and fo brought nearer to each other, they unite and affume their natural form; and thus the oil that fwims at top of the fulphureous phlegm is produced.

The vitriolic acid moreover thickens and even burns fome of this oil; and hence comes the bituminous refiduum left at the bottom of the ftill, which looks like the refult of a vitriolic acid combined with common oil. Laftly, the vitriolic acid becomes fulphureous, as it always doth when united with oily matters, and alfo very aqueous, on account of the quantity of phlegm which it attracts from the fpirit of wine.

Æther may be confidered as a fpirit of wine exceedingly dephlegmated, even to fuch a degree that its nature is thereby changed; fo that the few aqueous particles left in it are not fufficient to diffolve the oily particles and keep them afunder; which therefore being now much nearer to one another than in common fpirit of wine, the liquor hath loft its property of being mifcible with water.

Spirit of nitre, well dephlegmated, and combined with fpirit of wine, prefents likewife fome very fingular appearances.

Firft, in the very inftant of its mixture with fpirit of wine, it produces a greater and more violent effervefcence than the vitriolic acid occafions.

Secondly, this mixture, without the help of diftillation, and only by ftopping the bottle in which the liquors are contained, affords a fort of æther, produced probably by the vapours which afcend from, and fwim atop of the mixture.

Thirdly, fome authors pretend, that by diftilling the mixture under confideration an oil is obtained greatly refembling that which rifes from fpirit of wine combined with vitriolic acid.

Fourthly, the two liquors we are fpeaking of, being intimately

intimately mixed by diſtillation, form a liquor ſlightly acid, uſed in medicine, and known by the name of *ſweet* or *dulcified ſpirit of nitre:* a very proper name, ſeeing the nitrous acid, by uniting with the ſpirit of wine, actually loſes almoſt all its acidity and corroſive quality.

Fifthly, when the diſtillation is finiſhed, there remains in the bottom of the veſſel a thick, blackiſh ſubſtance, nearly reſembling that which is found after diſtilling oil of vitriol and ſpirit of wine.

Spirit of ſalt hath likewiſe been combined with ſpirit of wine; but it does not unite therewith ſo eaſily or ſo intimately as the two acids above mentioned. To mix them thoroughly, the ſpirit of ſalt muſt be highly concentrated, and ſmoking; and moreover the aſſiſtance of the ſtill muſt be called in. Some authors pretend, that from this mixture alſo a ſmall quantity of oil may be obtained; which probably happens when the liquors have the qualities above ſpecified. The marine acid likewiſe, by uniting with ſpirit of wine, loſes moſt of its acidity; on which account it is in like manner called *ſweet* or *dulcified ſpirit of ſalt.* A thick reſiduum is alſo found here after diſtillation.

Of the Acetous Fermentation.

Besides an ardent ſpirit, wine affords a great deal of water, oil, earth, and a ſort of acid which ſhall be conſidered preſently. When the ſpirituous part is ſeparated from theſe other matters, they undergo no further change. But if all the conſtituent parts of wine remain combined together, then, after ſome time, ſhorter or longer as the degree of heat in which the wine ſtands is greater or leſs, the fermentation begins afreſh, or rather arrives at its ſecond ſtage. The liquor once more grows turbid, a new inteſtine motion ariſes, and after ſome days it is found changed into an acid; which, however, is very different from thoſe hitherto treated of. The liquor then takes the name of *vinegar.* The acetous fermentation differs from the ſpirituous, not only in its effect, but alſo in ſeveral of its concomitant circumſtances. Moderate motion is of ſervice to this, whereas it obſtructs the ſpirituous; and it is attended with much more warmth than the ſpirituous. The vapours it produces are not noxious, like thoſe of fermenting wine, Laſtly, Vinegar depoſites no tartar, even when the wine employed in this operation is quite new, and hath not had time to diſcharge its tartar: inſtead of tartar, vinegar depoſites a viſcid matter which is very apt to putrify.

Of Vinegar.

If wine, which has gone through this ſecond ſtage of fermentation, be diſtilled, inſtead of an ardent ſpirit, only an acid liquor is obtained, which is called *diſtilled vinegar.*

This acid has the ſame properties as the mineral acids; that is, it unites with alkaline ſalts, abſorbent earths, and metallic ſubſtances, and therewith forms neutral ſaline combinations.

Its affinity with theſe ſubſtances obſerves the ſame order as that obſerved by the mineral acids with regard to the ſame ſubſtances; but in general it is weaker; that is, any mineral acid is capable of expelling the acid of vinegar out of all matters with which it is united.

Vinegar hath likewiſe a greater affinity than ſulphur with alkalis: whence it follows, that it is capable of decompounding that combination of ſulphur with an alkali called liver of ſulphur, and of precipitating the ſulphur it contains.

The acid of vinegar is always clogged with a certain proportion of oily parts, which greatly weaken it, and deprive it of much of its activity; and for this reaſon it is not near ſo ſtrong as the mineral acids, which are not entangled with any oil. By diſtillation, indeed, it may be freed from this oil, and at the ſame time from the great quantity of water which in a manner ſuffocates it, and by that means may be brought much nearer to the nature of the mineral acids: but this attempt hath not yet been proſecuted with the aſſiduity it deſerves. Beſides diſtillation, there is another way of freeing vinegar from a good deal of its phlegm; and that is, by expoſing it to a hard froſt, which readily congeals the watery part into ice, while the acid retains its fluidity.

Vinegar, ſaturated with a fixed alkali, forms a neutral oily ſalt, of a dark colour, which is ſemi-volatile, melts with a very gentle heat, flames when thrown upon burning coals, and diſſolves in ſpirit of wine, of which, however, it requires ſix parts to complete the ſolution. This ſolution being evaporated to drineſs leaves a matter in the form of leaves lying on each other; on which account it hath obtained the name of *terra foliata.* The ſame foliated matter will be obtained, though the ſalt be not previouſly diſſolved in ſpirit of wine; but not ſo readily. This ſalt is alſo called *regenerated tartar.* Under the head of tartar we ſhall ſee the reaſon of theſe different appellations. Regenerated tartar is alſo in ſome degree capable of cryſtallizing: for th s purpoſe a reſolution thereof in water muſt be ſlowly evaporated to the conſiſtence of a ſyrup, and then ſuffered to ſtand quiet in a cool place; by which means it will ſhoot into cluſters of cryſtals, lying one upon another, not unlike the feathers on a quill.

With vinegar and ſeveral abſorbent earths, ſuch as calcined pearls, coral, ſhells of fiſh, *&c.* are alſo formed neutral ſaline compounds, each of which take the name of the particular earth employed in its compoſition.

Vinegar perfectly diſſolves lead, and converts it to a neutral metallic ſalt, which ſhoots into cryſtals, and has a ſweet ſaccharine taſte. This compound is called *ſugar of lead*, or *ſal Saturni.*

If lead be expoſed to the bare vapour of vinegar, it will be thereby corroded, calcined, and converted into a white matter much uſed in painting, and known by the name of *ceruſe*, or, when it is finer than ordinary, *white-lead.*

Vinegar corrodes copper likewiſe, and converts it into a beautiful green ruſt, which alſo is uſed in painting, and diſtinguiſhed by the name of *verdegris.* However, vinegar is not commonly employed to make verdegris: for this purpoſe they uſe wine, or the rape of wine, from which fire extricates an acid analogous to that of vinegar.

Of Tartar.

This ſubſtance is a ſaline compound, conſiſting of earthy, oily, and eſpecially acid parts. It is found in the form of cruſts, adhering to the inner ſides of veſſels in which wines have ſtood for ſome time, particularly acid wines, ſuch as thoſe of Germany.

Tartar derives its origin from the ſuperabundant quantity of the acid contained in the juice of the grape. This ſuperfluous acid, being more than is requiſite to conſtitute the ardent ſpirit, unites with ſome of the oil and earth contained in the fermented liquor, and forms a kind of ſalt; which for ſome time continues ſuſpended in that liquor, but, when the wine ſtands undiſturbed in a cool place, is depoſited, as hath been ſaid, on the ſides of the caſk.

When it is purified, there appears on the ſurface of the liquor a ſort of white cryſtalline pellicle, which is ſkimmed off as it forms. This matter is called *cream of tartar*. The ſame liquor which produces this cream, and in which the purified tartar is diſſolved, being ſet to cool, yields a great number of white ſemi-tranſparent cryſtals, which are called *cryſtals of tartar*. The cream and the cryſtals of tartar are therefore no other than purified tartar, and differ from each other in their form only.

Though the cryſtals of tartar have every appearance of a neutral ſalt, yet they are far from being ſuch; for they have all the properties of a true acid, which ſcarce differs from that of vinegar, except that it contains leſs water, and more earth and oil; to which it owes its ſolid form, as well as its property of not being ſoluble in water without much difficulty: for a very great quantity of water is requiſite to keep the cryſtals of tartar in ſolution; and it muſt moreover be boiling hot; otherwiſe as ſoon as it cools moſt of the tartar diſſolved in it ſeparates from the liquor, and falls to the bottom in the form of a white powder.

Tartar is decompoſed by calcination in the open fire. All its oily parts are conſumed or diſſipated in ſmoke, together with moſt of its acid. The other part of its acid, uniting intimately with its earth, forms a very ſtrong and very pure fixed alkali, called *ſalt of tartar*.

It will be ſhewn in its proper place, that almoſt every vegetable matter, as well as tartar, leaves a fixed alkali in its aſhes: yet tartar has theſe peculiar properties; firſt, it aſſumes an alkaline character even when burnt or calcined in cloſe veſſels, whereas other ſubſtances acquire it only by being burnt in the open air; ſecondly, the alkali of tartar is ſtronger and more ſaline than almoſt any that is obtained from other matters.

This alkali, when thoroughly calcined, powerfully attracts the moiſture of the air, and melts into an unctuous alkaline liquor, improperly called *oil of tartar per deliquium*. This is the alkali generally uſed in making the *terra foliata*, mentioned under the head of vinegar; for which reaſon this combination is called *terra foliata tartari*.

Cryſtals of tartar combined with alkali of tartar produce a great effervеſcence while they are mixing, as all acids uſually do; and if the combination be brought exactly up to the point of ſaturation, a perfectly neutral ſalt is formed, which ſhoots into cryſtals, and eaſily diſſolves in water; and this hath procured it the name of *ſoluble tartar*. It is alſo called the *vegetable ſalt*, as being obtained from vegetables only; and again *tartariſed tartar*, becauſe it conſiſts of the acid and the alkali of tartar combined together.

Cryſtals of tartar combined with alkalis procured from the aſhes of ſea-weeds, ſuch as ſoda, which alkalis reſemble the baſis of ſea-ſalt, form likewiſe a neutral ſalt, which cryſtallizes well, and diſſolves eaſily in water. This ſalt is another ſort of ſoluble tartar. It is called *Saignette's ſalt*, from the inventor's name.

Tartar likewiſe diſſolves the abſorbent earths, as lime, chalk, *&c.* and with them forms neutral ſalts which are ſoluble in water. It even attacks metallic bodies, and when combined with them becomes ſoluble. A ſoluble tartar for medical uſe is prepared with cryſtals of tartar and iron: the metallic ſalt thereby produced hath the name of *chalybeated ſoluble tartar*. This ſalt attracts the moiſture of the air, and is one of thoſe which do not cryſtallize.

Cryſtallized tartar acts alſo upon ſeveral other metallic ſubſtances: for inſtance, it diſſolves the regulus, liver, and glaſs of antimony, and thence acquires an emetic quality: It is then called *ſtibiated*, or *emetic tartar*. It likewiſe diſſolves lead, and therewith forms a ſalt which, in the figure of its cryſtals, reſembles tartariſed tartar.

It is very extraordinary, that tartar, which of itſelf is not ſoluble in water, ſhould be ſoluble therein when become a neutral ſalt by uniting either with alkalis or with abſorbent earths, or even with metals. All the ſoluble tartars are eaſily decompounded by expoſing them to a certain degree of heat. In diſtillation they yield the ſame principles which are obtained from tartar; and what remains fixed in the fire, after they are thoroughly burnt, is a compound of the alkali which tartar naturally produces, and of the alkaline or metallic ſubſtance with which it was converted into a neutral ſalt

As cryſtal of tartar is the weakeſt of all acids, on account of the oily and earthy matters with which it is combined, ſoluble tartars are decompounded by all the acids; by any of which cryſtal of tartar may be ſeparated from the ſubſtance that ſerves it for a baſis and renders it a neutral ſalt.

Of the Putrid Fermentation, or Putrefaction.

Every body which hath gone through the two ſtages of fermentation above deſcribed, that is, the ſpirituous and the acetous fermentation, being left to itſelf in a due degree of warmth, which varies according to the ſubject, advances to the laſt ſtage of fermentation; that is, to putrefaction.

When a body is in a putrefying ſtate, it is eaſy to diſcover, by the vapours which riſe from it, by the opacity which invades it, if a pellucid liquor, and frequently even by a greater degree of heat than is found in the two other ſorts of fermentation, that an inteſtine motion is begun among its conſtituent parts, which laſts till the whole be entirely putrefied.

The effect of this inteſtine motion is to break the union,

union, and change the difpofition, of the particles conftituting the body in which it is excited, and to produce a new combination.

If we examine a fubftance that has undergone putrefaction, we fhall foon perceive that it contains a principle which did not exift in it before. If this fubftance be diftilled, there rifes firft, by means of a very gentle heat, a faline matter which is exceedingly volatile, and affects the organ of fmelling brifkly and difagreeably. Nor is the aid of diftillation neceffary to difcover the prefence of this product of putrefaction: it readily manifefts itfelf in moft fubftances where it exifts, as any one may foon be convinced by obferving the different fmell of frefh and of putrefied urine; for the latter not only affects the nofe, but even makes the eyes fmart, and irritates them fo as to draw tears from them in abundance.

This faline principle, which is the product of putrefaction, when feparated from the other principles of the body which affords it, and collected by itfelf, appears either in the form of a liquor, or in that of a concrete falt, according to the different methods ufed to obtain it. In the former ftate it is called a *volatile urinous fpirit*; and in the latter a *volatile urinous falt*. The qualification of urinous is given it, becaufe a great deal thereof is generated in putrefied urine, to which it communicates its fmell. It goes alfo by the general name of a *volatile alkali*, whether in a concrete or in a liquid form. The enumeration of its properties will fhew why it is called an alkali.

Volatile alkalis, from whatever fubftance obtained, are all alike, and have all the fame properties; differing only according to their degrees of purity. The volatile alkali, as well as the fixed, confifts of a certain quantity of acid combined with, and entangled by a portion of the earth of the mixt body from which it was obtained; and on that account it has many properties like thofe of a fixed alkali. But there is moreover in its compofition a confiderable quantity of a fat or oily matter, of which there is none in a fixed alkali; and on this account again there is a great difference between them. Thus the volatility of the alkali produced by putrefaction, which is the principal difference between it and the other kind of alkali, whofe nature it is to be fixed, muft be attributed to the portion of oil which it contains: for there is a certain method of volatilizing fixed alkalis by means of a fatty fubftance.

Volatile alkalis have a great affinity with acids, unite therewith rapidly, and with ebullition, and form with them neutral falts, which fhoot into cryftals, but differ from one another according to the kind of acid employed in the combination.

The neutral falts which have a volatile alkali for their bafis are in general called *ammoniacal falts*. That whofe acid is the acid of fea-falt is called *fal ammoniac*. As this was the firft known, it gave name to all the reft. Great quantities of this falt are made in Egypt, and thence brought to us. They fublime it from the foot of cow's-dung, which is the fuel of that country, and contains fea-falt, together with a volatile alkali, or at leaft the materials proper for forming it; and confequently all the ingredients that enter into the compofition of fal ammoniac.

The neutral falts formed by combining the acids of nitre and of vitriol with a volatile alkali, are called, after their acids, *nitrous fal ammoniac*, and *vitriolic fal ammoniac*: The latter, from the name of its inventor, is alfo called Glauber's *fecret fal ammoniac*.

A volatile alkali, then, has the fame property as a fixed alkali with regard to acids; yet they differ in this, that the affinity of the former with acids is weaker than that of the latter: and hence it follows, that any fal ammoniac may be decompounded by a fixed alkali, which will lay hold of the acid, and difcharge the volatile alkali.

A volatile alkali will decompound any neutal falt which has not a fixed alkali for its bafis; that is, all fuch as confift of an acid combined with an abforbent earth or a metallic fubftance. By joining with the acids in which they are diffolved, it difengages the earths or metallic fubftances, takes their place, and, in conjunction with their acids, forms ammoniac falts.

Hence it might be concluded, that, of all fubftances, next to the phlogifton and the fixed alkalis, volatile alkalis have the greateft affinity with acids in general. Yet there is fome difficulty in this matter: for abforbent earths and feveral metallic fubftances are alfo capable of decompounding ammoniacal falts, difcharging their volatile alkali, and forming new compounds by uniting with their acids. This might induce us to think that thefe fubftances have nearly the fame affinity with acids.

But it is proper to obferve, that a volatile alkali decompounds fuch neutral falts as have for their bafis either an abforbent earth or a metallic fubftance, without the aid of fire; whereas abforbent earths or metallic fubftances will not decompound an ammoniacal falt, unlefs they be affifted by a certain degree of heat.

Now, as all thefe matters are extremely fixed, at leaft in comparifon with a volatile alkali, they have the advantage of being able to refift the force of fire, and fo of acting in conjunction therewith; and fire greatly promotes the natural action of fubftances upon one another: whereas the volatile alkali in the ammoniacal falt, being unable to abide the force of fire, is compelled to defert its acid; and that fo much the more quickly, as its affinity therewith is confiderably weakened by the prefence of an earthy or metallic fubftance, both of which have a great affinity with acids.

Thefe confiderations oblige us to conclude, that volatile alkalis have a fomewhat greater affinity, than abforbent earths and metallic fubftances, with acids.

Ammoniacal falts projected upon nitre in fufion make it detonate; and the nitrous fal ammoniac detonates by itfelf, without the addition of any inflammable matter. This fingular effect evidently demonftrates the exiftence of an oily matter in volatile alkalis; for it is certain that nitre will never deflagrate without the concurrence and even the immediate contact of fome combuftible matter.

This oily fubftance is often found combined with volatile alkalis in fuch a large proportion as to difguife it in fome meafure, and render it exceeding foul. The falt may be freed from its fuperfluous oil by repeated fublimations;

tions; and particularly by fubliming it from abforbent earths, which readily drink up oils. This is called the *rectification* of a volatile alkali. The falt, which before was of a yellowifh or dirty colour, by being thus rectified, becomes very white, and acquires an odour more pungent and lefs fetid than it had at firft, that is, when obtained by one fingle diftillation from a putrid fubftance.

It is proper to obferve, that the rectification of a volatile alkali muft not be carried too far, or repeated too often; for by that means it may be entirely decompofed at length; and particularly if an abforbent earth, and efpecially chalk, be employed for that purpofe, the falt may be converted into an oil, an earth, and water.

Volatile alkalis act upon feveral metallic fubftances, and particularly on copper; of which they make a moft beautiful blue folution. On this property depends a pretty fingular effect, which happens fometimes when we attempt by means of a volatile alkali to feparate copper from an acid with which it is combined. Inftead of feeing the liquor grow turbid, and the metal fall, both which generally happen when any alkali whatever is mixed with a metallic folution, we are furprifed to obferve the folution of copper, upon adding a volatile alkali, retain its limpidity, and let fall no precipitate; or at leaft if the liquor does grow turbid, it remains fo but for a moment, and inftantly recovers its tranfparency. This is occafioned by adding fuch a quantity of volatile alkali as is more than fufficient fully to faturate the acid of the folution, and confiderable enough to diffolve all the copper as faft as it is feparated from the acid. On this occafion the liquor requires a deeper blue than it had before; which arifes from the property which volatile alkalis have of giving this metal, when combined with them, a fuller blue than any other folvent can: Hence we have a touchftone to difcover copper where-ever it is; for, let the quantity of this metal, combined with other metals, be ever fo fmall, a volatile alkali never fails to difcover it, by making it appear of a blue colour.

Though a volatile alkali be conftantly the refult of putrefaction, yet it muft not therefore be imagined, that none can be produced by any other means; on the contrary, moft of thofe which contain the ingredients neceffary to form it, yield no inconfiderable quantity thereof in diftillation. Tartar, for example, which by being burnt in an open fire is converted, as was fhewn, into a fixed alkali, yields a volatile alkali when it is decompofed in clofe veffels; that is, when it is diftilled: Becaufe, in this latter cafe, the oily part is not diffipated or burnt, as it is by calcination in a naked fire, but has time to unite with fome of the earth and acid of the mixt, in fuch a manner as to form a true volatile alkali.

To prove that on this occafion, as well as on all others, where unputrefied bodies yield a volatile alkali, this falt is the product of the fire, we need only obferve, that in thefe diftillations it never rifes till after fome part of the phlegm of the acid, and even of the thick oil of the mixt, is come over; which never is the cafe when it is formed before-hand in the body which is the fubject of the operation, as it is in thofe which have undergone putrefaction: For this falt, being much lighter and more volatile than thofe other fubftances, rifes of courfe before them in diftillation.

A General View of Chemical Decompofition.

Though we have confidered all the fubftances which enter into the compofition of vegetables, animals, and minerals, whether as primary or as fecondary principles, it will not be improper to fhew in what order we obtain thefe principles from the feveral mixts; and efpecially from vegetables and animals, becaufe they are much more complicated than minerals. This is called *analyfing* a compound.

The method moft commonly taken to decompofe bodies is by applying to them fucceffive degrees of heat, from the gentleft to the moft violent, in appropriated veffels, fo contrived as to collect what exhales from them. By this means the principles are gradually feparated from each other; the moft volatile rife firft, and the reft follow in order, as they come to be acted on by the proper degree of heat: And this is called *diftillation.*

But it being obferved that fire, applied to the decompofition of bodies, moft commonly alters their fecondary principles very fenfibly, by combining them in a different manner with each other, or even partly decompofing them, and reducing them to their primitive principles; other means have been ufed to feparate thofe principles without the help of fire.

With this view the mixts to be decompofed are forcibly compreffed, in order to fqueeze out of them all fuch parts of their fubftance as they will by this means part with; or elfe thofe mixts are for a long time triturated, either along with water, which carries off all their faline and faponaceous contents; or with folvents, fuch as ardent fpirits, capable of taking up every thing in them that is of an oily or refinous nature.

We fhall here give a fuccinct account of the effects of thefe different methods, as applied to the principal fubftances among vegetables and animals, and likewife to fome minerals.

The Analysis *of* Vegetable Substances.

A vaft many vegetable fubftances, fuch as kernels and feeds, yield by ftrong compreffion great quantities of mild, fat, unctuous oils, which are not foluble in ardent fpirits: Thefe are what we called *expreffed oils*. They are alfo fometimes called *fat oils*, on account of their unctuoufnefs, in which they exceed all other forts of oil. As thefe oils are obtained without the aid of fire, it is certain that they exifted in the mixt juft as we fee them, and that they are not in the leaft altered; which could not have been the cafe had they been obtained by diftillation: For that never produces any oils but fuch as are acrid and foluble in fpirit of wine.

Some vegetable matters, fuch as the rind of citrons, lemons, oranges, &c. alfo yield, only by being fqueezed between the fingers, a great deal of oil. This fpirts out in fine fmall jets, which being received upon any polifhed furface, fuch as a looking-glafs, run together, and form a liquor that is a real oil.

But

But it must be carefully noted, that this sort of oil, though obtained by expression only, is nevertheless very different from the oils mentioned before to which the title of *expressed oils* peculiarly belongs: For this is far lighter and thinner; moreover, it retains the perfect odour of the fruit which yields it, and is soluble in spirit of wine; in a word, it is a true essential oil, but abounds so in the fruits which produce it, and is lodged therein in such a manner, occupying a vast number of little cells provided in the peel for its reception, that a very slight pressure discharges it; which is not the case with many vegetables that contain an essential oil.

Succulent and green plants yield by compression a great deal of liquor or juice, which consists of most of the phlegm of the salts, and a small portion of the oil and earth of the plant. These juices, being set in a cool place for some time, deposit saline crystals, which are a combination of the acid of the plant with part of its oil and earth, wherein the acid is always predominant. These salts, as is evident from the description here given, bear a great resemblance to the tartar of wine treated of above. They are called *essential salts*; so that tartar might likewise be called the *essential salt of wine*.

Dried plants, and such as are of a ligneous, or acid nature, require to be long triturated with water, before they will yield their essential salts. Trituration with water is an excellent way to get out of them all their saline and saponaceous contents.

A vegetable matter that is very oily yields its essential salt with much difficulty, if at all; because the excessive quantity of oil entangles the salt so that it cannot extricate itself or shoot into crystals. Mr Gerike, in his *Princples of Chemistry*, says, That if part of the oil of a plant be extracted by spirit of wine, its essential salt may be afterwards obtained with more ease and in greater quantity.

Essential salts are among those substances which cannot be extracted from mixts by distillation; for the first impression of fire decomposes them.

Though the acid which predominates in the essential salts of plants be most commonly analogous to the vegetable acid, properly so called, that is, to the acid of vinegar and tartar, which is probably no other than the vitriolic acid disguised; yet it sometimes differs therefrom, and somewhat resembles the nitrous or the marine acid. This depends on the places where the plants grow which produce these salts: If they be submarine plants, their acid is a-kin to the acid of sea-salt; if, on the contrary, they grow upon walls, or in nitrous grounds, their acid is like that of nitre. Sometimes one and the same plant contains salts analogous to all the three mineral acids; which shews that the vegetable acids are no other than the mineral acids variously changed by circulating through plants.

Liquors containing the essential salts of plants being evaporated by a gentle heat to the consistence of honey, or even further, are called *extracts*. Hence it is plain, that an extract is nothing but the essential salt of a plant, combined with some particles of its oil and earth, that remained suspended in the liquor, and are now incorporated by evaporation.

Extracts of plants are also prepared by boiling them long in water, and then evaporating some part of it. But these extracts are of inferior virtue; because the fire dissipates many of the oily and saline parts.

EMULSIONS.

Substances which abound much in oil, being bruised and triturated with water for some time, afford a liquor of an opaque dead-white colour like milk. This liquor consists of such juices as the water is capable of dissolving, together with a portion of the oil, which being naturally indissoluble in water, is only divided and dispersed in the liquor, the limpidity whereof is by that means destroyed. This sort of oily liquor, in which the oil is only divided, not dissolved, is called an *emulsion*. The oily particles in emulsions spontaneously separate from the water, when left at rest, and, uniting into geater masses, rise, on account of their lightness, to the surface of the liquor, which by that means recovers a degree of transparency.

If vegetables, abounding in essential oils and resins, be digested in spirit of wine, the menstruum takes up these oily matters as being capable of dissolving them; and they may afterwards be easily separated from it by the affusion of water. The water, with which spirit of wine has a greater affinity than with oily matters, separates them by this means from their solvent, agreeable to the common laws of affinities.

Without the help of fire scarce any thing, besides the substances already mentioned, can be obtained from a plant: But by the means of distillation we are enabled to analyse them more completely. In prosecuting this method of extracting from a plant the several principles of which it consists, the following order is to be observed.

A plant being exposed to a very gentle heat, in a distilling vessel set in the *balneum mariæ*, yields a water which retains the perfect smell thereof. Some chemists, and particularly the illustrious Boerhaave, have called this liquor the *spiritus rector*. The nature of this odoriferous part of plants is not yet thoroughly known; because it is so very volatile, that it is difficult to subject it to the experiments necessary for discovering all its properties.

If instead of distilling the plant in the *balneum mariæ*, it be distilled over a naked fire, with the precaution of putting a certain quantity of water into the distilling vessel along with it, to prevent its suffering a greater heat than that of boiling water, all the essential oil contained in that plant will rise together with that water, and with the same degree of heat.

On this occasion it must be observed, that no essential oil can be obtained from a plant after the *spiritus rector* hath been drawn off; which gives ground to think that the volatility of these oils is owing to that spirit.

The heat of boiling water is also sufficient to separate from vegetable matters the fat oils which they contain: That, however, is to be done by the way of decoction only,

only, and not by diſtillation; becauſe, though theſe oils will ſwim on water, yet they will not riſe in vapours without a greater degree of heat,

When the eſſential oil is come over, if the plant be expoſed to a naked fire, without the addition of water, and the heat be increaſed a little, a phlegm will riſe that gradually grows acid; after which, if the heat be increaſed as occaſion requires, there will come over a thicker and heavier oil; from ſome a volatile alkali; and laſt of all, a very thick, black, empyreumatic oil.

When nothing more riſes with the ſtrongeſt degree of heat, there remains of the plant a mere coal only, called the *caput mortuum*, or *terra damnata*. This coal when burnt falls into aſhes, which being lixiviated with water give a fixed alkali.

It is obſervable, that in the diſtillation of plants which yield an acid and a volatile alkali, theſe two ſalts are often found quite diſtinct and ſeparate in the ſame receiver; which ſeems very extraordinary, conſidering that they are naturally diſpoſed to unite, and have a great affinity with one another. The reaſon of this phenomenon is, that they are both combined with much oil, which embarraſſes them ſo that they cannot unite to form a neutral ſalt, as they would not fail to do were it not for that impediment.

All vegetables, except ſuch as yield a great deal of volatile alkali, being burnt in an open fire, and ſo as to flame, leave in their aſhes a large quantity of an acrid, cauſtic, fixed alkali. But if care be taken to ſmother them, ſo as to prevent their flaming while they burn, by covering them with ſomething that may continually beat down again what exhales, the ſalt obtained from their aſhes will be much leſs acrid and cauſtic; the cauſe whereof is, that ſome part of the acid and oil of the plant being detained in the burning, and ſtopped from being diſſipated by the fire, combines with its alkali. Theſe ſalts cryſtallize, and being much milder than the common fixed alkalis, may be uſed in medicine, and taken internally. They are called *Tachenius*'s *ſalts*, becauſe invented by that chemiſt.

Marine plants yield a fixed alkali analogous to that of ſea-ſalt. As for all other plants or vegetable ſubſtances, the fixed alkalis obtained from them, if rightly prepared and thoroughly calcined, are all perfectly alike, and of the ſame nature.

The laſt obſervation we have to make on the production of a fixed alkali is, that if the plant you intend to work upon be ſteeped or boiled in water before you burn it, a much ſmaller quantity of ſalt will be obtained from it; nay, it will yield none at all, if repeated boilings have robbed it entirely of thoſe ſaline particles which muſt neceſſarily concur with its earth to form a fixed alkali.

The Analysis *of* Animal Substances.

Succulent animal ſubſtances, ſuch as new-killed fleſh, yield by expreſſion a juice or liquid, which is no other than the phlegm, replete with all the principles of the animal body, except the earth, of which it contains but little. The hard or dry parts, ſuch as the horns, bones, *&c.* yield a ſimilar juice, by boiling them in water. Theſe juices become thick, like a glue or jelly, when their watery parts are evaporated; and in this ſtate they are true extracts of animal matters These juices afford no cryſtals of eſſential ſalt, like thoſe obtained from vegetables, and ſhew no ſign either of an acid or an alkali.

Great part of the oil which is in the fleſh of animals may be eaſily ſeparated without the help of fire; for it lies in a manner by itſelf: It is commonly in a concrete form, and is called *fat*. This oil ſomewhat reſembles the fat oils of vegetables; for like them it is mild, unctuous, indiſſoluble in ſpirit of wine, and is ſubtilized and attenuated by the action of fire. But there is not in animals, as in vegetables, any light eſſential oil, which riſes with the heat of boiling water; ſo that, properly ſpeaking, animals contain but one ſort of oil.

Few animal ſubſtances yield a perceptible acid. Ants and bees are almoſt the only ones from which any can be obtained; and indeed the quantity which they yield is very ſmall, as the acid itſelf is extremely weak.

The reaſon thereof is, that as animals do not draw their nouriſhment immediately from the earth, but feed wholly either on vegetables or on the fleſh of other animals, the mineral acids, which have already undergone a great change by the union contracted between them and the oily matters of the vegetable kingdom, enter into a cloſer union and combination with theſe oily parts while they are paſſing through the organs and ſtrainers of animals; whereby their properties are deſtroyed, or at leaſt ſo impaired that they are no longer ſenſible.

Animal matters yield in diſtillation, firſt, a phlegm, and then, on increaſing the fire, a pretty clear oil, which gradually becomes thicker, blacker, more fetid, and empyreumatic. It is accompanied with a great deal of volatile alkali; and if the fire be raiſed and kept up till nothing more comes over, there will remain in the diſtilling veſſel a coal like that of vegetables; except that when it is reduced to aſhes, no fixed alkali, or at leaſt very little, can be obtained from them, as from the aſhes of vegetables. This ariſes from hence that, as we ſaid before, the ſaline principle in animals being more intimately united with the oil than it is in plants, and being conſequently more attenuated and ſubtilized, is too volatile to enter into the combination of a fixed alkali; on the contrary, it is more diſpoſed to join in forming a volatile alkali, which on this occaſion does not riſe till after the oil, and therefore muſt certainly be the production of the fire.

The chyle, and the milk of animals which feed on plants, ſtill retain ſome likeneſs to vegetables; becauſe the principles of which theſe liquors are compoſed have not gone through all the changes which they muſt ſuffer before they enter into the animal combination.

Urine and ſweat are excrementitious aqueous liquors, loaded chiefly with the ſaline particles which are of no ſervice towards the nouriſhment of the animal, but paſs through its ſtrainers without receiving any alteration; ſuch as the neutral ſalts which have a fixed alkali for their baſis, and particularly the ſea-ſalt which happens to be in the food of animals, whether it exiſt therein naturally, as it does in ſome plants, or whether the animals eat it to pleaſe their palates.

The

The saliva, the pancreatic juice, and especially the bile, are saponaceous liquors; that is, they consist of saline and oily particles combined together; so that being themselves dissolved in an aqueous liquor, they are capable of dissolving likewise the oily parts, and of rendering them miscible with water.

Lastly, The blood being the receptacle of all these liquors, partakes of the nature of each, more or less in proportion to the quantity thereof which it contains.

The Analysis *of* Mineral Substances.

Minerals differ greatly from vegetables, and from animals; they are not near so complex as those organized bodies, and their principles are much more simple; whence it follows, that these principles are much more closely connected, and that they cannot be separated without the help of fire; which not having on their parts the same action and the same power as on organized bodies, hath not the same ill effect on them; we mean the effect of changing their principles, or even destroying them entirely.

We do not here speak of pure, vitrifiable, or refractory earths; of mere metals and semi-metals; of pure acids; or even of their simplest combinations, such as sulphur, vitriol, alum, sea salt: Of all these we have said enough.

We are now to treat of bodies that are more complex, and therefore more susceptible of decomposition. These bodies are compound masses or combinations of those above-mentioned; that is, metallic substances as they are found in the bowels of the earth, united with several sorts of sand, stones, earths, semi-metals, sulphur, *&c.* When the metallic matter is combined with other matters in such a proportion to the rest that it may be separated from them with advantage and profit, these compounds are called *ores*: when the case is otherwise, they are called *pyrites*, and *marcasites*; especially if sulphur or arsenic be predominant therein, which often happens.

In order to analyse an ore, and get out of it the metal it contains, the first step is to free it from a great deal of earth and stones which commonly adhere to it very slightly and superficially. This is effected by pounding the ore, and then washing it in water; to the bottom of which the metalline parts presently sink, as being the heaviest, while the small particles of earth and stone remain suspended some time longer.

Thus the metallic part is left combined with such matters only as are most intimately complicated with it. These substances are most commonly sulphur and arsenic. Now, as they are much more volatile than other mineral matters, they may be dissipated in vapours, or the sulphur may be consumed, by exposing the ore which contains them to a proper degree of heat. If the sulphur and arsenic be desired by themselves, the fumes thereof may be catched and collected in proper vessels and places. This operation is called *roasting* in ore.

The metal thus depurated is now fit to be exposed to a greater force of fire, capable of melting it.

On this occasion the semi-metals and the imperfect metals require the addition of some matter abounding in phlogiston, particularly charcoal-dust; because these metallic substances lose their phlogiston by the action of the fire, or of the fluxes joined with them, and therefore without this precaution would never acquire either the splendor or the ductility of a metal. By this means the metallic substance is more accurately separated from the earthy and stony parts, of which some portion always remains combined therewith till it is brought to fusion. For, as we observed before, a metallic glass or calx only will contract an union with such matters; a metal possessed of its phlogiston and metalline form being utterly incapable thereof.

We took notice of the cause of this separation above, where we shewed that a metal possessed of its phlogiston and metalline form will not remain intimately united with any calcined or vitrified matter, not even with its own calx or glass.

The metal therefore on this occasion gathers into a mass, and lies at the bottom of the vessel, as being most ponderous; while the heterogeneous matters float upon it in the form of a glass, or a semi-vitrification. These floating matters take the name of *scoriæ*, and the metalline substance at bottom is called the *regulus*.

It frequently happens, that the metalline regulus thus precipitated, is itself a compound of several metals mixed together, which are afterwards to be separated.

It is proper to observe, before we quit this subject, that the rules here laid down for analysing ores are not absolutely general: For example, it is often adviseable to roast the ore before you wash it; for by that means some ores are opened, attenuated, and made very friable, which would cost much trouble and expence, on account of their excessive hardness, if you should attempt to pound them without a previous torrefaction.

It is also frequently necessary to separate the ore from part only of its stone; sometimes to leave the whole; and sometimes to add more to it, before you smelt it. This depends on the quality of the stone, which always helps to promote fusion when it is in its own nature fusible and vitrifiable: It is then called the *fluor* of the ore.

We shall now give a succinct account of the principal ores and mineral bodies, contenting ourselves with just pointing out the particulars of which they severally consist.

Of the Pyrites.

The Yellow Pyrites.

The yellow pyrites is a mineral consisting of sulphur, iron, an unmetallic earth, and frequently a little copper: The sulphur, which is the only one of these principles that is volatile, may be separated from the rest by sublimation: It usually makes a fourth, and sometimes a third, of the whole weight of these pyrites. The other principles are separated from one another by fusion and reduction with the phlogiston, which, by metallizing the ferruginous and cupreous earths, parts them from the unmetallic earth: for this earth vitrifies, and cannot afterwards continue united with metallic matters possessed of their metalline form.

There is yet another way of decomposing the yellow pyrites, which is to let it lie till it effloresces, or begins

to

to ſhoot into flowers; which is nothing but a ſort of ſlow accenſion of the ſulphur it contains. The ſulphur being by this means decompoſed, its acid unites with the ferruginous and cupreous parts of the pyrites, and therewith forms green and blue vitriols; which may be extracted by ſteeping in water the pyrites which has effloreſced or been burnt, and then evaporating the lixivium to a pellicle; for by this means the vitriol will ſhoot into cryſtals.

Sometimes the pyrites contains alſo an earth of the ſame nature with that of alum: A pyrites of this ſort, after flowering, yields alum as well as vitriol.

The White Pyrites.

The white pyrites contains much arſenic, a ferruginous earth, and an unmetallic earth. The arſenic being a volatile principle, may be ſeparated by ſublimation or diſtillation from the reſt, which are fixed; and theſe again may be disjoined from each other by fuſion and reduction, as was ſaid in relation to the yellow pyrites.

The Copper Pyrites.

The copper pyrites contains ſulphur, copper, and an unmetallic earth. A great deal thereof likewiſe holds arſenic, and its colour approaches more or leſs to orange, yellow, or white, according to the quantity of arſenic in it. It may be decompoſed by the ſame means as the yellow and white pyrites.

Of Ores.

Of Gold Ores.

Gold being conſtantly found in its metalline form, and never combined with ſulphur and arſenic, its ores are not, properly ſpeaking, ores; becauſe the metal contained in them is not mineralized. The gold is only lodged between particles of ſtone, earth, or ſand, from which it is eaſily ſeparated by lotion, and by amalgamation with quick-ſilver. The gold thus found is ſeldom pure, but is frequently alloyed with more or leſs ſilver, from which it is to be ſeparated by quartation.

It is alſo very common to find gold in moſt ores of other metals or ſemi-metals, and even in the pyrites; but the quantity contained therein is generally ſo ſmall, that it would not pay the coſt of extracting it. However, if any ſhould incline to attempt it, merely out of curioſity, it would be neceſſary to begin with treating theſe ores in the manner proper for ſeparating their metalline part; then to cupel the metalline regulus ſo obtained; and laſtly, to refine it by quartation.

Of Silver Ores.

It is no rare thing to find ſilver, as well as gold, in its metalline form, only lodged in ſundry earths and ſtony matters, from which it may be ſeparated in the ſame manner as gold. But the greateſt quantities of this metal are uſually dug out of the bowels of the earth in a truly mineral ſtate; that is, combined with different ſubſtances, and particularly with ſulphur and arſenic.

Several ſilver ores are diſtinguiſhed by peculiar characteriſtics, and are accordingly denoted by particular names. That which is called the *vitreous ſilver ore*, is ſcarce any thing elſe but a combination of ſilver and ſulphur. Another is known by the name of the *horny ſilver ore*, becauſe when in thin plates it is ſemi-tranſparent: In this ore the ſilver is mineralized by ſulphur and a little arſenic. The *red ſilver ore* is of the colour which its name imports, ſometimes more, ſometimes leſs vivid; and is chiefly compoſed of ſilver, arſenic, and ſulphur: It alſo contains a little iron.

Theſe three ores are very rich in ſilver: the firſt contains nearly three-fourths of its weight, and the others about two-thirds of theirs.

There is a fourth, called the *white ſilver ore*, which though it be heavier, is not ſo rich in ſilver, becauſe it contains much copper. Many other ores contain ſilver, yet are not, properly ſpeaking, ſilver ores; becauſe a much greater quantity of other metals than of ſilver is found in them.

When a ſilver ore is to be decompoſed, in order to have the ſilver pure, or when ſilver is to be extracted out of any ore that contains it, the firſt thing to be done is to roaſt the ore in order to clear it of the volatile minerals: and as ſilver cannot be had pure without the operation of the cupel, which requires more or leſs lead to be joined with it, it is uſual to mix with the torrified ſiler ore a quantity of lead proportioned to that of the heterogeneous matters combined with the ſilver, and to melt the whole together Part of the added lead vitrifies during the fuſion, and at the ſame time converts ſome of the heterogeneous matter alſo into glaſs, with which it forms a ſcoria that riſes to the ſurface of the matter. The other part of the lead, with which the ſilver is mixed, falls to the bottom in the form of a regulus, which muſt be cupelled in order to have the ſilver pure.

Of Copper Ores.

Copper is much ſeldomer found in a metalline form, than gold or ſilver; it is commonly in a mineral ſtate: it is mineralized by ſulphur and arſenic: almoſt all its ores contain alſo more or leſs iron; ſometimes a little ſilver or even gold, together with unmetallic earths and ſtones, as all ores do.

Moſt copper ores are of a beautiful green or blue, or elſe in ſhades blended of theſe two colours. The minerals called mountain green, and mountain blue, are true copper ores; not in the form of hard ſtones, like other ores, but crumbly and friable like earth.

Nevertheleſs there are ſeveral copper ores of different colours, as aſh-coloured, whitiſh, and ſhaded with yellow or orange: which colours ariſe from the different proportions of arſenic, ſulphur, and iron, which theſe ores contain.

In order to decompoſe a copper ore, and to extract the copper it contains, it is firſt of all to be freed from as many of its earthy, ſtony, ſulphureous, and arſenical parts, as is poſſible, by roaſting and waſhing; then what remains is to be mixed with a flux compounded of a fixed alkali and ſome inflammable matter; a little ſea-ſalt is to be put over all, and the whole melted by a ſtrong fire. The ſalts facilitate the ſuſion and ſcorification of the

the unmetallic matters, and therewith form a flag, which being the lighteſt riſes to the ſurface. The metalline matters are collected below in the form of a ſhining regulus of copper; which however, is not uſually fine copper, but requires to be purified.

In order to ſeparate the copper from the unmetallic matters, it is abſolutely neceſſary to melt its ore along with the inflammable ſubſtances abounding in phlogiſton. For, as this metal is not poſſeſſed of its metalline form while it is in a mineral ſtate, as it is deſtitute of the true quantity of phlogiſton, and, though it were not, would loſe it by the action of the fire, it would come to paſs, that, if its ore were melted without the addition of any inflammable matter, the cupreous earth, or calx, would be ſcorified and confounded with the unmetallic matters; and as all metallic matters, except gold and ſilver, are ſubject to this inconvenience as well as copper, the addition of an inflammable ſubſtance, in fluxing all ores that contain them, is a general rule that ought conſtantly to be obſerved.

Of Iron Ores.

Iron is ſeldom found pure and malleable in the earth; yet it is much ſeldomer found in the mineral ſtate, properly ſo called, than any of the other metals: for moſt iron ores are ſcarce any thing more than a ferruginous earth mixed in different proportions with unmetallic earths and ſtones. Some of them, however, contain alſo volatile minerals, ſuch as ſulphur and arſenic; and therefore it is neceſſary to roaſt the iron ores, like all others, before you attempt to extract the metal out of them. That being done, they are to be ſmelted with a flux conſiſting of fuſible and inflammable matters, as the general rule directs.

Iron is the commoneſt of all metals; nay, it is ſo univerſally diffuſed through the earth, that it is difficult to find any ſtone, earth, or ſand, that does not contain ſome of it; and therefore none of theſe are uſually conſidered and treated as iron ores, except ſuch as contain a great deal of that metal, and melt eaſily. The hematites, emery, yellow pyrites, calamine, all contain a pretty conſiderably quantity of iron; but nobody attempts to extract it from them, becauſe they are very hard to melt.

Ferruginous earth being naturally of an orange colour, a ſtone or earth may be judged to contain iron, if either naturally or after roaſting it appears to have any ſhade of yellow or red.

The ſingular property which iron has of being attracted by the magnet, and of being the only body, excluſive of all others, that is ſo, likewiſe affords us an eaſy method of diſcovering the preſence of this metal among other matters, where it often exiſts in ſuch a ſmall quantity that it could not otherwiſe be found out. For this purpoſe the body in which iron is ſuſpected to lurk, muſt be pulveriſed and torrefied with ſome inflammable matter; and then the powder thus roaſted being touched with a magnet, or a magnetical bar, if it contains any particles of iron they will infallibly adhere to the magnet or bar.

Of Tin Ores.

Tin is never found in the earth pure and malleable, but always in a mineral ſtate, and always mineraliſed by arſenic. Tin ores are not ſulphureous; whence it comes that though tin be the lighteſt of all metals, its ores are nevertheleſs heavier than thoſe of other metals, as arſenic greatly exceeds ſulphur in gravity. Some tin ores contain alſo a little iron. The ores of tin are to be waſhed, roaſted, and ſmelted with a reducing flux, according to the general rules.

Of Lead Ores.

Lead, like tin, is never found but in a mineral ſtate. It is moſt commonly mineraliſed by ſulphur; yet there are ſome lead ores which alſo contain arſenic.

Lead ores, as well as all others, muſt be roaſted and ſmelted with a reducing flux: however, as it is difficult to free them from all their ſulphur by torrefaction only, the reducing flux employed in their fuſion may be made up with a quantity of iron filings, which being incapable of any union with lead, and having a much greater affinity than that metal with ſulphur, will on this occaſion be of great ſervice by interpoſing between them.

Of Quick-Silver Ores.

Running mercury is ſometimes found in certain earths, or grey friable ſtones; but moſt commonly in a mineral ſtate. It is always mineralized by ſulphur, and by ſulphur alone: ſo that cinabar is the only ore of quick-ſilver that we know of: and a very rich one it is, ſeeing it contains ſix or ſeven times as much mercury as ſulphur.

Roaſting can be of no uſe towards decompoſing the ore of mercury, and ſeparating its ſulphur; becauſe mercury being itſelf very volatile would be carried off by the fire together with the ſulphur. In order therefore to part the two ſubſtances of which cinabar conſiſts, recourſe muſt neceſſarily be had to ſome third body, which will unite with one of them, and by that means ſeparate it from the other. Now all the metals, except gold, having a greater affinity than mercury with ſulphur, ſuch a body is eaſily found: any metal but gold may be employed with ſucceſs in this decompoſition; but as iron hath a greater affinity with ſulphur than any of the reſt, and is, moreover, the only one that cannot unite with mercury, it muſt, on account of theſe two qualities, be preferred to all the reſt.

Fixed alkalis are alſo well qualified to abſorb the ſulphur of cinabar. Cinabar muſt be decompounded in cloſe veſſels, and by the way of diſtillation: otherwiſe the mercury, as ſoon as it ſeparates from the ſulphur, will be diſſipated in vapours and entirely loſt.

In this operation it is needleſs to add either flux or phlogiſton; becauſe the cinabar is decompoſed without melting, and the mercury, though in a mineral ſtate, contains, like gold and ſilver, all the phlogiſton requiſite to ſecure its metalline properties.

Of the Ores of Regulus of Antimony.

Regulus of antimony is always found in a mineral ſtate: it is mineraliſed by ſulphur: but ſometimes, tho' rarely, it is alſo combined with a little arſenic.

When the ore of regulus of antimony is to be decompoſed,

poſed, the firſt thing to be done, is to expoſe it to a degree of heat too weak to melt its earthy and ſtony parts, but ſtrong enough to fuſe its reguline together with its ſulphureous parts, which by this means are ſeparated from the earth, and united into one maſs, known by the name of Antimony.

It is plain, that this firſt operation, which is founded on the great fuſibility of antimony, produces, with regard to the ore of regulus of antimony, the ſame effect that waſhing hath on other ores: ſo that after this firſt fuſion nothing more is requiſite to the obtaining of a pure regulus of antimony, but to ſeparate it from its ſulphur by roaſting, and to melt it with ſome matter abounding in phlogiſton, in the ſame manner as other metallic matters are treated. The term calcination is generally uſed to expreſs this torrefaction of antimony, by means whereof the metallic earth of the regulus of antimony is ſeparated from its ſulphur.

As regulus of antimony hath, like mercury, much leſs affinity with ſulphur than the other metals have, it follows that antimony may be decompoſed by the ſame means as cinabar; but the regulus ſo obtained is adulterated with a portion of the additament made uſe of, which combines therewith.

Of the Ores of Biſmuth.

The ore of biſmuth conſiſts of the ſemi-metal mineraliſed by the arſenic, and of an unmetallic earth. It is very eaſy to decompoſe this ore, and to extract the biſmuth it contains: for this purpoſe it need only be expoſed to a moderate heat, whereby the arſenic will be diſſipated in vapours, and the biſmuth melted, which will then ſeparate from the unmetallic earth. This earth, at leaſt in ſeveral ores of biſmuth, poſſeſſes the property of tinging all vitrifiable matters with which it is melted of a beautiful blue colour.

To decompoſe the ore of biſmuth no flux or inflammable matter is uſed; becauſe this ſemi-metal is poſſeſſed, even in its mineral ſtate, of all the phlogiſton requiſite to maintain its metalline properties; and its great fuſibility makes it unneceſſary to melt the metallic earth contained in its ore.

Of the Ores of Zinc.

Zinc is not generally obtained from a particular ore of its own; but ſublimes during the fuſion of a mineral, or rather a confuſed maſs of minerals, that contains this ſemi-metal together with iron, copper, lead, ſulphur, arſenic, and, like all other ores, an unmetallic earth.

Neverthelefs there is a ſubſtance which may be conſidered as the proper ore of zinc, becauſe it contains a pretty large quantity of that ſemi-metal, a little iron, and an unmetallic earth. It is called calamine, or *lapis calaminaris:* but hitherto the art of procuring zinc directly from this mineral hath no where been practiſed. Calamine is commonly employed only to convert copper into braſs or a yellow metal, by cementing it therewith. Indeed till lately no eaſy or practicable method of obtaining pure zinc from calamine was publicly known; for that ſemi-metal being volatile and very inflammable, its ore cannot be fuſed like others. Mr Margraaf was the firſt who, by mixing powdered charcoal with calamine, in cloſe veſſels, obtained a perfect zinc from it, by the means of diſtillation or ſublimation.

Of Arſenical Minerals.

Arsenic, as well as ſulphur, is naturally combined with almoſt all ores, or minerals containing metallic ſubſtances. As it is very volatile, while the matters with which it is united are fixed, at leaſt in compariſon therewith, it is eaſily ſeparated by ſublimation.

The minerals that contain moſt arſenic are the white pyrites, orpiment, and cobalt. We have already conſidered the white pyrites: as to orpiment, it conſiſts of ſulphur and arſenic. Both theſe ſubſtances being very volatile, it is difficult to ſeparate them by ſublimation: yet, with proper management, and a due regulation of the fire, this ſeparation may be effected; becauſe ſulphur ſublimes a little more eaſily than arſenic. But it is more convenient, as well as more expeditious, to make uſe of ſome additament that hath a greater affinity with one of thoſe ſubſtances than with the other. Fixed alkalis and mercury, both of which have more affinity with ſulphur than with arſenic, may be very properly employed on this occaſion. Cobalt is a mineral compoſed of arſenic, an unmetallic earth, and frequently biſmuth: and as none of theſe are very volatile, except the arſenic, this may be eaſily ſeparated from the reſt by ſublimation. The unmetallic earth which remains has, like that of the ore of biſmuth, the property of giving a blue colour to any vitrifiable matters melted with it; whence it is conjectured, that cobalt and the ore of biſmuth have a great reſemblance, or are often blended with each other.

Beſides the minerals already recited, there is found in the bowels of the earth another ſpecies of compound body, of which we have already taken notice; but which is ſuppoſed, with ſome degree of probability, to belong as much to the vegetable as to the mineral kingdom: we mean the bitumens; which the beſt obſervations oblige us to conſider as vegetable oils, that by lying long in the earth have contracted an union with the mineral acids, and by that means acquired the thickneſs, conſiſtence, and other properties obſervable in them.

By diſtillation they yield an oil, and an acid not unlike a mineral acid. Mr Bourdelin has even demonſtrated, by a very artful and ingenious proceſs, that amber contains a manifeſt acid of ſea-ſalt.

Explanation of the Table of Affinities or elective Attractions.

We have already explained what is meant by affinities, and have laid down the principal laws to which the relations of different bodies are ſubject. The late Mr Geoffroy, being convinced of the advantages which all who cultivate chemiſtry would receive from having conſtantly before their eyes a ſtate of the beſt aſcertained relations between the chief agents in chemiſtry, was the firſt who undertook to reduce them into order, and unite them all in one point of view, by means of a table. This table will be of conſiderable uſe to ſuch as are beginning to ſtudy

A. Bell Sculp.

ſtudy chemiſtry, in helping them to form a juſt idea of the relations which different ſubſtances have with one another; and the practical chemiſt will thereby be enabled to account for what paſſes in ſeveral of his operations, otherwiſe difficult to be underſtood, as well as to judge what may be expected to reſult from mixtures of different compounds. Theſe reaſons have induced us to inſert it at the end of this elementary treatiſe, and to give a ſhort explanation of it here; eſpecially as it will ſerve at the ſame time for a recapitulation of the whole work, in which the ſeveral axioms of this table are diſperſed. See Plate LXV.

The upper line of Mr Geoffroy's table comprehends ſeveral ſubſtances uſed in chemiſtry. Under each of thoſe ſubſtances are ranged in diſtinct columns ſeveral matters compared with them, in the order of their relation to that firſt ſubſtance; ſo as that which is the neareſt to it is that which hath the greateſt affinity with it, or that which none of the ſubſtances ſtanding below it can ſeparate therefrom; but which, on the contrary, ſeparates them all when they are combined with it, and expels them in order to join itſelf therewith. The ſame is to be underſtood of that which occupies the ſecond place of affinity; that is, it has the ſame property with regard to all below it, yielding only to that which is above it: and ſo of all the reſt.

At the top of the firſt column ſtands the character which denotes an acid in general. Immediately under this ſtands the mark of a fixed alkali, being placed there as the ſubſtance which has the greateſt affinity with an acid. After the fixed alkali, appears the volatile alkali, whoſe affinity with acids yields only to the fixed alkali. Next come the abſorbent earths; and, laſt of all, metallic ſubſtances. Hence it follows, that when a fixed alkali is united with an acid, it cannot be ſeparated therefrom by any other ſubſtance; that a volatile alkali united with an acid cannot be ſeparated from it by any thing but a fixed alkali; that an abſorbent earth combined with an acid may be ſeparated from it either by a fixed or by a volatile alkali; and laſtly, that any metallic ſubſtance combined with an acid, may be ſeparated from it by a fixed alkali, a volatile alkali, or an abſorbent earth.

At the head of the ſecond column ſtands the character of the marine acid, which ſignifies that the affinities of this acid are the ſubject of the column. Immediately below it is placed the mark of tin. As this is a metalline ſubſtance, and as the firſt column places metalline ſubſtances in the loweſt degree of affinity with all acids, it is plain we muſt ſuppoſe fixed alkalis, volatile alkalis, and abſorbent earths, to be placed here in order after the marine acids, and before tin. Tin, then, is of all metalline ſubſtances that which has the greateſt affinity with the marine acid; and then follow regulus of antimony, copper, ſilver, mercury. Gold comes laſt of all; and there are no leſs than two vacant places above it. By this means it is in ſome ſort excluded from the rank of ſubſtances that have an affinity with the marine acid. The reaſon thereof is, that this acid alone is not capable of diſſolving gold and combining therewith, neceſſarily requiring for that purpoſe the aid of the nitrous acid, or at leaſt of the phlogiſton.

The third column exhibits the affinities of the nitrous acid, the character whereof ſtands at its head. Immediately below it is the ſign of iron, as the metal which has the greateſt affinity with this acid; and then follow other metals, each according to the degree of its relation, *viz.* copper, lead, mercury, and ſilver. In this column, as in the preceding one, we muſt ſuppoſe the ſubſtances, which in the firſt column ſtand above metallic ſubſtances, to be placed in their proper order before iron.

The fourth column is intended to repreſent the affinities of the vitriolic acid. The phlogiſton ſtands uppermoſt. Below it the fixed alkalis, volatile alkalis, and abſorbent earths, to ſhew that this is an exception to the firſt column. As to metalline ſubſtances, Mr Geoffroy has ſet down but three, being thoſe with which the vitriolic acid has the moſt perceptible affinity: theſe metals, placed in the order of their affinities, are iron, copper, and ſilver.

The fifth column ſhews the affinities of abſorbent earths. As theſe earths have no ſenſible affinity but with acids, this column contains only the characters of the acids ranked according to the degree of their ſtrength, or affinity with the earths, *viz.* the vitriolic, the nitrous, and the marine acids. Underneath this laſt might be placed the acid of vinegar, or the vegetable acid.

The ſixth column expreſſes the affinities of fixed alkalis with acids, which are the ſame with thoſe of abſorbent earths. Moreover, we find ſulphur placed here below all the acids; becauſe liver of ſulphur, which is a combination of ſulphur with a fixed alkali, is actually decompounded by any acid: for any acid precipitates the ſulphur and unites with the alkali.

Immediately over the ſulphur, or in the ſame ſquare with it, might be ſet a mark denoting the volatile ſulphureous ſpirit; becauſe, like ſulphur, it has leſs affinity than any other acid with fixed alkalis. Oils might alſo be ranked with ſulphur, becauſe they unite with fixed alkalis, and therewith form ſoaps which are decompounded by any acid whatever.

The ſeventh column points out the affinities of volatile alkalis, which are likewiſe the ſame as thoſe of abſorbent earths; and the vegetable acid might be placed here alſo under the marine acid.

The eighth column ſpecifies the affinities of metallic ſubſtances with acids. The affinities of the acids, which with reſpect to fixed alkalis, volatile alkalis, and abſorbent earths, ſucceed each other uniformly, do not appear in the ſame order here. The marine acid, inſtead of being placed below the vitriolic and nitrous acids, ſtands, on the contrary, at their head; becauſe, in fact, this acid ſeparates metalline ſubſtances from all the other acids with which they happen to be united, and, forcing theſe acids to quit poſſeſſion, intrudes into their place. Nevertheleſs, this is not a general rule; for ſeveral metalline ſubſtances muſt be excepted, particularly iron and copper.

The ninth column declares the affinities of ſulphur. Fixed alkalis, iron, copper, lead, ſilver, regulus of antimony, mercury, and gold, ſtand below it in the order of their affinities. With regard to gold, it muſt be obſerved, that it will not unite with pure ſulphur; it ſuffers

fers itſelf to be diſſolved only by the liver of ſulphur, which is known to be a compoſition of ſulphur and fixed alkali.

At the head of the tenth column appears mercury, and beneath it ſeveral metalline ſubſtances, in the order of their affinities with it. Thoſe metalline ſubſtances are gold, ſilver, lead, copper, zinc, and regulus of antimony.

The eleventh column ſhews that lead has a greater affinity with ſilver than with copper.

The twelfth, that copper has a greater affinity with mercury than with calamine.

The thirteenth, that ſilver has a greater affinity with lead than with copper.

The fourteenth contains the affinities of iron. Regulus of antimony ſtands immediately underneath it, as being the metallic ſubſtance which has the greateſt affinity with it. Silver, copper, and lead, are placed together in the next ſquare below, becauſe the degrees of affinity which thoſe metals have with iron are not exactly determined.

The ſame is to be ſaid of the fifteenth column: Regulus of antimony ſtands at its head; iron is immediately below it; and below the iron the ſame three metals occupy one ſquare as before.

Laſtly, The ſixteenth column indicates that water has a greater affinity with ſpirit of wine than with ſalts. By this general expreſſion muſt not be underſtood any ſaline ſubſtance whatever; but only the neutral ſalts, which ſpirit of wine frees from the water that kept them in ſolution. Fixed alkalis, on the contrary, as well as the mineral acids, have a greater affinity than ſpirit of wine with water; ſo that theſe ſaline ſubſtances, being well dephlegmated and mixed with ſpirit of wine, imbibe the water it contains and rectify it.

The Theory of Conſtructing the Veſſels moſt commonly uſed in Chemiſtry.

Chemists cannot perform the operations of their art without the help of a conſiderable number of veſſels, inſtruments, and furnaces, adapted to contain the bodies on which they intend to work, and to apply to them the ſeveral degrees of heat required by different proceſſes.

Veſſels intended for chemical operations ſhould be able to bear, without breaking, the ſudden application of great heat and great cold; be impenetrable to every thing, and unalterable by any ſolvent; unvitrifiable, and capable of enduring the moſt violent fire without melting: But hitherto no veſſels have been found with all theſe qualities united.

They are made of ſundry materials, namely, of metal, of glaſs, and of earth. Metalline veſſels, eſpecially thoſe made of iron or copper, are apt to be corroded by almoſt every ſaline, oily, or even aqueous ſubſtance. For this reaſon, in order to render the uſe of them a little more extenſive, they are tinned on the inſide. But, notwithſtanding this precaution, they are on many occaſions not to be truſted; and ſhould never be employed in any nice operations which require great accuracy; they are, moreover, incapable of reſiſting the force of fire.

Earthen veſſels are of ſeveral ſorts. Some, that are made of a refractory earth, are capable of being ſuddenly expoſed to a ſtrong fire without breaking, and even of ſuſtaining a great degree of heat for a conſiderable time: But they generally ſuffer the vapours of the matters which they contain, as well as vitrified metals, to paſs through them; eſpecially the glaſs of lead, which eaſily penetrates them, and runs through their pores, as through a a ſieve. There are others made of an earth, that, when well baked, looks as if it were half vitrified: Theſe being much leſs porous are capable of retaining the vapours of the matters which they contain, and even glaſs of lead in fuſion; which is one of the ſevereſt trials a veſſel can be put to: But then they are more brittle than the other ſort.

Good glaſs-veſſels ſhould conſtantly be employed in preference to all others, whenever they can poſſibly be uſed: And that not only becauſe they are no way injured by the moſt active ſolvents, nor ſuffer any part of what they contain to paſs through, but alſo becauſe their tranſparency allows the chemiſt to obſerve what paſſes within them; which is always both curious and uſeful. But it is pity, that veſſels of this ſort ſhould not be able to endure a fierce fire without melting.

Diſtillation, as hath been already ſaid, is an operation by which we ſeparate from a body, by the help of a gradual heat, the ſeveral principles of which it conſiſts.

There are three methods of diſtilling. The firſt is performed by applying the heat over the body whoſe principles are to be extracted. In this caſe, as the liquors when heated and converted into vapours conſtantly endeavour to fly from the centre of heat, they are forced to re-unite in the lower part of the veſſel that contains the matter in diſtillation, and ſo paſſing through the pores or holes of that veſſel, they fall into another cold veſſel applied underneath to receive them. This way of diſtilling is, on this account, called diſtilling *per deſcenſum*. It requires no other apparatus than two veſſels figured like ſegments of hollow ſpheres, whereof that which is pierced with little holes, and intended to contain the matter to be diſtilled, ought to be much leſs than the other which is to contain the fire, and cloſe its aperture exactly; the whole together being ſupported vertically upon a third veſſel, which is to ſerve the purpoſe of a recipient, admitting into its mouth the convex bottom of the veſſel containing the matter to be diſtilled, which muſt accurately fill it. This method of diſtilling is but little uſed.

The ſecond method of diſtilling is performed by applying the heat underneath the matter to be decompoſed. On this occaſion the liquors being heated, rarefied, and converted into vapours, riſe, and are condenſed in a veſſel contrived for that purpoſe, which we ſhall preſently deſcribe. This way of diſtilling is called diſtilling *per aſcenſum*, and is much uſed.

The veſſel in which the diſtillation *per aſcenſum* is performed, we call an alembic. Plate LXIV. fig. 1.

There are ſeveral ſorts thereof differing from one another both in the matter of which, and the manner in which, they are made.

Thoſe

Thoſe employed to draw the odoriferous waters and eſſential oils of plants are generally made of copper, and conſiſt of ſeveral pieces. The firſt, which is deſigned to contain the plant, is formed nearly like a hollow cone, the vertex whereof is drawn out in the ſhape of a hollow cylinder or tube: This part is named the cuburbit, Plate LXIV. fig. 1. A; and its tube the neck of the alembic B. To the upper end of this tube another veſſel is ſoldered: This is called the head C, and commonly has likewiſe the form of a cone, joined to the neck of the alembic by its baſe, round which on the inſide is hollowed a ſmall groove communicating with an orifice that opens at its moſt depending part. To this orifice is ſoldered a ſmall pipe in a direction ſloping downwards, which is called the noſe, ſpout, or beak D of the alembic.

As ſoon as the matters contained in the alembic grow hot, vapours begin to ariſe from them, and aſcending through the neck of the alembic into the head, are by the ſides thereof ſtopped and condenſed: From thence they trickle down in little ſtreams to the groove, which conveys them to the ſpout; and by that they paſs out of the alembic into a glaſs veſſel or receiver G with a long neck, the end of the ſpout being introduced into that neck and luted thereto.

To facilitate the refrigeration and condenſation of the vapours circulating in the head, all alembics of metal are moreover provided with another piece, which is a kind of large pan of the ſame metal, fitted and ſoldered round the head. This piece ſerves to keep cold water in, which inceſſantly cools the head, and therefore it is called the refrigeratory E. The water in the refrigeratory itſelf grows hot after ſome time, and muſt therefore be changed occaſionally; the heated water being firſt drawn off by means of a cock fixed near the bottom of the refrigeratory. All copper alembics ſhould be tinned on the inſide for the reaſons already given.

When ſaline ſpirits are to be diſtilled, alembics of metal muſt not be uſed; becauſe the ſaline vapours would corrode them. In this caſe recourſe muſt be had to alembics of glaſs. Theſe conſiſt of pieces only; namely, a cucurbit, whoſe ſuperior orifice is admitted into, and exactly luted with its head, which is the ſecond piece.

In general, as alembics require that the vapours of the matter to be diſtilled ſhould riſe to a conſiderable height, they ought to be uſed only when the moſt volatile principles are to be drawn from bodies: And the lighter and more volatile the ſubſtances to be ſeparated by diſtillation are, the taller muſt the alembic be; becauſe the moſt ponderous parts, being unable to riſe above a certain heighth, fall back again into the cucurbit as ſoon as they arrive there, leaving the lighter to mount alone, whoſe volatility qualifies them to aſcend into the head.

When a matter is to be diſtilled that requires a very tall alembic, and yet does not admit of a metalline veſſel, the end will be beſt anſwered by a glaſs veſſel of a round or oval ſhape, having a very long neck, with a ſmall head fitted to its extremity. Such a veſſel ſerves many purpoſes: It is ſometimes employed as a receiver, and at other times as a digeſting veſſel; on which laſt occaſion it goes under the name of a matraſs, fig. 3. When one of theſe provided with a head, (fig. 3. C), is applied to the purpoſe of diſtilling, it forms a ſort of alembic.

There are ſome alembics of glaſs, blown in ſuch a manner by the workmen, that the body and head form but one continued piece. As theſe alembics do not ſtand in need of having their ſeveral pieces luted together, they are very uſeful on ſome occaſions, when ſuch exceeding ſubtile vapours riſe as are capable of tranſpiring through lutes. The head muſt be open at the top, and provided with a ſhort tube, through which by means of a funnel with a long pipe, the matter to be diſtilled may be introduced into the cucurbit. This is to be exactly cloſed with a glaſs ſtopple, the ſurface whereof muſt be made to fit the inſide of the tube in every point, by rubbing thoſe two pieces well together with emery.

Another ſort of alembic hath alſo been invented, which may be uſed with advantage when cohobation is required; that is, when the liquor obtained by diſtillation is to be returned upon the matter in the cucurbit; and eſpecially when it is intended that this cohobation ſhall be repeated a great number of times. The veſſel we are ſpeaking of is conſtructed exactly in the ſame manner as that laſt deſcribed; except that its beak, inſtead of being in a ſtreight line as in the other alembics, forms a circular arch, and re-enters the cavity of the cucurbit, in order to convey back again the liquor collected in the head. This inſtrument hath commonly two beaks oppoſite to each other, both turned in this manner, and is called a *pelican:* It ſaves the artiſt the trouble of frequently unluting and reluting his veſſels, as well as the loſs of a great many vapours.

There are certain ſubſtances which in diſtillation afford matters in a concrete form, or riſe wholly in the form of a very light powder, called *flowers*. When ſuch ſubſtances are to be diſtilled, the cucurbit which contains them is covered with a head without a noſe, which is named a *blind-head*.

When the flowers riſe in great quantities and very high, a number of heads is employed to collect them; or rather a number of a kind of pots, conſiſting of a body only without any bottom, which fitting one into the other form a canal, that may be lengthened or ſhortened at pleaſure, according as the flowers to be ſublimed are more or leſs volatile. The laſt of the heads, which terminates the canal, is quite cloſe at one end, and makes a true blind-head. Theſe veſſels are called *aludels*: they are uſually of earthen or ſtone ware.

All the veſſels above mentioned are fit only for diſtilling ſuch light volatile matters as can be eaſily raiſed and brought over; ſuch as phlegm, eſſential oils, fragrant waters, acid oily ſpirits, volatile alkalis, *&c.* But when the point is to procure, by diſtillation, principles that are much leſs volatile, and incapable of riſing high, ſuch as the thick fetid oils, the vitriolic, the nitrous, and the marine acids, *&c.* we are under a neceſſity of having recourſe to other veſſels, and another manner of diſtilling.

It is eaſy to imagine, that ſuch a veſſel muſt be much lower than the alembic. It is indeed no more than a hollow globe, whoſe upper part degenerates into a neck or

or tube, that is bent into a horizontal poſition; for which reaſon this inſtrument is called a *retort:* It is always of one ſingle piece.

The matter to be diſtilled is introduced into the body of the retort by means of a ladle with a long tubular ſhank. Then it is ſet in a furnace built purpoſely for this uſe, and ſo that the neck of the retort coming out of the furnace may, like the the noſe of the alembic, ſtand in a ſloping poſition, to facilitate the egreſs of the liquors, which by its means are conveyed to a receiver, into which it is introduced, and with which it is luted. This way of diſtilling, in which the vapours ſeem rather to be driven out of the veſſel horizontally and laterally, than raiſed up and ſublimed, is for that reaſon called diſtillation *per latus.*

Retorts are, of all the inſtruments of diſtillation, thoſe that muſt ſuſtain the greateſt heat, and reſiſt the ſtrongeſt ſolvents; and therefore they muſt not be made of metal. Some, however, which are made of iron may do well enough on certain occaſions: The reſt are either of glaſs or earth. Thoſe of glaſs, for the reaſons above given, are preferable to the other ſort, in all caſes where they are not to be expoſed to ſuch a force of fire as may melt them. The beſt glaſs, that which ſtands both heat and ſolvents beſt, is that in which there are feweſt alkaline ſalts: Of this ſort is the green German glaſs: The beautiful white cryſtal glaſs is far from being equally ſerviceable.

Retorts, as well as alembics, may be of different forms. For example, ſome matters are apt to ſwell and riſe over the neck of the retort in ſubſtance without ſuffering any decompoſition; when ſuch matters are to be diſtilled in a retort, it is proper that the body of the veſſel, inſtead of being globular, be drawn out into the form of a pear, ſo as nearly to reſemble that of a cucurbit. In a retort of this kind, the diſtance between the bottom and the neck being much greater than in thoſe whoſe bodies are ſpherical, the matters contained have much more room for expanſion; ſo that the inconvenience here mentioned is thereby prevented. Retorts of this form are called Engliſh retorts: as they hold the middle place between alembics and common retorts, they may be uſed to diſtill ſuch matters as have a mean degree of volatility between the greateſt and the leaſt.

It is moreover proper to have in a laboratory ſundry retorts with necks of different diameters. Wide necks will be found the fitteſt for conveying thick matters, and ſuch as readily become fixed; for inſtance, ſome very thick fetid oils, butter of antimony, *&c.* for as theſe matters acquire a conſiſtence as ſoon as they are out of the reach of a certain degree of heat, they would ſoon choak up a narrow neck, and by ſtopping the vapours, which riſe at the ſame time from the retort, might occaſion the burſting of the veſſels.

Some retorts are alſo made with an opening on their upper ſide, like that of tubulated glaſs alembics, which is to be cloſed in the ſame manner with a glaſs ſtopple. Theſe retorts are alſo called *tubulated retorts*, and ought always to be uſed whenever it is neceſſary to introduce freſh matter into the retort during the operation; ſeeing it may be done by means of this invention, without unluting and reluting the veſſels; which ought always to be avoided as much as poſſible

One of the things that moſt perplexes the chemiſts is, the prodigious elaſticity of many different vapours, which are frequently diſcharged with impetuoſity during the diſtillation, and are even capable of burſting the veſſels with exploſion, and with danger to the artiſt. On ſuch occaſions it is abſolutely neceſſary to give theſe vapours vent, as we ſhall direct in its proper place: But as that can never be done without loſing a great many of them; as ſome of them in particular are ſo elaſtic, that ſcarce any at all would remain in the veſſel; for inſtance, thoſe of the ſpirit of nitre, and eſpecially thoſe of the ſmoking ſpirit of ſalt; the practice is to make uſe of very large receivers, of about eighteen or twenty inches diameter, that the vapours may have ſufficient room to circulate in, and, by applying to the wide ſurface preſented them by the extenſive inſide of ſuch a large veſſel, may be condenſed into drops. Theſe huge receivers are commonly in the form of hollow globes, and are called *ballons.*

To give theſe vapours ſtill more room, ballons have been contrived with two open gullets in each, diametrically oppoſite to one another; whereof one admits the neck of the retort, and the other is received by one of the gullets of a ſecond ballon of the ſame form, which is joined in like manner to a third, and ſo on. By this artifice the ſpace may be enlarged at pleaſure. Theſe ballons with two necks are called *adopters.*

Operations on bodies that are abſolutely fixed, as metals, ſtones, ſand, *&c.* require only ſuch veſſels as are capable of containing thoſe bodies and reſiſting the force of fire. Theſe veſſels are little hollow pots, of different dimenſions, which are called crucibles. Crucibles can hardly be made of any thing but earth; they ought to have a cover of the ſame material fitted to ſhut them cloſe. The beſt earth we know is that whereof thoſe pots are made in which butter is brought from Bretagne: Theſe pots themſelves are exceeding good crucibles; and they are almoſt the only ones that are capable of holding glaſs of lead in fuſion, without being penetrated by it.

For the roaſting of ores, that is, freeing them by the help of fire from their ſulphureous and arſenical parts, little cups made of the ſame material with crucibles are uſed; but they are made flat, ſhallow, and wider above than below, that theſe volatile matters may the more freely exhale. Theſe veſſels are called *teſts*, or *ſcorifiers:* They are ſcarce uſed but in the docimaſtic art, that is, in making ſmall aſſays of ores.

The Theory of conſtructing the Furnaces moſt commonly uſed in Chemiſtry.

Skill in conducting and applying fire properly, and determining its different degrees, is of very great conſequence to the ſucceſs of chemical operations.

As it is exceeding difficult to govern and moderate the action of fire, when the veſſels in which any operation is performed are immediately expoſed to it, chemiſts have contrived to convey heat to their veſſels, in nice operations, through different mediums, which they place occaſionly between thoſe veſſels and the fire.

Thoſe

Thoſe intermediate ſubſtances in which they plunge their veſſels are called *baths*. They are either fluid or ſolid: The fluid baths are water, or its vapours. When the diſtilling veſſel is ſet in water, the bath is called *balneum mariæ*, or the water-bath; and the greateſt degree of heat of which it is ſuſceptible is that of boiling water. When the veſſel is expoſed only to the vapours which exhale from water, this forms the vapour-bath: the heat of which is nearly the ſame with that of the *balneum mariæ*. Theſe baths are uſeful for diſtilling eſſential oils, ardent ſpirits, ſweet-ſcented waters; in a word, all ſuch ſubſtances as cannot bear a greater heat without prejudice either to their odour, or to ſome of their other qualities.

Baths may alſo be made of any other fluids, ſuch as oils, mercury, *&c.* which are capable of receiving and communicating much more heat; but they are very ſeldom uſed. When a more conſiderable degree of heat is required, a bath is prepared of any ſolid matter reduced to a fine powder, ſuch as ſand, aſhes, filings of iron, *&c.* The heat of theſe baths may be puſhed ſo far as to make the bottom of the veſſel become faintly red. By plunging a thermometer into the bath, by the ſide of the veſſel, it is eaſy to obſerve the preciſe degree of heat applied to the ſubſtance on which you are working. It is neceſſary that the thermometers employed on this occaſion be conſtructed on good principles, and ſo contrived as to be eaſily compared with thoſe of the moſt celebrated natural philoſophers. Thoſe of the illuſtrious Reaumur are moſt uſed and beſt known, ſo that it would not be amiſs to give them the preference. When a greater heat is required than any of thoſe baths can give, the veſſels muſt be ſet immediately on live-coals, or in a flaming fire: this is called working with a naked fire; and in this caſe it is much more difficult than in the other to determine the degrees of heat.

There are ſeveral ways of applying a naked fire. When the heat or flame is reflected upon the upper part of the veſſel which is expoſed to the fire, this is called a reverberated heat. A melting heat is that which is ſtrong enough to fuſe moſt bodies. A forging heat is that of a fire which is forcibly excited by the conſtant blaſt of a pair of bellows, or more.

There is alſo another ſort of fire which ſerves very commodiouſly for many operations, becauſe it does not require to be fed or frequently mended: This is afforded by a lamp with one or more wicks, and may be called a lamp-heat. It is ſcarce ever employed but to heat baths, in operations which require a gentle and long continued warmth: if it hath any fault, it is that of growing gradually hotter.

All theſe different ways of applying fire require furnaces of different conſtructions: We ſhall therefore deſcribe ſuch as are of principal and moſt neceſſary uſe.

Furnaces muſt be divided into different parts or ſtories, each of which has its particular uſe and name.

The lower part of the furnace deſigned for receiving the aſhes, and giving paſſage to the air, is called the aſh-hole. The aſh-hole is terminated above by a grate, the uſe of which is to ſupport the coals and wood, which are to be burnt thereon: This part is called the fire-place. The fire-place is in like manner terminated above by ſeveral iron bars, which lie quite a-croſs it from right to left, in lines parallel to each other: The uſe of theſe bars is to ſuſtain the veſſels in which the operations are to be performed. The ſpace above theſe bars to the top of the furnace is the upper ſtory, and may be called the laboratory of the furnace. Laſtly, ſome furnaces are quite covered above, by means of a kind of vaulted roof called the dome.

Furnaces have moreover ſeveral apertures: one of theſe is at the aſh-hole, which gives paſſage to the air, and through which the aſhes that fall through the grate are raked out; this aperture is called the aſh-hole door: another is at the fire-place, through which the fire is ſupplied with fuel, as occaſion requires; this is called the mouth or door of the fire-place, or the ſtoke-hole: there is a third in the upper ſtory, through which the neck of the veſſel paſſes; and a fourth in the dome, for carrying off the fuliginoſities of combuſtible matters, which is called the chimney.

To conclude, there are ſeveral other openings in the ſeveral parts of the furnace, the uſe whereof is to admit the air into thoſe places, and alſo, as they can be eaſily ſhut, to incite or ſlacken the activity of the fire, and ſo to regulate it; which has procured them the title of *regiſters*. All the other openings of the furnace ſhould be made to ſhut very cloſe, the better to aſſiſt in governing the fire; by which means they likewiſe do the office of regiſters.

In order to our forming a juſt and general idea of the conſtruction of furnaces, and of the diſpoſition of the ſeveral apertures in them, with a view to increaſe or diminiſh the activity of the fire, it will be proper to lay down, as our ground-work, certain principles of natural philoſophy, the truth of which is demonſtrated by experience.

And firſt, every body knows that combuſtible matters will not burn or conſume unleſs they have a free communication with the air; inſomuch that if they be deprived thereof, even when burning moſt rapidly, they will be extinguiſhed at once: that conſequently combuſtion is greatly promoted by the frequent acceſſion of freſh air; and that a ſtream of air, directed ſo as to paſs with impetuoſity through burning fuel, excites the fire to the greateſt poſſible activity.

Secondly, It is certain that the air which touches or comes near ignited bodies is heated, rarefied, and rendered lighter than the air about it; that is, further diſtant from the centre of heat; and conſequently that this air ſo heated and become lighter is neceſſarily determined thereby to aſcend and mount aloft, in order to make room for that which is leſs heated and not ſo light, which by its weight and elaſticity tends to occupy the place quitted by the other. Another conſequence hereof is, that if fire be kindled in a place incloſed every where but above and below, a current of air will be formed in that place, running in a direction from the bottom to the top; ſo that if any light bodies be applied to the opening below, they will be carried up towards the fire; but, on the contrary, if they be held at the opening above, they will be impelled by a force which will drive them up and carry them away from the fire.

Thirdly,

Thirdly, and lastly, it is a truth demonstrated in hydraulics, that the velocity of a given quantity of any fluid, determined to flow in any direction whatever, is so much the greater, the narrower the channel is to which that fluid is confined; and consequently that the velocity of a fluid will be increased by making it run from a wider through a narrower passage.

These principles being established, it is easy to apply them to the construction of furnaces. First, if a fire be kindled in the fire-place of a furnace, which is open on all sides, it burns nearly as if it were in the open air. It has with the surrounding air a free communication; so that fresh air is continually admitted to facilitate the entire combustion of the inflammable matters employed as fuel. But there being nothing to determine that air to pass with rapidity through the fire in this case, it does not at all augment the activity thereof, but suffers it to waste away quietly.

Secondly, If the ash-hole or dome of a furnace in which a fire is burning be shut quite close, then there is no longer any free communication between the air and the fire; if the ash-hole be shut, the air is debarred from having free access to the fire; if the dome be stopt, the egress of the air rarefied by the fire is prevented; and consequently the fire must in either case burn very faintly and slowly, gradually die away, and at last go quite out.

Thirdly, If all the openings of the furnace be wholly closed, it is evident that the fire will be very quickly extinguished.

Fourthly, If only the lateral openings of the fire-place be shut, leaving the ash-hole and upper part of the furnace open; it is plain that the air entering by the ash-hole will necessarily be determined to go out at top, and that consequently a current of air will be formed, which will pass through the fire, and make it burn briskly and vigorously.

Fifthly, If both the ash-hole and the upper story of the furnace be of some length, and form canals either cylindric or prismatic, then the air being kept in the same direction through a longer space, the course of its stream will be both stronger and better determined, and consequently the fire will be more animated by it.

Sixthly, and lastly, if the ash hole and the upper part of the furnace, instead of being cylindric or prismatic canals, have the form of truncated cones or pyramids, standing on their bases, and so ordered that the upper opening of the ash-hole adjoining to the fire-place may be wider than the base of the superior cone or pyramid; then the stream of air, being forced to pass incessantly from a larger channel through a smaller, must be considerably accelerated, and procure to the fire the greatest activity which it can receive from the make of a furnace.

The materials fittest for building furnaces are, 1. Bricks, joined together with potters clay mixed with sand, and moistened with water. 2. Potters clay mingled with potsherds, moistened with water, and baked in a violent fire. 3. Iron; of which all furnaces may be made; with this precaution, that the inside be provided with a great many prominent points, as fastenings for a coat of earth, with which the internal parts of the furnace must necessarily be covered to defend it from the action of the fire.

The reverberating furnace is one of those that are most employed in chemistry; it is proper for distillations by the retort, and should be constructed in the following manner.

First, The use of the ash-hole being, as was said, to give passage to the air, and to receive the ashes, no bad consequence can attend its being made pretty high: It may have from twelve to twenty or twenty-four inches in heighth. Its aperture should be wide enough to admit billets of wood when a great fire is to be made.

Secondly, The ash-hole must be terminated at its upper part by an iron grate, the bars of which should be very substantial, that they may resist the action of the fire: this grate is the bottom of the fire-place, and destined to support the coals. In the lateral part of the fire-place, and nearly about the same height with the grate, there should be a hole of such a size that it may easily admit charcoal, as well as little tongs and shovels for managing the fire. This aperture or mouth of the fire-place should be perpendicularly over the mouth of the ash-hole.

Thirdly, from six to eight or ten inches high above the grate, over the ash-hole, little apertures must be made in the walls of the furnace, of eight or ten lines in diameter, an inch from one another, and those in one side must be diametrically opposite to those in the other. The use of these holes is to receive bars of iron for the retort to rest on; which should be, as was said, at different heights, in order to accommodate retorts of different sizes. At the upper extremity of this part of the furnace, which reaches from the iron bars to the top, the heighth whereof should be somewhat less than the width of the furnace, must be cut a semi-circular aperture for the neck of the retort to come through. This hole must by no means be over the doors of the fire-place and ash-hole; for then, as it gives passage to the necks of the retorts, it must of course be opposite to the receiver, and in that case the receiver itself would stand over against those two apertures; which would be attended with this double inconvenience, that the receiver would not only grow very hot, but greatly embarrass the operator, whose free access to the fire-place and ash-hole would be thereby obstructed. It is proper therefore, that the semi-circular cut we are speaking of be so placed, that, when the greatest ballons are luted to the retort, they may leave an open passage to the fire-place or ash-hole.

Fourthly, in order cover in the laboratory of the reverberating furnace, there must be a roof made for it in the form of a cupola, or concave hemisphere, having the same diameter as the furnace. This dome should have a semi-circular cut in its rim answering to that above-directed to be made in the upper extremity of the furnace, so that, when adjusted to each other, the two together may form a circular hole for the neck of the retort to pass through. At the top of this dome there must also be a circular hole of three or four inches diameter, carrying a short tapering funnel of the same diameter, and three inches high, which will serve for a chimney

chimney to carry off all fuliginofities, and accelerate the current of the air. This paffage may be fhut at pleafure with a flat cover. Moreover, as it is neceffary that the dome fhould be taken off and put on with eafe, it fhould have two ears or handles for that purpofe: a portative or moveable furnace fhould alfo have a pair of handles fixed oppofite to each other between the afh-hole and the fire place.

Sixthly and laftly, a conical canal muft be provided of about three foot long, and fufficiently wide at its lower end to admit the funnel of the aperture at the top of the dome. This conical tube is to be applied to the dome when the fire is required to be extremely active: it tapers gradually from its bafe upwards, and breaks off as if truncated at top, where it fhould be about two inches wide.

Befides the apertures already mentioned as neceffary to a reverberating furnace, there muft alfo be many other fmaller holes made in its afh-hole, fire-place, laboratory, and dome, which muft all be fo contrived as to be eafily opened and fhut with ftopples of earth: thefe holes are the regifters of the furnace, and ferve to regulate the activity of the fire according to the principles before laid down.

When the action of the fire is required to be exactly uniform and very brifk, it is neceffary to ftop carefully with moift earth all the little chinks in the juncture of the dome with the furnace, between the neck of the retort and the circular hole through which it paffes, and which it never fills exactly, and laftly the holes which receive the iron bars that fuftain the retort.

It is proper to have in a laboratory feveral reverberating furnaces of different magnitudes; becaufe they muft be proportioned to the fize of the retorts employed. The retort ought to fill the furnace, fo as to leave only the diftance of an inch between it and the infide of the furnace.

Yet when the retort is to be expofed to a moft violent fire, and efpecially when it is required that the heat fhall act with equal force on all parts of the furnace, and as ftrongly on its vault as on its bottom, a greater diftance muft be left between the retort and the infide of the furnace; for then the furnace may be filled with coals, even to the upper part of the dome. If moreover fome pieces of wood be put into the afh-hole, the conical canal fitted on to the funnel of the dome, and all the apertures of the furnace exactly clofed, except the afh-hole and the chimney, the greateft heat will then be excited that this furnace can produce.

The furnace now defcribed may alfo be employed in many other chemical operations. If the dome be laid afide, an alembic may very well be placed therein: but then the fpace, which will be left between the body of the alembic and the top of the upper part of the furnace, muft be carefully filled up with Windfor-loam moiftened; for without that precaution the heat would foon reach the very head, which ought to be kept as cool as poffible, in order to promote the condenfation of the vapours.

On this occafion therefore it will be proper to leave no holes open in the fire-place, but the lateral ones; of which alfo thofe over againft the receiver muft be ftopped.

A pot or broad-brimmed earthen pan may be placed over this furnace, and being fo fitted to it as to clofe the upper part thereof accurately, and filled with fand, may ferve for a fand-heat to diftill with.

The bars defigned to fupport diftilling veffels being taken out, a crucible may ftand therein, and many operations be performed that do not require the utmoft violence of fire. In a word, this furnace is one of the moft commodious that can be, and more extenfively ufeful than any other.

The melting furnace is defigned for applying the greateft force of heat to the moft fixed bodies, fuch as metals and earths. It is never employed in diftilling: it is of no ufe but for calcination and fufion; and confequently need not admit any veffels but crucibles.

The afh-hole of this furnace differs from that of the reverberating furnace only in this, that it muft be higher, in order to raife the fire-place to a level with the artift's hand; becaufe in that all the operations of this furnace are performed. The afh-hole therefore muft be about three foot high: and this height procures it moreover the advantage of a good draught of air. For the fame reafon, and in confequence of the principles we laid down, it fhould be fo built that its width leffening infenfibly from the bottom to the top, it may be narrower where it opens into the fire-place than any where below.

The afh-hole is terminated at its upper end, like that of the reverberating furnace, by a grate which ferves for the bottom of the fire-place, and ought to be very fubftantial that it may refift the violence of the fire. The infide of this furnace is commonly an elliptic curve; becaufe it is demonftrated by mathematicians, that furfaces having that curvature reflect the rays of the fun, or of fire, in fuch a manner, that, meeting in a point or a line, they produce there a violent heat. But to anfwer this purpofe, thofe furfaces muft be finely polifhed; an advantage hardly procureable to the internal furface of this furnace, which can be made of nothing but earth: befides, if it were poffible to give it a polifh, the violent action of the fire that muft be employed in this furnace would prefently deftroy it. Yet the elliptical figure muft not be entirely difregarded: for, if care be taken to keep the internal furface of the furnace as fmooth as poffible, it will certainly reflect the heat pretty ftrongly, and collect it about the center.

The fire-place of this furnace ought to have but four apertures.

Firft, that of the lower grate, which communicates with the afh-hole.

Secondly, a door in its fore-fide, through which may be introduced coals, crucibles, and tongs for managing them: this aperture fhould be made to fhut exactly with a plate of iron, having its infide coated with earth, and turning on two hinges fixed to the furnace.

Thirdly, over this door a hole flanting downwards towards the place where the crucible is to ftand. The ufe of this hole is to give the operator an opportunity of examining

amining the condition of the matters contained in his crucible, without opening the door of the fire-place: this hole ſhould be made to open and ſhut eaſily, by means of a ſtopple of earth.

Fourthly, a circular aperture of about three inches wide in the upper part or vault of the furnace, which ſhould gradually leſſen and terminate, like that of the dome of the reverberating furnace, in a ſhort conical funnel of abount three inches long, and fitted to enter the conical pipe before deſcribed, which is applied when the activity of the fire is to be increaſed.

When this furnace is to be uſed, and a crucible to be placed in it, care muſt be taken to ſet on the grate a cake of baked earth ſomewhat broader than the foot of the crucible. The uſe of this ſtand is to ſupport the crucible, and raiſe it above the grate, for which purpoſe it ſhould be two inches thick. Were it not for this precaution, the bottom of the crucible, which would ſtand immediately on the grate, could never be thoroughly heated, becauſe it would be always expoſed to the ſtream of cold air which enters by the aſh-hole. Care ſhould alſo be taken to heat this earthen bottom red-hot before it be placed in the furnace, in order to free it from any humidity, which might otherwiſe happen to be driven againſt the crucible during the operation, and occaſion its breaking.

We omitted to take notice, in ſpeaking of the aſh hole, that, beſides its door, it ſhould have about the middle of its height a ſmall hole, capable of receiving the noſel of a good perpetual bellows, which is to be introduced into it and worked, after the door is exactly ſhut, when it is thought proper to excite the activity of the fire to the utmoſt violence.

The forge is only a maſs of bricks of about three foot high, along whoſe upper ſurface is directed the noſe or pipe of a pair of large perpetual bellows, ſo placed that the operator may eaſily blow the fire with one hand. The coals are laid on the hearth of the forge near the noſe of the bellows; they are confined, if neceſſary, to prevent their being carried away by the wind of the bellows, within a ſpace incloſed by bricks; and then by pulling the bellows the fire is continually kept up in its greateſt activity. The forge is of uſe when there is occaſion to apply a great degree of heat ſuddenly to any ſubſtance, or when it is neceſſary that the operator be at liberty to handle frequently the matters which he propoſes to fuſe or calcine.

The cupelling furnace is that in which gold and ſilver are purified, by the means of lead, from all alloy of other metallic ſubſtances. This furnace muſt give a heat ſtrong enough to vitrify lead, and therewith all the alloy which the perfect metals may contain. This furnace is to be built in the following manner.

Firſt, of thick iron-plates, or of ſome ſuch compoſition of earth as we recommended for the conſtruction of furnaces, muſt be formed a hollow quadrangular priſm, whoſe ſides may be about a foot broad, and from ten to eleven inches high; and extending from thence upwards may converge towards the top, ſo as to form a pyramid truncated at the height of ſeven or eight inches, and terminated by an aperture of the width of ſeven or eight inches every way. The lower part of the priſm is terminated and cloſed by a plate of the ſame materials of which the furnace is conſtructed.

Secondly, in the fore-ſide or front of this priſm there is an opening of three or four inches in height by five or ſix inches in breadth: this opening, which ſhould be very near the bottom, is the door of the aſh-hole. Immediately over this opening is placed an iron grate, the bars of which are quadrangular priſms of half an inch ſquare, laid parallel to each other, and about eight or nine inches aſunder, and ſo diſpoſed that two of their angles are laterally oppoſite, the two others looking one directly upwards, and the other downwards. As in this ſituation the bars of the grate preſent to the fire-place very oblique ſurfaces, the aſhes and very ſmall coals do not accumulate between them, or hinder the free entrance of the air from the aſh-hole. This grate terminates the aſh-hole at its upper part, and ſerves for the bottom of the fire-place.

Thirdly, three inches, or three and a half, above the grate, there is in the fore-ſide of the furnace another opening terminated by an arch for its upper part, which conſequently has the figure of a ſemi-circle: it ought to be four inches wide at bottom, and three inches and an half high at its middle. This opening is the door of the fire-place; yet it is not intended for the ſame uſes as the door of the fire-place in other furnaces: the purpoſe for which it is actually deſtined ſhall be explained when we come to ſhew how the furnace is to be uſed. An inch above the door of the fire-place, ſtill in the foreſide of the furnace, are two holes of about an inch diameter, and at the diſtance of three inches and a half from each other, to which anſwer two other holes of the ſame ſize, made in the hinder part, directly oppoſite to theſe. There is, moreover, a fifth hole of the ſame width about an inch above the door of the fire-place. The deſign of all theſe holes ſhall be explained when we deſcribe the manner in which theſe furnaces are to be uſed.

Fourthly, the fore-part of the furnace is bound by three iron braces, one of which is fixed juſt below the door of the aſh hole; the ſecond occupies the whole ſpace between the aſh-hole door and the door of the fire-place, and has two holes in it, anſwering to thoſe which we directed to be made in the furnace itſelf about this place; and the third is placed immediately over the door of the fire-place. Theſe braces muſt extend from one corner of the front of the furnace to the other, and be faſtened thereto with iron pins, in ſuch a manner that their ſides next to the doors may not lie quite cloſe to the body of the furnace, but form a kind of grooves for the iron plates to ſlide in, that are deſigned to ſhut the two doors of the furnace when it is neceſſary. Each of theſe iron plates ſhould have a handle, by which it may be conveniently moved; and to each door there ſhould be two plates, which meeting each other, and joining exactly in the middle of the door-place, may ſhut it very cloſe. Each of the two plates belonging to the door of the fire-place ought to have a hole in its upper part; one of theſe holes ſhould be a ſlit of about two lines wide, and half an inch long; the other may be a ſemi-circular opening of one inch in height and two in breadth.

breadth. These holes should be placed so that neither of them may open into the fire-place when the two plates are joined together in the middle of the door to shut it close.

Fifthly, to terminate the furnace above, there must be a pyramid, formed of the same materials with the furnace, hollow, quadrangular, three inches high, on a base of seven inches, which base must exactly fit the upper opening of the furnace: the top of this pyramidal cover must end in a tube of three inches in diameter and two in height, which must be almost cylindrical, and yet a little inclining to the conical form. This tube serves, as in the furnaces already described, to carry the conical funnel, which is fitted to the upper part when a fire of extraordinary activity is wanted.

The furnace thus constructed is fit to serve all the purposes for which it is designed; yet, before it can be used, another piece must be provided, which, though it does not properly belong to the furnace, is nevertheless necessary in all the operations performed by it; and that is a piece contrived to contain the cupels, or other vessels which are to be exposed to the fire in this furnace. It is called a *muffle*, and is made in the following manner.

On an oblong square, of four inches in breadth, and six or seven in length, a concave semi-cylinder is erected, in the form of a vault, which makes a semi-circular canal, open at both ends. One of these is almost entirely closed, except that near the bottom two small semi-circular holes are left. In each of its sides likewise two such holes are made, and the other end is left quite open.

The muffle is intended to bear and communicate the fiercest heat; and therefore it must be made thin, and of an earth that will resist the violence of fire, such as that of which crucibles are made. The muffle being thus constructed, and then well baked, is fit for use.

When it is to be used, it must be put into the furnace by the upper opening, and set upon two iron bars, introduced through the holes made for that purpose below the door of the fire-place. The muffle must be placed on these bars in the fire-place, in such a manner that its open end shall stand next to and directly against the door of the fire-place, and may be joined to it with lute. Then the cupels are ranged in it, and the furnace is filled up, to the height of two or three inches above the muffle, with small coals not bigger than a walnut, to the end that they may lie close round the muffle, and procure it an equal heat on every side. The chief use of the muffle is to prevent the coals and ashes from falling into the cupels, which would be very prejudicial to the operations carrying on in them: for the lead would not vitrify as it ought, because the immediate contact of the coals would continually restore its phlogiston; or else the glass of lead, which ought to penetrate and pass through the cupels, would be rendered incapable of so doing; because the ashes mixing therewith would give it such a consistence and tenacity as would destroy that property, or at least considerably lessen it. The openings, therefore, which are left in the lower part of the muffle, should not be so high as to admit coals or ashes to get into the cupels; the use of them is to procure an easier passage for the heat and the air to those vessels. The muffle is left quite open in its fore-part, that the operator may be at liberty to examine what passes in the cupels, to stir their contents, to remove them from one place to another, to convey new matters into them, *&c.* and also to promote the free access of the air, which must concur with the fire towards the evaporation necessary to the vitrification of lead; which air, if fresh were not often enough admitted, would be incapable of producing that effect; because it would soon be loaded with such a quantity of vapours that it could not take up any more.

The government of the fire in this furnace is founded on the general principles above laid down for all furnaces. Yet as there are some little differences, and as it is very essential to the success of the operations for which this furnace is intended, that the artist should be absolutely master of his degree of heat, we shall in few words shew how that may be raised or lowered.

When the furnace is filled with coals and kindled, if the door of the ash-hole be set wide open, and that of the fire-place shut very close, the force of the fire is increased; and if, moreover, the pyramidal cover be put on the top, and the conical funnel added to it, the fire will become still more fierce.

Seeing the matters contained in this furnace are encompassed with fire on all sides, except in the fore part opposite to the door of the fire-place, and as there are occasions which require that the force of the fire should be applied to this part also, an iron box, of the shape and size of the door, hath been contrived to answer that purpose. This box is filled with lighted coals, and applied immediately to the door-place, by which means the heat there is considerably augmented. This help may be made use of at the beginning of the operation, in order to accelerate it, and bring the heat sooner to the desired degree; or in case a very fierce heat be required; or at a time when the air being hot and moist will not make the fire burn with the necessary vigour.

The heat may be lessened, by removing the iron box, and shutting the door of the fire-place quite close. It may be still further and gradually diminished, by taking off the conical funnel from the top; by shutting the door of the fire-place with one of its plates only, that which has the least, or that which has the greatest aperture in it; by taking off the pyramidal cover; by shutting the ash-hole door wholly or in part; and lastly, by setting the door of the fire-place wide open: but, in this last case, the cold air penetrates into the cavity of the muffle, and refrigerates the cupels more than is almost ever necessary. If it be observed, during the operation, that the muffle grows cold in any particular part, it is a sign there is a vacuity left by the coals in that place: in this case an iron wire must be thrust into the furnace, through the hole which is over the door of the fire-place, and the coals stirred therewith, so as to make them fall into their places and fill up the vacant interstices.

It is proper to observe, that, besides what has been said concerning the ways of increasing the activity of the fire in the cupelling furnace, several other causes also may concur to procure to the matters contained in the muffle a greater degree of heat: for example, the smaller the muffle is, the wider and more numerous the holes in it are;

are; the nearer to its bottom, or further end, the cupels are placed, the more will the matters therein contained be affected with heat.

Besides the operations to be performed by the cupel, this furnace is very useful, and even necessary, for many chemical experiments; such, for instance, as those relating to sundry vitrifications and enamelling. As it is pretty low, the best way is to place it, when it is to be used, on a base of brick-work that may raise it to a level with the operator's hand.

A lamp-furnace is exceeding useful for all operations that require only a moderate, but long continued degree of heat. The furnace for working with a lamp heat is very simple: it consists only of a hollow cylinder, from fifteen to eighteen inches high, and five or six in diameter, having at its bottom an aperture large enough for a lamp to be introduced and withdrawn with ease. The lamp must have three or four wicks, to the end that by lighting more or fewer of them a greater or less degree of heat may be produced. The body of the furnace must moreover have several small holes in it, in order to supply the flame of the lamp with air enough to keep it alive.

On the top of this furnace stands a bason five or six inches deep, which ought to fill the cavity of the cylinder exactly, and to be supported at its circumference by a rim which may entirely cover and close the furnace: The use of this bason is to contain the sand through which the lamp-heat is usually conveyed.

Besides this, there must be a kind of cover or dome made of the same material with the furnace, and of the same diameter with the sand-bath, without any other opening than a hole, nearly circular, cut in its lower extremity. This dome is a sort of reverberatory, which serves to confine the heat and direct it towards the body of the retort; for it is used only when something is to be distilled in a vessel of this fashion; and then the hole at its bottom serves for a passage to the neck of the retort. This dome should have an ear or handle, for the conveniency of putting it on and taking it off with ease.

Of Lutes.

Chemical vessels, especially such as are made of glass, and the earthen vessels commonly called stone-ware, are very subject to break when exposed to sudden heat or cold; whence it comes that they often crack when they begin to heat, and also when being very hot they happen to be cooled, either by fresh coals thrown into the furnace, or by the access of cold air. There is no way to prevent the former of these accidents, but by taking the pains to warm your vessel very slowly, and by almost insensible degrees. The second may be avoided by coating the body of the vessel with a paste or lute, which being dried will defend it against the attacks of cold.

The fittest stuff for coating vessels is a composition of fat earth, Windsor-loam, fine sand, filings of iron, or powdered glass, and chopped cow's hair, mixed and made into a paste with water. This lute serves also to defend glass vessels against the violence of the fire, and to prevent their melting easily.

In almost all distillations it is of great consequence, as hath been said, that the neck of the distilling vessel be exactly joined with that of the receiver into which it is introduced, in order to prevent the vapours from escaping into the air and so being lost: And this junction is effected by means of a lute.

A few slips of paper, applied round the neck of the vessels with common size, will be sufficient to keep in such vapours as are aqueous, or not very spirituous.

If the vapours are more acrid and more spirituous, recourse may be had to slips of bladder long steeped in water, which, containing a sort of natural glue, close the junctures of the vessels very well.

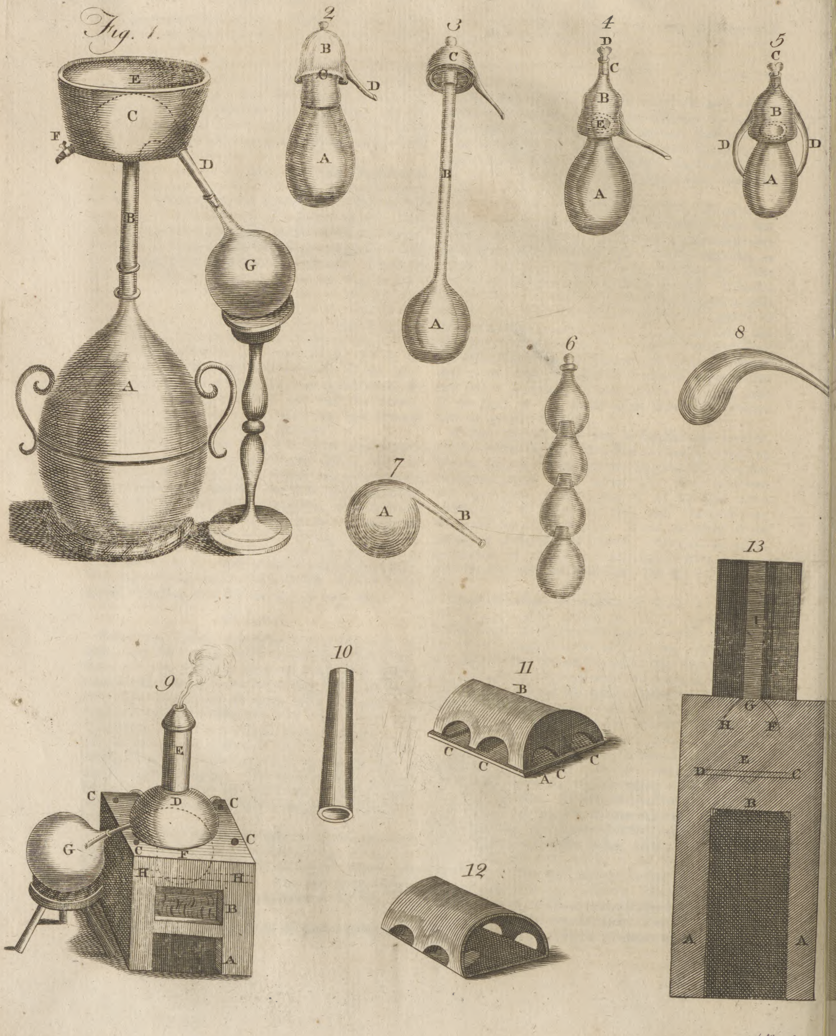
If it be required to confine vapours of a still more penetrating nature, it will be proper to employ a lute that quickly grows very hard; particularly a paste made with quick-lime and any sort of jelly, whether vegetable or animal; such as the white of an egg, stiff size, *&c.* This is an excellent lute, and not easily penetrated. It is also used to stop any cracks or fractures that happen to glass vessels. But it is not capable of resisting the vapours of mineral acid spirits, especially when they are strong and smoking: For that purpose it is necessary to incorporate the other ingredients thoroughly with fat earth softened with water; and even then it frequently happens that this lute is penetrated by acid vapours, especially those of the spirit of salt, which of all others are confined with the greatest difficulty.

In such cases its place may be supplied with another, which is called fat lute, because it is actually worked up with fat liquors. This lute is composed of a very fine cretaceous earth, called tobacco-pipe clay, moistened with equal parts of the drying oil of lint-seed, and a varnish made of amber and gum copal It must have the consistence of a stiff paste. When the joints of the vessels are closed up with this lute, they may, for greater security, be covered over with slips of linen smeared with the lute made of quick-lime and the white of an egg.

Chemical vessels are liable to be broken in an operation by other causes besides the sudden application of heat or cold. It frequently happens that the vapours of the matters, exposed to the action of fire, rush out with such impetuosity, and are so elastic, that finding no passage through the lute with which the joints of the vessels are closed, they burst the vessels themselves, sometimes with explosion and danger to the operator.

To prevent this inconvenience, it is necessary, that in every receiver there be a small hole, which being stopped only with a little lute may easily be opened and shut again as occasion requires. It serves for a vent-hole to let out the vapours, when the receiver begins to be too much crowded with them. Nothing but practice can teach the artist when it is requisite to open this vent. If he hits the proper time, the vapours commonly rush out with rapidity, and a considerable hissing noise; and the vent should be stopped again as soon as the hissing begins to grow faint. The lute employed to stop this small hole ought always to be kept so ductile, that by taking the figure of the hole exactly it may entirely stop it. Besides, if it should harden upon the glass, it would stick so fast, that it would be very difficult to remove it without breaking

Plate. LXIV



A.B. Sc.

ing the veſſel. This danger is eaſily avoided by making uſe of the fat lute, which continues pliant for a long time, when it is not expoſed to an exceſſive heat.

This way of ſtopping the vent-hole of the receiver has yet another advantage: For if the hole be of a proper width, as a line and half, or two lines, in diameter, then when the vapours are accumulated in too great a quantity, and begin to make a great effort againſt the ſides of the receiver, they puſh up the ſtopple, force it out, and make their way through the vent-hole: So that by this means the breaking of the veſſels may always be certainly prevented. But great care muſt be taken that the vapours be not ſuffered to eſcape in this manner, except when abſolute neceſſity requires it; for it is generally the very ſtrongeſt and moſt ſubtile part of a liquor which is thus diſſipated and loſt.

Heat being the chief cauſe that puts the elaſticity of the vapours in action, and prevents their condenſing into a liquor, it is of great conſequence in diſtillation that the receiver be kept as cool as poſſible. With this view a thick plank ſhould be placed between the receiver and the body of the furnace, to intercept the heat of the latter, and prevent its reaching the former. As the vapours themſelves riſe very hot from the diſtilling veſſel, they ſoon communicate their heat to the receiver, and eſpecially to its upper part, againſt which they ſtrike firſt. For this reaſon it is proper, that linen cloths dipt in very cold water be laid over the receiver, and frequently ſhifted. By this means the vapours will be conſiderably cooled, their elaſticity weakened, and their condenſation promoted.

By what hath been ſaid in this firſt part, concerning the properties of the principal agents in chemiſtry, the conſtruction of the moſt neceſſary veſſels and furnaces, and the manner of uſing them, we are ſufficiently prepared for proceeding directly to the operations, without being obliged to make frequent and long ſtops, in order to give the neceſſary explanations on thoſe heads.

Nevertheleſs, we ſhall take every proper occaſion to extend the theory here laid down, and to improve it by the addition of ſeveral particulars, which will find their places in our treatiſe of chemical operations.

PART II. PRACTICE of CHEMISTRY.

Of the Vitriolic Acid.

To extract Vitriol from the Pyrites.

Take any quantity you pleaſe of iron pyrites; leave them for ſome time expoſed to the air: They will crack, ſplit, loſe their brightneſs, and fall into powder. Put this powder into a glaſs cucurbit, and pour upon it twice its weight of hot water; ſtir the whole with a ſtick, and the liquor will grow turbid. Pour it while it is yet warm into a glaſs funnel lined with brown filtering paper; and having placed your funnel over another glaſs cucurbit, let the liquor drain into it. Pour more hot water on the powdered pyrites, filter as before, and ſo go on, every time leſſening the quantity of water, till that which comes off the pyrites appears to have no aſtringent vitriolic taſte.

twice its weight of hot water; evaporate and cryſtalliſe as before. Repeat the ſame operation till the liquor will yield no more cryſtals: it will then be very thick, and goes by the name of *mother of nitre.*

Earths and ſtones that have been impregnated with animal or vegetable juices ſuſceptible of putrefaction, and have been long expoſed to the air, but ſheltered from the ſun and rain, are thoſe which yield the greateſt quantity of nitre. But all ſorts of earths and ſtones are not equally fit to produce it. None is ever found in flints or ſands of a cryſtalline nature.

Some earths and ſtones abound ſo with nitre, that it effloreſces ſpontaneouſly on their ſurface, in the form of a cryſtalline down. This nitre may be collected with brooms, and accordingly has the name of *ſalt-petre ſweepings.* Some of this ſort is brought from India.

The proceſs by which our ſalt-petre makers extract nitre in quantities, out of rubbiſh and nitrous earths, is very nearly the ſame with that here ſet down: ſo that we ſhall not enter into a particular account of it. We ſhall only take notice of one thing, which it is of ſome conſequence to know; namely, that there is no nitrous earth which does not contain ſea ſalt alſo. The greateſt quantities of this ſalt are to be found in thoſe earths which have been drenched with urine or other animal excrements. Now, as the rubbiſh of old houſes in great cities is in this claſs, it comes to paſs, that when the ſalt-petre workers evaporate a nitrous lixivium drawn from that rubbiſh, as ſoon as the evaporation is brought to a certain pitch, a great many little cryſtals of ſea-ſalt form in the liquor, and fall to the bottom of the veſſel.

The ſalt-petre workers in France call theſe ſaline particles *the grain*, and take great care to ſeparate them from the liquor, (which as long as it continues hot keeps the ſalt-petre diſſolved) before they ſet it to cryſtalliſe. This fact ſeems a little ſingular, conſidering that ſea-ſalt diſſolves in water more eaſily than ſalt-petre, and cryſtalliſes with more difficulty.

In order to diſcover the cauſe of this phenomenon, we muſt recollect, firſt, that water can keep but a determinate quantity of any ſalt in ſolution, and that if water fully ſaturated with a ſalt be evaporated, a quantity of ſalt will cryſtalliſe in proportion to the quantity of water evaporated. Secondly, that thoſe ſalts which are the moſt ſoluble in water, particularly thoſe which run in the air, will diſſolve in cold and in boiling water equally; whereas much greater quantities of the other ſalts will diſſolve in hot and boiling water than in cold water. Theſe things being admitted, when we know that ſea-ſalt is one of the firſt ſort, and ſalt-petre of the ſecond, the reaſon why ſea-ſalt precipitates in the preparation of ſalt-petre appears at once. For,

When the ſolution of ſalt-petre and ſea ſalt comes to be evaporated to ſuch a degree that it contains as much ſea ſalt as it poſſibly can, this ſalt muſt begin to cryſtalliſe, and continue to do ſo gradually as the evaporation advances. But becauſe at the ſame time it does not contain as much ſalt-petre as it can hold, ſeeing it is capable of diſſolving a much greater quantity thereof when it is boiling hot than when it is cold, this laſt named ſalt will not cryſtalliſe ſo ſoon. If the evaporation were continued till the caſe of the ſalt-petre came to be the ſame with that of the ſea ſalt, then the ſalt-petre alſo would begin to cryſtalliſe gradually in proportion to the water evaporated, and the two ſalts would continue cryſtalliſing promiſcuouſly together: but it is never carried ſo far; nor is it ever neceſſary; for as the water cools it becomes more and more incapable of holding in ſolution the ſame quantity of ſalt-petre as when it was boiling hot.

And then comes the very reverſe, with regard to the cryſtalliſing of the two ſalts; for then the ſalt-petre ſhoots, and not the ſea-ſalt. The reaſon of this fact alſo is founded on what has juſt been ſaid. The ſea-ſalt, of which cold water will diſſolve as much as boiling water, and which owed its cryſtalliſing before only to the evaporation, now ceaſes to cryſtalliſe as ſoon as the evaporation ceaſes; while the ſalt-petre, which the water kept diſſolved only becauſe it was boiling hot, is forced to cryſtalliſe merely by the cooling of the water.

When the ſolution of ſalt-petre has yielded as many cryſtals of that ſalt as it can yield by cooling, it is again evaporated, and being then ſuffered to cool yields more cryſtals And thus they continue evaporating and cryſtalliſing till the liquor will afford no more cryſtals. It is plain, that as the ſalt-petre cryſtalliſes, the proportion of ſea-ſalt to the diſſolving liquor increaſes; and as a certain quantity of water evaporates alſo during the time employed in cryſtalliſing the ſalt-petre, a quantity of ſea-ſalt, proportioned to the water ſo evaporating, muſt cryſtalliſe in that time: and this is the reaſon why ſalt-petre is adulterated with a mixture of ſea-ſalt. It likewiſe follows, that the laſt cryſtals of nitre, obtained from a ſolution of ſalt-petre and ſea-ſalt, contain much more ſea-ſalt than the firſt.

From all that has been ſaid concerning the cryſtalliſation of ſalt-petre and ſea-ſalt, it is eaſy to deduce the proper way of purifying the former of theſe two ſalts from a mixture of the latter. For this purpoſe the ſalt-petre to be refined need only be diſſolved in fair water. The proportion between the two ſalts in this ſecond ſolution is very different from what it was in the former; for it contains no more ſea-ſalt than what had cryſtalliſed along with the ſalt-petre under favour of the evaporation, the reſt having been left diſſolved in the liquor that refuſed to yield any more nitrous cryſtals.

As there is therefore a much greater quantity of ſalt-petre than of ſea-ſalt in this ſecond ſolution, it is eaſy to evaporate it to ſuch a degree that a great deal of ſalt-petre ſhall cryſtalliſe, while much more of the water muſt neceſſarily be evaporated before any of the ſea-ſalt will cryſtalliſe.

However, the ſalt-petre is not yet entirely freed from all mixture of ſea ſalt by this firſt purification; for the the cryſtals obtained from this liquor, in which ſea-ſalt is diſſolved, are ſtill incruſted, and, as it were, infected therewith: hence it comes, that, to refine the ſalt-petre thoroughly, theſe cryſtalliſations muſt be repeated four or five times.

The ſalt-petre men commonly content themſelves with cryſtalliſing it thrice, and call the produce ſalt-petre of the firſt, ſecond, or third ſhoot, according to the number of cryſtalliſations it has undergone. But their beſt

refined

refined salt-petre, even that of the third shooting, is not yet sufficiently pure for chemical experiments that require much accuracy: so that it must be further purified, but still by the same method.

The nitrous acid is not pure in the earths and stones from which it is extracted. It is combined partly with the very earth in which it is formed, and partly with the volatile alkali produced by the putrefaction of the vegetable or animal matters that concurred to its generation. A fixed alkali and quick-lime are added to the lixivium of a nitrous earth, in order to decompose the nitrous salts formed in that earth, and to separate the acid from the volatile alkali and the absorbent earth with which it is united: thence comes that copious sediment which appears in the lye at the beginning of the evaporation. These matters form with that acid a true nitre, much more capable than the original nitrous salts of crystallisation, detonation, and the other properties which are essential thereto. The basis of nitre is therefore a fixed alkali mixed with a little lime.

The mother of nitre, which will yield no more crystals, is brown and thick: by evaporation over a fire it is further inspissated, and becomes a dry, solid body; which however being left to itself soon gives, and runs into a liquor. This water still contains a good deal of nitre, sea-salt, and the acids of these salts united with an absorbent earth. It contains moreover a great deal of a fat, viscid matter, which prevents its crystallising.

All saline solutions in general, after having yielded a certain quantity of crystals, grow thick, and refuse to part with any more, though they still contain much salt. They are all called *mother-waters*, as well as that which hath yielded nitre. The mother-waters of different salts may prove the subjects of curious and useful enquiries.

If a fixed alkali be mixed with the mother of nitre, a copious white precipitate immediately falls, which being collected and dried is called *magnesia*. This precipitate is nothing but the absorbent earth that was united with the nitrous acid, together with a good deal of the lime that was added, and was also united with that acid, from which they are now separated by the fixed alkali, according to the usual laws of affinities or elective attractions.

The vitriolic acid poured upon mother of nitre causes many acid vapours to rise, which are a compound of the nitrous and marine acids, that is, an *aqua regia*. On this occasion also there falls a large quantity of a white powder, which is still called *magnesia*; yet it differs from the former in that it is not, like it, a pure absorbent earth, but combined with the vitriolic acid.

An *aqua regis* may also be drawn from nitrous earths by the force of fire only, without the help of any additament.

To decompose Nitre by means of the Phlogiston. Nitre fixed by Charcoal. Clyssus *of Nitre.* Sal Polychrestum.

Take the purest salt-petre in powder; put it into a large crucible, which it may but half fill; set the crucible in a common furnace, and surround it with coals. When it is red-hot the nitre will melt, and become as fluid as water. Then throw into the crucible a small quantity of charcoal-dust: the nitre and the charcoal will immediately deflagrate with violence; and a great commotion will be raised, accompanied with a considerable hissing, and abundance of black smoke. As the charcoal wastes, the detonation will abate, and cease entirely as soon as the coal is quite consumed.

Then throw into the crucible the same quantity of charcoal-dust as before, and the same phenomena will be repeated. Let this coal also be consumed: then add more, and go on in the same manner till you can excite no further deflagration; always observing to let the burning coal be entirely consumed before you add any fresh. When no deflagration ensues, the matter contained in the crucible will have lost much of its fluidity.

Nitre will not take fire, unless the inflammable matter added to it be actually burning, or the nitre itself red hot, and so thoroughly ignited as immediately to kindle it. Therefore, if you would procure the detonation of nitre with charcoal, and make use of cold charcoal, as in the process, the nitre in the crucible must be red hot, and in perfect fusion: but you may also use live coals, and then the nitre need not be red-hot.

The matter remaining in the crucible after the operation, is a very strong fixed alkali. Being exposed to the air, it quickly extracts the moisture thereof, and runs into a liquor. It is called *alkalizated nitre*, or to distinguish it from nitre alkalizated by other inflammable matters, *nitre fixed by charcoal.*

The nitrous acid is not only dissipated during the deflagration of the nitre, but is even destroyed, and perfectly decomposed. The smoke that rises during the operation has not the least odour of an acid.

In order to collect the vapours discharged by the deflagration of nitre, fit to a tubulated earthen retort two or three large adopters: set the retort in a furnace; and under it make a fire sufficient to keep its bottom moderately red. Then take a small quantity, two or three pinches for example, of a mixture of three parts of nitre with one of charcoal-dust, and drop it into the retort through its tube, which must be uppermost, and immediately stopped close. A detonation instantly ensues, and the vapours that rise from the inflammed mixture of nitre and charcoal, passing out through the neck of the retort into the adopters,, circulate therein for a while, and at last condense into a liquor.

When the detonation is over, and the vapours condensed, or nearly so, drop into the retort another equal quantity of the mixture; and repeat this till you find there is liquor enough in the recipients to be examined with ease and accuracy. This liquor is almost insipid, and shews no tokens of acidity; or at most but very slight ones. It is called *clyssus* of nitre.

Nitre is also decomposed and takes fire by the means of sulphur; but the circumstances and the result differ widely from those produced therewith by charcoal or any other inflammable body.

Nitre deflagrates with sulphur on account of the phlogiston which the latter contains. If one part of sulphur be mixed with two or three parts of nitre, and the mixture thrown by little and little into a red-hot crucible, upon

upon every projection there arises a detonation accompanied with a vivid flame.

The vapours discharged on this occasion have the mingled smell of a sulphureous spirit and spirit of nitre; and if they be collected by means of a tubulated retort, and such an apparatus of vessels as was used in the preceding experiment, the liquor contained in the recipients is found to be an actual mixture of the acid of sulphur, the sulphureous spirit, and the acid of nitre; the first being of greater quantity than the other two, and the second greater than the last.

Nor is the remainder after detonation a fixed alkali, as in the former experiments; but a neutral salt, consisting of the acid of sulphur combined with the alkali of nitre; a sort of vitriolated tartar, known in medicine by the name of *sal polychrestum*.

To decompose Nitre by means of the Vitriolic Acid. The Smoking Spirit of Nitre. Sal de duobus. *The Purification of Spirit of Nitre.*

Take equal parts of well purified nitre and green vitriol: dry the nitre thoroughly, and bruise it to a fine powder. Calcine the vitriol to redness: reduce it likewise to a very fine powder; and mingle these two substances well together. Put the mixture into an earthen long neck, or a good glass retort coated, of such a size that it may be but half full.

Set this vessel in a reverberating furnace covered with its dome; apply a large glass receiver, having a small hole in its body, stopped with a little lute. Let this receiver be accurately luted to the retort with the fat lute, and the joint covered with a slip of canvas smeared with lute made of quick-lime and the white of an egg. Heat the vessels very gradually. The receiver will soon be filled with very dense red vapours, and drops will begin to distill from the nose of the retort.

Continue the distillation, increasing the fire a little when you observe the drops to follow each other but slowly, so that above two thirds of a minute passes between them; and, in order to let out the redundant vapours, open the small hole in the receiver from time to time. Towards the end of the operation raise the fire so as to make the retort red. When you find that, even when the retort is red-hot, nothing more comes over, unlute the receiver, and without delay pour the liquor it contains into a crystal bottle, and close it with a crystal stopple rubbed in its neck with emery. This liquor will be of a reddish yellow colour, smoking exceedingly, and the bottle containing it will be constantly filled with red fumes like those observed in the receiver.

By the process here delivered, a very strong, perfectly dephlegmated, and vastly smoking spirit of nitre is obtained.

When the operation is over, you will find a red mass at the bottom of the retort, cast as it were in a mould. This is a neutral salt of the nature of vitriolated tartar, resulting from the union of the acid of the vitriol with the alkaline basis of the nitre.

The ferruginous basis of the vitriol, which is mixed with this salt, gives it the red colour. To separate it therefrom, you must pulverise it, dissolve it in boiling water, and filter the solution several times through brown paper; because the ferruginous earth of the vitriol is so fine, that some of it will pass through the first time. When the solution is very clear, and deposites no sediment, let it be set to shoot, and it will yield crystals of vitriolated tartar; to which chemists have given the peculiar title of *sal de duobus*.

Nitre may also be decomposed, and its acid obtained, by the interposition of any of the other vitriols, alums, gypsums, boles, clays; in short, by means of any compound in which the vitriolic acid is found, provided it have not a fixed alkali for its basis.

The distillers of *aqua fortis*, who make large quantities at a time, and who use the least chargeable methods, do their business by the means of earths impregnated with the vitriolic acid; such as clays and boles. With these earths they accurately mix the nitre from which they intend to draw their spirit: this mixture they put into large oblong earthen pots, having a very short curved neck, which enters a recipient of the same matter and form. These vessels they place in two rows opposite to each other in long furnaces, and cover them over with bricks cemented with Windsor-loam, which serves for a reverberatory: then they light the fire in the furnace, making it at first very small, only to warm the vessels; after which they throw in wood, and raise the fire till the pots grow quite red-hot, in which degree they keep it up till the distillation is entirely finished.

Most experiments require the spirit of nitre to be absolutely pure; and if it be intended for such, it must be perfectly cleansed from the vitriolic taint.

This is easily effected by mixing your spirit with very pure nitre, and distilling it a second time. The vitriolic acid, with which this spirit of nitre is adulterated, coming in contact with a great quantity of undecomposed nitre, unites with its alkaline basis, and expels a proportionable quantity of the nitrous acid.

Of the Marine Acid.

To extract Sea-salt from Sea-water, and from Brine-springs. Epsom Salt.

Filter the salt-water from which you intend to extract the salt; evaporate it by boiling, till you see on its surface a dark pellicle: this consists wholly of little crystals of salt just beginning to shoot: now slacken the fire, that the brine may evaporate more slowly, and without any agitation. The crystals, which at first were very small, will become larger, and form hollow truncated pyramids, the apices whereof will point downwards, and their bases be even with the surface of the liquor.

These pyramidal crystals are only collections of small cubical crystals concreted into this form. When they have acquired a certain magnitude they fall to the bottom of the liquor. When they come to be in such heaps as almost to reach the surface of the liquor, decant it from them, and continue the evaporation till no more crystals of sea-salt will shoot

The acid of sea salt is scarce ever found either in sea-water or in the earth, otherwise than united with a fixed alkali

alkali of a particular kind, which is its natural basis; and consequently it is in the form of a neutral salt. This salt is plentifully dissolved in the waters of the ocean, and when obtained therefrom bears the name of *sea-salt*. It is also found in the earth in vast crystalline masses, and is then called *sal-gem*; so that sea-salt and sal-gem are but one and the same sort of salt differing very little from each other, except as to the places where they are found.

In the earth are also found springs and fountains, whose waters are strong brines, a great deal of sea-salt being dissolved in them. These springs either rise directly from the sea, or run through some mines of salgem, of which they take up a quantity in their passage.

As the same, or at least nearly the same quantity of sea-salt will continue dissolved in cold water as boiling water will take up, it cannot shoot, as nitre does, by the mere cooling of the water in which it is dissolved: it crystallises only by the means of evaporation, which continually lessens the proportion of the water to the salt; so that it is always capable of containing just so much the less sea-salt the more there is crystallised.

The brine should not boil after you perceive the pellicle of little crystals beginning to form on its surface; for the calmness of the liquor allows them to form more regularly, and become larger. Nor after this should the evaporation be hurried on too fast; for a saline crust would form on the liquor, which, by preventing the vapours from being carried off, would obstruct the crystallisation.

If the evaporation be continued after the liquor ceases to yield any crystals of sea-salt, other crystals will be obtained of an oblong four-sided form, which have a bitter taste, and are almost always moist. This sort of salt is known by the name of *Epsom salt*, which it owes to a salt spring in England, from the water of which it was first extracted. This salt, or rather saline compound, is a congeries of Glauber's salt and sea-salt, in a manner confounded together, and mixed with some of the mother of sea-salt, in which is contained a kind of bituminous matter. These two neutral salts, which constitute the Epsom salt, may be easily separated from each other, by means of crystallisation only. Epsom salt is purgative and bitter; and therefore named *sal catharticum amarum*, or bitter purging salts.

There are different methods used in great works for obtaining sea-salt out of water in which it is dissolved. The simplest and easiest is that practised in France, and in all those countries which are not colder. On the seashore they lay out a sort of broad shallow pits, pans, or rather ponds, which the sea fills with the tide of flood. When the ponds are thus filled, they stop their communication with the sea, and leave the water to evaporate by the heat of the sun; by which means all the salt contained in it necessarily crystallises. These pits are called *salt ponds*. Salt can be made in this way in the summertime only, at least in France, and other countries of the same temperature; for during the winter, when the sun has less power, and rains are frequent, this method is not practicable.

For this reason, as it often rains in the province of Normandy, the inhabitants take another way to extract salt from sea-water. The labourers employed for this purpose raise heaps of sand on the shore, so that the tide waters and drenches them when it flows, and leaves the sand dry when it ebbs. During the interval between two tides of flood the sun and the air easily carry off the moisture that was left, and so the sand remains impregnated with all the salt that was contained in the evaporated water. Thus they let it acquire as much salt as it can by several returns of flood, and then wash it out with fresh water, which they evaporate over a fire in leaden boilers.

To obtain the salt from brine-springs, the water need only be evaporated: but as several of these springs contain too little salt to pay the charges that would be incurred, if the evaporation were effected by the force of fire only, the manufacturers have fallen upon a less expensive method of getting rid of the greatest part of the water, and preparing the brine for crystallisation, in much less time, and with much less fire, than would otherwise have been necessary.

The method consists in making the water fall from a certain height on a great many small spars of wood, which divide it into particles like rain. This is performed under sheds open to all the winds, which pass freely through this artificial shower. By this means the water presents to the air a great extent of surface, being indeed reduced almost entirely to surface, and the evaporation is carried on with great ease and expedition. The water is raised by pumps to the height from which it is intended to fall.

Experiments concerning the decomposition of Sea-salt, by means of the phlogiston. Kunckel's *Phosphorus.*

" Of pure urine that has fermented five or six days take a quantity in proportion to the quantity of phosphorus you intend to make: it requires about one third part of a hogshead to make a dram of phosphorus. Evaporate it in iron pans, till it become clotted, hard, black, and nearly like chimney-soot; at which time it will be reduced to about a sixtieth part of its original weight before evaporation.

" When the urine is brought to this condition, put it in several portions into so many iron pots, under which you must keep a pretty brisk fire so as to make their bottoms red, and stir it incessantly till the volatile salt and the fetid oil be almost wholly dissipated, till the matter cease to emit any smoke, and till it smell like peach-blossoms. Then put out the fire, and pour on the matter, which will now be reduced to a powder, somewhat more than twice its weight of warm water. Stir it about in this water, and leave it to soak therein for twenty-four hours. Pour off the water by inclination; dry the drenched matter, and pulverise it. The previous calcination carries off from the matter about a third of its weight, and the lixiviation washes out half the remainder.

" With what remains thus calcined, washed, and dried, mix half its weight of gravel, or yellow free-stone rasped, having sifted out and thrown away all the finest particles. River-sand is not proper on this occasion, because it flies in a hot fire. Then add to this mixture

mixture a ſixteenth part of its weight of charcoal, made of beech, or of any other wood except oak, becauſe that alſo flies. Moiſten the whole with as much water as will bring it to a ſtiff paſte, by working and kneading it with your hands: Now introduce it into your retort, taking care not to daub its neck. The retort muſt be of the beſt earth, and of ſuch a ſize, that when your matter is in it, a full third thereof ſhall ſtill be empty.

"Place your retort, thus charged, in a reverberating furnace, ſo proportioned, that there may be an interval of two inches all round between the ſides of the furnace and the bowl of the retort, even where it contracts to form the neck, which ſhould ſtand inclined at an angle of ſixty degrees. Stop all the apertures of the furnace, except the doors of the fire-place and aſh-hole.

"Fit on to the retort a large glaſs ballon two thirds full of water, and lute them together, as in diſtilling the ſmoking ſpirit of nitre. In the hinder part of this ballon, a little above the ſurface of the water, a ſmall hole muſt be bored. This hole is to be ſtopped with a ſmall peg of birch-wood, which muſt ſlip in and out very eaſily, and have a ſmall knob to prevent its falling into the ballon. This peg is to be pulled out from time to time, that by applying the hand to the hole it may be known whether the air rarefied by the heat of the retort, iſſues out with too much or too little force.

"If the air ruſhes out with too much rapidity, and with a hiſſing noiſe, the door of the aſh-hole muſt be entirely ſhut, in order to ſlacken the fire. If it do not ſtrike pretty ſmartly againſt the hand, that door muſt be opened wider, and large coals thrown into the fire-place to quicken the fire immediately.

"The operation uſually laſts four and twenty hours; and the following ſigns ſhew that it will ſucceed, provided the retort reſiſt the fire.

"You muſt begin the operation with putting ſome unlighted charcoal in the aſh-hole, and a little lighted charcoal at the door thereof, in order to warm the retort very ſlowly. When the whole is kindled, puſh it into the aſh-hole, and cloſe the door thereof with a tile. This moderate heat brings over the phlegm of the mixture. The ſame degree of heat muſt be kept up four hours, after which ſome coals may be laid on the grate of the fire-place, which the fire underneath will kindle by degrees. With this ſecond heat brought nearer the retort, the ballon grows warm, and is filled with white vapours which have the ſmell of fetid oil. In four hours after, this veſſel will grow cool and clear; and then you muſt open the door of the aſh-hole one inch, throw freſh coals into the fire-place every three minutes, and every time ſhut the door of it, leſt the cold air from without ſhould ſtrike againſt the bottom of the retort and crack it

"When the fire has been kept up to this degree for about two hours, the inſide of the ballon begins to be netted over with a volatile ſalt of a ſingular nature, which cannot be driven up but by a very violent fire, and which ſmells pretty ſtrong of peach-kernels. Care muſt be taken that this concrete ſalt do not ſtop the little hole in the ballon: for in that caſe it would burſt, the retort being then red-hot, and the air exceedingly rarefied. The water in the ballon, being heated by the vicinity of the furnace, exhales vapours which diſſolve this ſprigged ſalt, and the ballon clears up in half an hour after it has ceaſed riſing.

"In about three hours from the firſt appearance of this ſalt, the ballon is again filled with new vapours, which ſmell like ſal ammoniac thrown upon burning coals. They condenſe on the ſides of the receiver into a ſalt which is not branched like the former, but appears in long perpendicular ſtreaks, which the vapours of the water do not diſſolve. Theſe white vapours are the fore-runners of the phoſphorus; and a little before they ceaſe to riſe they loſe their firſt ſmell of ſal ammoniac, and acquire the odour of garlick.

"As they aſcend with great rapidity, the little hole muſt be frequently opened, to obſerve whether the hiſſing be not too ſtrong; for in that caſe it would be neceſſary to ſhut the door of the aſh-hole quite cloſe. Theſe white vapours continue two hours. When you find they ceaſe riſing, make a ſmall paſſage through the dome, by opening ſome of its regiſters, that the flame may juſt begin to draw. Keep up the fire in this mean ſtate till the firſt volatile phoſphorus begin to appear.

"This appears in about three hours after the white vapours firſt begin to riſe. In order to diſcover it, pull out the little birchen peg once every minute, and rub it againſt ſome hot part of the furnace, where it will leave a trail of light, if there be any phoſphorus upon it.

"Soon after you obſerve this ſign, there will iſſue out through the little hole of the ballon a ſtream of bluiſh light, which continues of a greater or ſhorter extent to the end of the operation. This ſtream or ſpout of light does not burn. If you hold your finger againſt it for twenty or thirty ſeconds, the light will adhere to it; and if you rub that finger over your hand, the light will beſmear it, and render it luminous.

"But from time to time this ſtreamer darts out to the length of ſeven or eight inches, ſnapping and emitting ſparks of fire; and then it burns all combuſtible bodies that come in its way. When you obſerve this, you muſt manage the fire very warily, and ſhut the door of the aſh-hole quite cloſe, yet without ceaſing to throw coals into the fire-place every two minutes.

"The volatile phoſphorus continues two hours; after which the little ſpout of light contracts to the length of a line or two: And now is the time for puſhing your fire to the utmoſt: Immediately ſet the door of the aſh-hole wide open, throw billets of wood into it, unſtop all the regiſters of the reverberatory, ſupply the fire-place with large coals every minute: In ſhort, for ſix or ſeven hours all the inſide of the furnace muſt be kept of a white heat, ſo that the retort ſhall not be diſtinguiſhable.

"In this fierce extremity of heat the true phoſphorus diſtills like an oil, or like melted wax: One part thereof floats on the water in the recipient, the other falls to the bottom. At laſt the operation is known to be quite over when the upper part of the ballon, in which the volatile phoſphorus appears condenſed in a blackiſh film, begins to grow red: For this ſhews that the phoſphorus is burnt where the red ſpot appears. You muſt now ſtop all the regiſters, and ſhut all the doors of the furnace, in order to ſmother the fire; and then cloſe up the little hole in

in the ballon with fat lute or bees-wax. In this condition the whole muſt be left for two days; becauſe the veſſels muſt not be ſeparated till they are perfectly cold, leſt the phoſphorus ſhould take fire.

"As ſoon as the fire is out, the ballon, which is then in the dark, preſents a moſt agreeable object: All the empty part thereof above the water ſeems filled with a beautiful blue light; which continues for ſeven or eight hours, or as long as the ballon keeps warm, never diſappearing till it is cooled.

"When the furnace is quite cold, take out the veſſels, and ſeparate them from each other as neatly as poſſible. With a linen cloth wipe away all the black ſtuff you find in the mouth of the ballon; for if that filth ſhould mix with the phoſphorus, it would hinder it from being tranſparent when moulded. This muſt be done with great expedition: After which pour into the ballon two or three quarts of cold water, to accelerate the precipitation of the phoſphorus that ſwims at top. Then agitate the water in the ballon, to rinſe out all the phoſphorus that may ſtick to the ſides; pour out all the water thus ſhaken and turbid, into a very clean earthen pan, and let it ſtand till it grows clear. Then decant this firſt uſeleſs water, and on the blackiſh ſediment left at the bottom of the pan pour ſome boiling water to melt the phoſphorus; which thereupon unites with the fuliginous matter, or volatile phoſphorus, that precipitated with it, both together forming a maſs of the colour of ſlate. When this water in which you have melted the phoſphorus is cool enough, take out the phoſphorus, throw it into cold water, and therein break it into little bits in order to mould it.

"Then take a matras, having a long neck ſomewhat wider next the body than at its mouth: Cut off half the body, ſo as to make a funnel of the neck-part, the ſmaller end of which muſt be ſtopped with a cork. The firſt mould being thus prepared, plunge it endwiſe, with its mouth uppermoſt, in a veſſel full of boiling water, and fill it with that water. Into this funnel throw the little bits of your ſlate-like maſs, which will melt again in this hot water, and fall ſo melted to the bottom of the tube. Stir this melted matter with an iron wire, to promote the ſeparation of the phoſphorus from the fuliginous matter with which it is fouled, and which, being leſs ponderous than the phoſphorus, will gradually riſe above it towards the upper part of the cylinder.

"Keep the water in the veſſel as hot as at firſt, till on taking out the tube you ſee the phoſphorus clean and tranſparent. Let the clear tube cool a little, and then ſet it in cold water, where the phoſphorus will congeal as it cools. When it is perfectly congealed, pull out the cork, and with a ſmall rod near as big as the tube, puſh the cylinder of phoſphorus towards the mouth of the funnel, where the feculency lies. Cut off the black part of the cylinder, and keep it apart: For when you have got a quantity thereof, you may melt it over again in the ſame manner, and ſeparate the clean phoſphorus which it ſtill contains. As to the reſt of the cylinder which is clean and tranſparent, if you intend to mould it into ſmaller cylinders, you may cut it in ſlices, and melt it again by the help of boiling water in glaſs tubes of ſmaller dimenſions."

It is proper to obſerve, in the firſt place, that one of the moſt uſual cauſes of miſcarriage in this operation is a defect of the requiſite qualities in the retort employed. It is abſolutely neceſſary to have that veſſel made of the beſt earth, and ſo well made that it ſhall be capable of reſiſting the utmoſt violence of fire, continued for a very long time.

We ſhall, in the ſecond place, obſerve with M. Hellot, "that, before you ſet your retort in the furnace, it is proper to make an eſſay of your matter, to ſee if there be reaſon to hope for ſucceſs. For this purpoſe put about an ounce thereof into a ſmall crucible, and heat it till the veſſel be red. The mixture, after having ſmoked, ought to chop and crack without puffing up, or even riſing in the leaſt. From theſe cracks will iſſue undulated flames, white and bluiſh, darting upwards with rapidity. This is the firſt volatile phoſphorus, which occaſions all the danger of the operation. When theſe firſt flaſhes are over, increaſe the heat of your matter by laying a large live coal upon the crucible. You will then ſee the ſecond phoſphorus, like a luminous, ſteady vapour, of a colour inclining to violet, covering the whole ſurface of the matter: It continues for a very long time, and diffuſes a ſmell of garlick, which is the diſtinguiſhing odour of the phoſphorus you are ſeeking.

"When this luminous vapour is entirely gone, pour the red-hot matter out of the crucible upon an iron plate. If you do not find one drop of ſalt in fuſion, but that, on the contrary, the whole falls readily into powder, it is a proof that your matter was ſufficiently lixiviated, and that it contains no more fixed ſalt, or ſea-ſalt, if you will, than is requiſite. If you find on the plate a drop of ſalt coagulated, it ſhews that there is too much left in it, and that there is danger of your miſcarrying in the operation; becauſe the redundant ſalt would corrode and eat through the retort. In this caſe your matter muſt be waſhed again, and then ſufficiently dried."

The furnace muſt be ſo conſtructed, that within a narrow compaſs it may give a heat at leaſt equal to that of a glaſs-houſe furnace, or rather greater, eſpecially during the laſt ſeven or eight hours of the operation. M. Hellot, in his Memoir, gives an exact deſcription of ſuch a furnace.

"As certain accidents may happen in the courſe of the operation, ſome precautions are to be taken againſt them. For inſtance, if the ballon ſhould break while the phoſphorus is diſtilling, and any of it ſhould fall on combuſtible bodies, it would ſet them on fire, and probably burn the laboratory, becauſe it is not to be diſtinguiſhed without the greateſt difficulty. The furnace muſt therefore be erected under ſome vault, or upon a bed of brick-work, raiſed under ſome chimney that draws well: Nor muſt any furniture or utenſil of wood be left near it. If a little flaming phoſphorus ſhould fall on a man's legs or hands, in leſs than three minutes it would burn its way to the very bone. In ſuch a caſe nothing but urine will ſtop its progreſs.

"If the retort crack while the phoſphorus is diſtilling, there

there is an unſucceſsful end of your operation. It is eaſy to perceive this by the ſtink of garlick which you will ſmell about the furnace; and moreover, the flame that iſſues through the apertures of the reverberatory will be of a beautiful violet colour. The acid of ſea-ſalt always gives this colour to the flame of ſuch matters as are burnt along with it. But if the retort break before the phoſphorus hath made its appearance, its contents may be ſaved by throwing a number of cold bricks into the fire-place, and upon them a little water to quench the fire at once." All theſe uſeful obſervations we owe alſo to M. Hellot.

The phoſphorus here deſcribed was firſt diſcovered by a citizen of Hamburg named Brandt, who worked upon urine in ſearch of the philoſopher's ſtone. Afterwards two other ſkilful chemiſts, who knew nothing more of the proceſs than that phoſphorus was obtained from urine, or in general from the human body, likewiſe endeavoured to diſcover it; and each of them ſeparately did actually make the diſcovery. Theſe two chemiſts were Kunckel and Boyle.

The former perfected the diſcovery, and found out a method of making it in conſiderable quantities at a time; which occaſioned it to be called *Kunckel's phoſphorus*. The other, who was an Engliſh gentleman, had not time to bring his diſcovery to perfection, and contented himſelf with lodging a voucher of his having diſcovered it in the hands of the ſecretary of the Royal Society of London, who gave him a certificate thereof.

" Though Brandt, who had before this ſold his ſecret to a chemiſt named Krafft, ſold it afterwards to ſeveral other perſons, and even at a very low rate: and though Mr Boyle publiſhed the proceſs for making it; yet it is extremely probable that both of them kept in their own hands the maſter-key; I mean, *the particular management neceſſary to make the operation ſucceed:* For till Kunckel found it out, no other chemiſt ever made any conſiderable quantity thereof, except Mr Godfrey Hanwitz, an Engliſh chemiſt, to whom Mr Boyle revealed the whole myſtery.

" And thus it came to paſs, that, after Kunckel and Boyle died, M. Godfrey Hankwitz was the only chemiſt that could ſupply Europe therewith; on which account it is likewiſe very well known by the name of *Engliſh phoſphorus*."

Almoſt all the chemiſts conſider phoſphorus as a ſubſtance conſiſting of the acid of ſea-ſalt combined with the phlogiſton, in the ſame manner as ſulphur conſiſts of the vitriolic acid combined with the phlogiſton. This opinion is founded on the following principles.

Firſt, urine abounds with ſea-ſalt, and contains alſo a great deal of phlogiſton: now theſe are the ingredients of which they conjecture phoſporus to be compoſed.

Secondly, phoſphorus has many of the properties of ſulphur; ſuch as being ſoluble in oils; melting with a gentle heat; being very combuſtible; burning without any ſoot; giving a vivid and bluiſh flame; and laſtly, leaving an acid liquor when burnt: ſenſible proofs that it differs from ſulphur in nothing but the nature of its acid.

Thirdly, this acid of phoſphorus, being mixed with a ſolution of ſilver in ſpirit of nitre, precipitates the ſilver; and this precipitate is a true *luna cornea*, which appears to be more volatile even than the common ſort. This fact proves more inconteſtably that the acid of phoſphorus is of the ſame nature with that of ſea-ſalt.

Fourthly, M. Stahl obſerves, that if ſea-ſalt be caſt on live coals, they inſtantly burn with great activity; that they emit a vivid flame, and are much ſooner conſumed than if none of this ſalt had touched them; that ſea-ſalt in ſubſtance, which will bear the violence of fire a conſiderable time when fuſed in a crucible, without ſuſtaining any ſenſible diminution, yet evaporates very quickly, and is reduced to white flowers, by the immediate contact of burning coals; and laſtly, that the flame which riſes on this occaſion is of a blue colour inclining to violet, eſpecially if it be not thrown directly on the coals themſelves, but kept in fuſion amidſt burning coals, in a crucible ſo placed that the vapour of the ſalt may join with the inflamed phlogiſton as it riſes from the coals.

Theſe experiments of Mr Stahl's prove, that the phlogiſton acts upon the acid of ſea-ſalt, even while it is combined with its alkaline baſis. The flame that appears on this occaſion may be conſidered as an imperfect phoſphorus: and indeed its colour is exactly like that of phoſphorus.

All the facts above related evince, that the acid of phoſphorus is akin to that of ſea-ſalt; or rather, that it is the very ſame. But there are other facts which prove, that this acid undergoes ſome change at leaſt, ſome peculiar preparation, before it enters into the compoſition of a true phoſphorus; and that, when extricated therefrom by burning, it is not a pure acid of ſea-ſalt, but is ſtill adulterated with a mixture of ſome other ſubſtance, which makes it conſiderably different from that acid. For theſe obſervations we are obliged to M. Marggraff.

M. Marggraff hath alſo publiſhed a proceſs for making phoſphorus, and aſſures us, that by means thereof we may obtain in leſs time, with leſs heat, leſs trouble, and leſs expence, a greater quantity of phoſphorus than by any other method. His operation is this:

He takes two pounds of ſal ammoniac in powder, which he mixes accurately with four pounds of minium. This mixture he puts into a glaſs retort, and with a graduated fire draws off a very ſharp, volatile, urinous ſpirit.

We obſerved in Part I. that ſome metallic ſubſtances have the property of decompoſing ſal ammoniac, and ſeparating its volatile alkali. Minium, which is a calx of lead, is one of thoſe metallic ſubſtances. In this experiment it decompoſes the ſal ammoniac, and ſeparates its volatile alkali: what remains in the retort is a combination of the minium with the acid of ſal ammoniac, which is well known to be the ſame with the marine acid; and conſequently the reſidue of this operation is a ſort of *plumbum corneum*.

The quantity thereof is four pounds eight ounces. Of this he mixes three pounds with nine or ten pounds of urine, that has ſtood putrefying for two months, evaporated to the conſiſtence of honey. Theſe he mixes by

by little and little in an iron pan over the fire, ſtirring the mixture from time to time. Then he adds half a pound of charcoal duſt, and evaporates the matter, kept continually ſtirring, till the whole be brought to a black powder. He next diſtills the mixture in a glaſs retort with degrees of fire, which he raiſes towards the end ſo as to make the retort red-hot, in order to expel all the urinous ſpirit, ſuperfluous oil, and ammoniacal ſalt. The diſtillation being finiſhed, there remains nothing in the retort but a very friable *caput mortuum*.

This remainder he pulveriſes again, and throws a pinch of it on live coals to diſcover whether or no the matter be rightly prepared for yielding phoſphorus. If it be ſo, it preſently emits an arſenical odour, and a blue undulating flame, which paſſes over the ſurface of the coals like a wave.

Being thus aſſured of the ſucceſs of his operation, he puts one half of his matter, in three equal parts, into three ſmall earthen German retorts, capable of holding about eighteen ounces of water a-piece. Theſe three retorts, none of which is above three quarters full, he places together in one reverberatory furnace, built much like thoſe we have deſcribed, except that it is ſo conſtructed as to hold the three retorts diſpoſed in one line. To each retort he lutes a recipient ſomething more than half full of water, ordering the whole in ſuch a manner, that the noſes of his retorts almoſt touch the ſurface of the water.

He begins the diſtillation with warming the retorts ſlowly, for about an hour, by a gentle heat. When that time is elapſed he raiſes the fire gradually, ſo that in half an hour more the coals begin to touch the bottoms of the retorts. He continues throwing coals into the furnace by little and little, till they riſe half way the height of the retorts; and in this he employs another half hour. Laſtly, in the next half hour he raiſes the coals above the bowels of the retorts.

Then the phoſphorus begins to aſcend in clouds: on this he inſtantly increaſes the heat of the fire as much as poſſible, filling the ſurface quite up with coals, and making the retorts very red. This degree of fire cauſes the phoſphorus to diſtill in drops which fall to the bottom of the water. He keeps up this intenſe heat for an hour and half, at the end of which the operation is finiſhed; ſo that it laſts but four hours and a half in all: In the ſame manner he diſtills the ſecond moiety of his mixture in three other ſuch retorts.

He purifies and moulds his phoſphorus much in the ſame manner as M. Hellot does. From the quantity of ingredients above-mentioned, he obtains two ounces and a half fine cryſtalline moulded phoſphorus.

The acid of phoſphorus ſeems to be more fixed than any other: and therefore if you would ſeparate it by burning from the phlogiſton with which it is united, there is no occaſion for ſuch an apparatus of veſſels as is employed for obtaining the ſpirit of ſulphur. For this acid will remain at the bottom of the veſſel in which you burn your phoſphrus: indeed, if it be urged by the force of fire, its moſt ſubtile part evaporates, and the remainder appears in the form of a vitrified matter.

This acid effervesces with fixed and volatile alkalis, and therewith forms neutral ſalts; but very different from ſea-ſalt, and from ſal ammoniac. That which has a fixed alkali for its baſis does not crackle when thrown on burning coals; but ſwells and vitrifies like borax. That which has a volatile alkali for its baſis ſhoots into long pointed cryſtals; and, being urged by fire in a retort, lets go its volatile alkali, a vitrified matter remaining behind.

We ſhall conclude this article with an account of certain properties of phoſporus which have not yet been mentioned.

Phoſphorus diſſolves by lying expoſed to the air. What water cannot effect, ſays M. Hellot, or at leaſt requires eight or ten years to bring about, the moiſture of the air accompliſhes in ten or twelve days; whether it be that the phoſphorus takes fire in the air, and the inflammable part evaporating, almoſt entirely, leaves the acid of the phoſphorus naked, which like all other acids, when exceedingly concentrated, is very greedy of moiſture; or elſe that the moiſture of the air, being water divided into infinitely fine particles, is ſo ſubtile as to find its way through the pores of the phoſphorus, into which the groſſer particles of common water can by no means inſinuate themſelves.

Phoſphorus heated by the vicinity of fire, or by being any way rubbed, ſoon takes fire and burns fiercely. It is ſoluble in all oils, and in æther, giving to thoſe liquors the property of appearing luminous, when the bottle containing the ſolution is opened. Being boiled in water, it likewiſe communicates thereto this luminous quality.

The late Mr Groſſe obſerved, that phoſphorus being diſſolved in eſſential oils cryſtalliſes therein. Theſe cryſtals take fire in the air, either when thrown into a dry veſſel, or wrapt up in a piece of paper. If they be dipped in ſpirit of wine, and taken out immediately, they do not afterwards take fire in the air: they ſmoke a little, and for a very ſhort time, but hardly waſte at all. Though ſome of them were left in a ſpoon for a fortnight, they did not ſeem to have loſt any thing of their bulk: but when the ſpoon was warmed a little they took fire, juſt like common phoſphorus that had never been diſſolved and cryſtalliſed in an eſſential oil.

M. Marggraff, having put a dram of phoſphorus with an ounce of highly concentrated ſpirit of nitre into a glaſs retort, obſerved, that, without the help of fire, the acid diſſolved the phoſphorus; that part of the acid came over into the recipient which was luted to the retort; that at the ſame time the phoſphorus took fire, burnt furiouſly, and burſt the veſſels with exploſion. Nothing of this kind happens when any of the other acids, though concentrated, are applied to phoſphorus.

To decompoſe Sea-ſalt by means of the Vitriolic Acid. Glauber's Salt. The Purification and Concentration of Spirit of Salt.

Put the ſea-ſalt from which you mean to extract the acid into an unglazed earthen pipkin, and ſet it amidſt live coals. The ſalt will decrepitate, grow dry, and fall into a powder. Put this decrepitated ſalt into a tubulated glaſs retort, leaving two thirds thereof empty. Set the retort in a reverberating furnace; apply a receiver

ceiver like that ufed in diftilling the fmoking fpirit of nitre, and lute it on in the fame manner, or rather more exactly if poffible. Then through the hole in the upper convexity of the retort pour a quantity of highly concentrated oil of vitriol, equal in weight to about a third part of your falt, and immediately fhut the hole very clofe with a glafs ftopple, firft rubbed therein with emery fo as to fit it exactly.

As foon as the oil of vitriol touches the falt, the retort and receiver will be filled with abundance of white vapours; and foon after, without lighting any fire in the furnace, drops of a yellow liquor will diftil from the nofe of the retort. Let the diftillation proceed in this manner without fire, as long as you perceive any drops come; afterwards kindle a very fmall fire under the retort, and continue diftilling and raifing the fire by very flow degrees, and with great caution, to the end of the diftillation; which will be finifhed before you have occafion to make the retort red-hot. Unlute the veffels, and without delay pour the liquor, which is a very fmoking fpirit of falt, out of the receiver into a cryftal bottle, like that directed for the fmoking fpirit of nitre.

When the operation is finifhed, we find a white, faline mafs at the bottom of the retort as in a mould. If this mafs be diffolved in water, and the folution cryftallized, it yields a confiderable quantity of fea-falt that hath not been decompofed, and a neutral falt confifting of the vitriolic acid united with the alkaline bafis of that part which hath been decompofed. This neutral falt, which bears the name of *Glauber* its inventor, differs from vitriolated tartar, or the *Sal de duobus*, which remains after diftilling the nitrous acid, efpecially in that it is more fufible, more foluble in water, and hath its cryftals differently figured. But as in thefe two falts the acid is the fame, the differences that appear between them muft be attributed to the peculiar nature of the bafis of fea-falt.

Spirit of falt drawn by the procefs above defcribed is tainted with a fmall mixture of the vitriolic acid, carried up by the force of fire before it had time to combine with the alkali of the fea-falt; which happens likewife to the nitrous acid procured in the fame manner. If you defire to have it pure, and abfolutely free from the acid of vitriol, it muft be diftilled a fecond time from fea-falt, as the acid of nitre was before directed to be diftilled again from frefh nitre, in order to purify it from any vitriolic taint.

To decompofe Sea-falt by means of the Nitrous Acid. Aqua regis. *Quadrangular Nitre.*

Take dried fea-falt: bruife it to powder: put it into a glafs retort, leaving one half of the veffel empty. Pour upon it a third of its weight of good fpirit of nitre. Place your retort in the fand-bath of a reverberating furnace; put on the dome; lute to the retort a receiver having a fmall hole in it, and heat the veffels very flowly. There will come over into the receiver fome vapours, and an acid liquor. Increafe the fire gradually till nothing more rifes. Then unlute the veffels, and pour the liquor out of the receiver into a cryftal bottle, ftopped like others containing acid fpirits.

The nitrous acid hath a greater affinity than the marine acid with fixed alkalis. When therefore fpirit of nitre and fea-falt are mixed together, the fame confequences will follow as when the vitriolic acid is mixed with that falt; that is, the nitrous acid will, like the vitriolic, decompofe it, by diflodging its acid from its alkaline bafis, and affuming its place. But as the nitrous acid is confiderably weaker, and much lighter, than the vitriolic acid, a good deal of it rifes along with the acid of fea-falt during the operation. The liquor found in the receiver is therefore a true *aqua regis*.

If decrepitated falt, and a right fmoking fpirit of nitre, be employed in this procefs, the *aqua regis* obtained will be very ftrong.

The operation being finifhed, there is left in the retort a faline mafs, containing fea-falt not decompofed, and a new fpecies of nitre, which having for its bafis the alkali of fea-falt, that is, an alkali of a peculiar nature, differs from the common nitre, 1. In the figure of its cryftals; which are folids of four fides, formed like lozenges: 2. In that it cryftallizes with more difficulty, retains more water in its cryftals, attracts the moifture of the air, and diffolves in water with the fame circumftances as fea falt.

Of Borax.

To decompofe Borax by the means of Acids, and to feparate from it the Sedative Salt by Sublimation and by Cryftallifation.

Reduce to a fine powder the borax from which you intend to extract the fedative falt. Put this powder into a wide-necked glafs retort. Pour upon it an eighth part of its weight of common water, to moiften the powder; and then add concentrated oil of vitriol, to the weight of fomewhat more than a fourth part of the weight of the borax. Set the retort in a reverberatory, make a moderate fire at firft, and augment it gradually till the retort become red-hot.

A little phlegm will firft come over, and then, with the laft moifture that the heat expels, the fedative falt will rife; by which means fome of it will be diffolved in this laft phlegm, and pafs therewith into the receiver; but moft of it will adhere in the form of faline flowers to the fore-part of the neck of the retort, juft where it is clear of the groove of the furnace. There they collect into a heap, which the fucceeding flowers pufh infenfibly forward till they flightly ftop the paffage. Thofe which rife after the neck is thus ftopped ftick to the after part of it which is hot, vitrify in fome meafure, and form a circle of fufed falt. In this ftate the flowers of the fedative falt feem to iffue out of the circle, as from their bafis: They appear like very thin, light, fhining fcales, and muft be brufhed off with a feather.

At the bottom of the retort will be left a faline mafs: Diffolve this in a fufficient quantity of hot water; filter the folution, in order to free it from a brown earth which it depofites; fet the liquor to evaporate, and cryftals of fedative falt will form in it.

Though borax is of great ufe in many chemical operations, efpecially in the fufion of metals, as we fhall have

have occafion to fee, yet, till of late years, chemifts were quite ignorant of its nature, as they ftill are of its origin; concerning which we know nothing with certainty, but that it comes rough from the Eaft Indies, and is purified by the Dutch.

Of Operations on METALS.

Of GOLD.

To feparate Gold, by Amalgamation with Mercury, from the Earths and Stones with which it is found mixed.

PULVERISE the earths and ftones containing gold. Put the powder into a little wooden tray; dip this tray in water, gently fhaking it and its contents. The water will grow muddy, by taking up the earthy parts of the ore. Continue wafhing it in this manner till the water ceafe to appear turbid. Upon the ore thus wafhed pour ftrong vinegar, having firft diffolved therein, by the help of heat, about a tenth part of its weight of alum. The powder muft be quite drenched and covered with this liquor, and fo left to ftand for twice twenty-four hours.

Decant the vinegar, and wafh your powder with warm water, till the laft that comes off hath no tafte: then dry it, and put it into an iron mortar, with four times its weight of quick-filver: triturate the whole with a heavy wooden peftle, till all the powder be of a blackifh colour: then pour in a little water, and continue rubbing for fome time longer. More earthy and heterogeneous particles will be feparated from the metalline parts by means of this water, which will look dirty: it muft then be decanted, and more fair water added. Repeat this feveral times; then dry what remains in the mortar with a fponge, and by the help of a gentle heat; you will find it an almalgam of the mercury with the gold.

Put this almalgam into a chamoy bag: tie a knot on its neck, and fqueeze it hard between your fingers, over fome wide-mouthed veffel; there will iffue through the pores of the leather numberlefs little jets of mercury, forming a fort of fhower, that will collect into large globules in the veffel placed underneath. When you can force out no more mercury by this means, open the bag, and in it you will find the amalgam freed from the fuperfluous mercury; the gold retaining only about as much thereof as nearly equals itfelf in weight.

Put this amalgam into a glafs retort: fet this retort in the fand-bath of a reverberating furnace; cover it quite over with fand; apply a glafs receiver half full of of water, fo that the nofe of the retort may be under the water. The receiver need not be luted to the retort. Give a gradual heat, and raife the fire till drops of the fublimed mercury appear in the neck of the retort, and fall into the water with a hiffing noife. If you hear any noife in the retort, flacken your fire a little. Laftly, when you obferve, that, though you raife the fire ftill higher than before, nothing more will come over, take out your retort, break it, and there you will find the gold, which muft be melted in a crucible with borax.

To diffolve Gold in Aqua regis, *and by that means to feparate it from Silver.*

TAKE gold that is perfectly pure, or alloyed with filver only. Reduce it to little thin plates, by hammering it on an anvil. If it be not fufficiently tough, neal it till it be red in a moderate, clear fire, quite free from fmoking coals, and then let it cool gradually, which will reftore its ductility.

When the plates are thin enough, make them red-hot once more, and cut them into fmall bits with a pair of fheers. Put thefe bits into a tall, narrow-mouthed cucurbit, and pour on them twice their weight of good *aqua regis*, made of one part fal-ammoniac, or fpirit of falt, and four parts fpirit of nitre. Set the cucurbit in a fand-bath moderately heated, ftopping its orifice flightly with a paper coffin, to prevent any dirt from falling in. The *aqua regis* will prefently begin to fmoke. Round the little bits of gold will be formed an infinite number of fmall bubbles, which will rife to the furface of the liqnor. The gold will totally diffolve, if it be pure, and the folution will be of a beautiful yellow colour: if the gold be alloyed with a fmall quantity of filver, the latter will remain at the bottom of the veffel in the form of a white powder. If the gold be alloyed with much filver, when the gold is diffolved the filver will retain the form of the little metalline plates put into the veffel.

When the diffolution is completed, gently pour off the liquor into another low, wide-mouthed, glafs cucurbit, taking care that none of the filver, which lies at the bottom in the form of a powder efcape with the liquor. On this powder of filver pour as much frefh *aqua regis* as will cover it entirely; and repeat this till you are fure that nothing more can be taken up by it. Laftly, having decanted the *aqua regis* from the filver, wafh the filver with a little fpirit of falt weakened with water, and add this fpirit of falt to the *aqua regis* in which your gold is diffolved. Then to the body containing thefe liquors fit a head and a receiver, and diftill with a gentle heat, till the matter contained in the cucurbit become dry.

Mix together equal parts of common brimftone, and a very ftrong fixed alkali; for inftance, nitre fixed by charcoal. Put them in a crucible, and melt the mixture, ftirring it from time to time with a fmall rod. There is no occafion to make the fire very brifk, becaufe the fulphur facilitates the fufion of the fixed alkali. Some fulphureous vapours will rife from the crucible: the two fubftances will mix intimately together, and form a reddifh compound. Then throw into the crucible fome little pieces of gold beat into thin plates, fo that the whole do not exceed in weight one third part of the liver of fulphur: raife the fire a little. As foon as the liver of fulphur is perfectly melted, it will begin to diffolve the gold with ebullition; and will even emit fome flafhes of fire. In the fpace of a few minutes the gold will be entirely diffolved, efpecially if it was cut and flatted into fmall thin leaves.

The procefs here delivered is taken from M. Stahl. The defign of his inquiries was to difcover how Mofes could burn the golden calf, which the Ifraelites had fet up and worfhipped while he was on the mount; how he could afterwards reduce that calf to powder, throw it into the water which the people ufed, and make all who had apoftatized drink thereof, as related in the book of Exodus,

Exodus; and he concludes, that Mofes muft have performed this operation by means of liver of fulphur.

To feparate Gold from all other metallic Subftances by means of Antimony.

Having put the gold you intend to purify into a crucible, fet it in a melting furnace, cover it, and make the gold flow. When the metal is in fufion, caft upon it, by a little at a time, twice its weight of pure crude antimony in powder, and after each projection cover the crucible again immediately: this done keep the matter in fufion for a few minutes. When you perceive that the metallic mixture is perfectly melted, and that its furface begins to fparkle, pour it out into a hollow iron cone, previoufly heated, and fmeared on the infide with tallow. Immediately ftrike with a hammer the floor on which the cone ftands; and when all is cold, or at leaft fufficiently fixed, invert the cone and ftrike it: the whole metallic mafs will fall out, and the under part thereof, which was at the point of the cone, will be a regulus more or lefs yellow as the gold was more or lefs pure. On ftriking the metallic mafs, the regulus will freely part from the fulphureous cruft at top.

Return this regulus into the crucible, and melt it. Lefs fire will do now than was required before. Add the fame quantity of antimony, and proceed as at firft. Repeat the fame operation a third time, if your gold be very impure.

Then put your regulus into a good crucible, much larger than is neceffary to hold it. Set your crucible in a melting furnace, and heat the matter but juft enough to make it flow, with a fmooth, brilliant furface. When you find it thus conditioned, point towards it the nofe of a long-fnouted pair of bellows, and therewith keep gently and conftantly blowing. There will arife from the crucible a confiderable fmoke, which will abate greatly when you ceafe to blow, and increafe as foon as you begin again. You muft raife the fire gradually as you approach towards the end of the operation. If the furface of the metal lofe its brilliant polifh, and feem covered with a hard cruft, it is a fign the fire is too weak; in which cafe it muft be increafed, till the furface recover its fhining appearance. At laft, when no more fmoke rifes, and the furface of the gold looks neat and greenifh, caft on it, by little and little, fome pulverized nitre, or a mixture of nitre and borax. The matter will fwell up. Continue thus adding more nitre gradually, till no commotion is thereby produced in the crucible; and then let the whole cool. If you find, when the gold is cold, that it is not tough enough, melt it over again; when it begins to melt caft it in the fame falts as before; and repeat this till it be perfectly ductile.

To feparate Silver from its Ore, by means of Scorification with Lead.

Beat to powder in an iron mortar the ore from which you mean to feparate the filver, having firft roafted it well in order to free it from all the fulphur and arfenic that it may contain. Weigh it exactly: then weigh out by itfelf eight times as much granulated lead. Put one half of this lead into a teft, and fpread it equally thereon: upon this lead lay your ore, and cover it quite over with the remaining half of the lead.

Place the teft thus loaded under the further end of the muffle in a cupelling furnace. Light your fire, and increafe it by degrees. If you look through one of the apertures in the door of the furnace, you will perceive the ore, covered with calcined lead, fwim upon the melted lead. Prefently afterwards it will grow foft, melt, and be thrown towards the fides of the veffel, the furface of the lead appearing in the midft thereof bright and fhining like a luminous difc: the lead will then begin to boil, and emit fumes. As foon as this happens, the fire muft be a little checked, fo that the ebullition of the lead may almoft entirely ceafe for about a quarter of an hour. After this it muft be excited to the degree it was at before, fo that the lead may begin again to boil and fmoke. Its fhinning furface will gradually leffen, and be covered with *fcoriæ*. Stir the whole with an iron hook, and draw in towards the middle what you obferve towards the fides of the veffel; to the end that, if any part of the ore fhould ftill remain undiffolved by the lead, it may be mixed therewith.

When you perceive that the matter is in perfect fufion, that the greateft part of what fticks to the iron hook, when you dip it in the melted matter, feparates from it again, and drops back into the veffel; and that the extremity of this inftrument, when grown cold, appears varnifhed over with a thin, fmooth, fhining cruft; you may look on thefe as marks that the bufinefs is done; and the more uniform and evenly the colour of the cruft is, the more perfect may you judge the fcorification to be.

Matters being brought to this pafs, take the teft with a pair of tongs from under the muffle, and pour its whole contents into an iron cone, firft heated and greafed with tallow. This whole operation lafts about three quarters of an hour. When all is cold, the blow of a hammer will part the regulus from the fcoria; and as it is not poffible, how perfect foever the fcorification be, to avoid leaving a little lead containing filver in the fcoria, it is proper to pulverife this fcoria, and feparate therefrom whatever extends under the hammer, in order to add it to the regulus.

The refining of Silver by the Cupel.

Take a cupel capable of containing one third more matter than you have to put into it: fet it under the muffle of a furnace like that defcribed in our theoretical elements, as peculiarly appropriated to this fort of operation. Fill the furnace with charcoal; light it; make the cupel red-hot, and keep it fo till all its moifture be evaporated; that is, for about a good quarter of an hour, if the cupel be made wholly of the afhes of burnt bones; and for a whole hour, if there be any wafhed wood-afh in its compofition.

Reduce the regulus which remained after the preceding operation to little thin plates, flatting them with a fmall hammer, and feparating them carefully from all the adherent fcoria. Wrap thefe in a bit of paper, and with a fmall pair of tongs put them gently into the cupel. When the paper is confumed, the regulus will foon melt,

and

and the ſcoria, which will be gradually produced by the lead as it turns to litharge, will be driven to the ſides of the cupel, and immediately abſorbed thereby. At the ſame time the cupel will aſſume a yellow, brown, or blackiſh colour, according to the quantity and nature of the ſcoria imbibed by it.

When you ſee the matter in the cupel in a violent ebullition, and emitting much ſmoke, lower the fire by the methods formerly preſcribed. Keep up ſuch a degree of heat only that the ſmoke which aſcends from the matter may not riſe very high, and that you may be able to diſtinguiſh the colour which the cupel acquires from the ſcoria.

Increaſe the fire by degrees, as more and more litharge is formed and abſorbed. If the regulus examined by this aſſay contain no ſilver, you will ſee it turn wholly into ſcoria, and at laſt diſappear. When it contains ſilver, and the quantity of lead is much diminiſhed, you will perceive little vivid iriſes, or beautiful rain-bow colours, ſhooting ſwiftly along its ſurface, and croſſing each other in many different directions. At laſt, when all the lead is deſtroyed, the thin dark ſkin, that is continually protruded by the lead while it is turning into litharge, and which hitherto covered the ſilver, ſuddenly diſappears; and, if at this moment the fire happen not to be ſtrong enough to keep the ſilver in fuſion, the ſurface of that metal will at once dart out a dazzling ſplendor; but, if the fire be ſtrong enough to keep the ſilver in fuſion, though freed from all mixture of lead, this change of colour, which is called its *fulguration*, will not be ſo perceptible, and the ſilver will appear like a bead of fire.

Theſe phenomena ſhew that the operation is finiſhed. But the cupel muſt ſtill be left a minute or two under the muffle, and then drawn ſlowly out with the iron hook towards the door of the furnace. When the ſilver is ſo cooled as to be but moderately red, you may take the cupel from under the muffle with your little tongs, and in the middle of its cavity you will find an exceeding white bead of ſilver, the lower part whereof will be unequal, and full of little pits.

To purify Silver by Nitre.

Granulate the ſilver you intend to purify, or reduce it to thin plates; put it into a good crucible; add thereto a fourth part in weight of very dry pulveriſed nitre, mixed with half the weight of the nitre of calcined wine-lees, and about a ſixth part of the ſame weight of common glaſs in powder. Cover this crucible with another crucible inverted; which muſt be of ſuch a ſize that its mouth may enter a little way into that of the lower one, and have its bottom pierced with a hole of about two lines in diameter. Lute the two crucibles together with clay and Windſor-loam. When the lute is dry, place the crucibles in a melting furnace. Fill the furnace with charcoal, taking care however that they do not riſe above the upper crucible.

Kindle the fire, and make your veſſels of a middling red heat. When they are ſo, take up with the tongs a live coal, and hold it over the hole of the upper crucible. If you immediately perceive a vivid ſplendor round the coal, and at the ſame time hear a gentle hiſſing noiſe, it is a ſign that the fire is of a proper ſtrength; and it muſt be kept up at the ſame degree till this phenomenon ceaſe.

Then increaſe the fire to the degree requiſite to keep pure ſilver in fuſion; and immediately take your veſſels out of the furnace. You will find the ſilver at the bottom of the lower crucible covered with a maſs of alkaline ſcoria of a greeniſh colour. If the metal be not rendered perfectly pure and ductile by this operation, it muſt be repeated a ſecond time.

To diſſolve Silver in Aqua Fortis, *and thereby ſeparate it from every other metalline Subſtance.*

The ſilver you intend to diſſolve being beaten into thin plates, put it into a glaſs cucurbit; pour on it twice its weight of good precipitated *aqua fortis*; cover the cucurbit with a paper, and ſet it on a ſand-bath moderately heated. The *aqua fortis* will begin to diſſolve the ſilver as ſoon as it comes to be a little warm. Red vapours will riſe; and from the upper ſurfaces of the ſilver there will ſeem to iſſue ſtreams of little bubbles, aſcending to the top of the liquor, between which and the ſilver they will form, as it were, a number of fine chains: This is a ſign that the diſſolution proceeds duly, and that the degree of heat is ſuch as it ought to be. If the liquor appear to boil and be agitated, a great many red vapours riſing at the ſame time, it is a ſign that the heat is too great, and ſhould be leſſened till it be reduced to the proper degree indicated above: having obtained that, keep it equally up till no more bubbles or red vapours appear.

If your ſilver be alloyed with gold, the gold will be found, when the diſſolution is finiſhed, at the bottom of the veſſel in the form of a powder. The ſolution muſt now be decanted while it is yet warm: on the powder pour half as much freſh *aqua fortis* as before, and make it boil; again decant this ſecond *aqua fortis*, and repeat the ſame a third time; then with fair water waſh the remaining powder well: It will be of a brown colour inclining to red.

To ſeparate Silver from the Nitrous Acid by Diſtillation. Cryſtals of Silver. The Infernal Stone.

Into a large, low, glaſs body, put the ſolution of ſilver from which you intend to ſeparate the ſilver by diſtillation. To this body fit a tubulated head provided with its ſtopple. Set this alembic in a ſand-bath, ſo that the body may be almoſt covered with ſand: apply a receiver, and diſtill with a moderate heat, ſo that the drops may ſucceed each other at the diſtance of ſome ſeconds. If the receiver grow very hot, check the fire. When red vapours begin to appear, pour into the alembic, through the hole in its head, a freſh quantity of your ſolution of ſilver, firſt made very hot. Continue diſtilling in this manner, and repeating the addition of freſh liquor, till all your ſolution be put into the alembic. When you have no more freſh ſolution to put in, and when, the phlegm being all come over, red vapours begin again to appear, convey into the alembic half a dram or a dram of tallow, and diſtill to drineſs; which

being

being done, increaſe your fire ſo as to make the veſſel containing the ſand-bath red-hot. In the alembic you will find a calx of ſilver, which muſt be melted in a crucible with ſome ſoap and calcined wine-lees.

If the diſtillation be ſtopped when part of the phlegm is drawn off, and the liquor be then ſuffered to cool, many cryſtals will ſhoot therein, which are a neutral ſalt conſtituted of the nitrous acid and ſilver. If the diſtillation be carried further, and ſtopped when near its concluſion, the liquor being then ſuffered to cool will wholly coagulate into a blackiſh maſs called the *infernal ſtone*.

To ſeparate Silver from the nitrous Acid by Precipitation. Luna Cornea. Luna Cornea *reduced.*

INTO your ſolution of ſilver pour about a fourth part in weight of ſpirit of ſalt, ſolution of ſea-ſalt, or ſolution of ſal ammoniac. The liquor will inſtantly become turbid and milky. Add twice or thrice its weight of fair water, and let it ſtand ſome ſome hours to ſettle. It will depoſite a white powder. Decant the clear liquor, and on the precipitate pour freſh *aqua fortis*, or ſpirit of ſalt, and warm the whole on a ſand-bath with a gentle heat for ſome time. Pour off this ſecond liquor, and boil your precipitate in pure water, ſhifting it ſeveral times, till the precipitate and the water be both quite inſipid. Filter the whole, and dry the precipitate, which will be a *luna cornea*, and muſt be reduced in the following manner.

Smear the inſide of a good crucible well with ſoap. Put your *luna cornea* into it; cover it with half its weight of ſalt of tartar, thoroughly dried and pulveriſed; preſs the whole hard down; pour thereon as much oil, or melted tallow, as the powder is capable of imbibing; ſet the crucible thus charged, and cloſe covered, in a melting furnace, and, for the firſt quartet of an hour, kindle no more fire than is neceſſary to make the crucible moderately red; after that raiſe it ſo as to melt the ſilver and the ſalt, throwing into the crucible from time to time little bits of tallow. When it ceaſes to ſmoke, let the whole cool; or pour it into a hollow iron cone, warmed and tallowed.

To diſſolve Silver, and ſeparate it from Gold, by Cementation.

MIX thoroughly together fine brick-duſt four parts, vitriol calcined to redneſs one part, and ſea-ſalt or nitre one part. Moiſten this powder with a little water. With this cement cover the bottom of a crucible half an inch thick; on this firſt bed lay a thin plate of the maſs of gold and ſilver you intend to cement, and which you muſt previouſly take care to beat into ſuch thin plates. Cover this plate with a ſecond layer of cement, of the ſame thickneſs as the former; on this ſecond bed lay another plate of your metal; cover it in like manner with cement; and ſo proceed till the crucible be filled to within half an inch of its brim. Fill up the remaining ſpace with cement, and cloſe the crucible with a cover, luted with a paſte made of Windſor-loam and water: Set your crucible thus charged in a furnace, whoſe fire-place is deep enough to let it be entirely furrounded with coals, quite up to its mouth. Light ſome coals in the furnace, taking care not to make the fire very briſk at firſt; increaſe it by degrees, but only ſo far as to make the crucible moderately red; keep up the fire in this degree for eighteen or twenty hours: Then let the fire go out; open the crucible when it is cold, and ſeparate the cement from your plates of gold. Boil the gold repeatedly in fair water, till the water come off quite inſipid.

Of COPPER.

To ſeparate Copper from its Ore.

BEAT your copper ore to a fine powder, having firſt freed it as accurately as poſſible, by waſhing and roaſting, from all ſtony, earthy, ſulphureous, and arſenical parts. Mix your ore thus pulveriſed with thrice its weight of the black flux; put the mixture into a crucible; cover it with common ſalt to the thickneſs of half an inch, and preſs the whole down with your finger. With all this the crucible muſt be but half full. Set it in a melting furnace; kindle the fire by degrees, and raiſe it inſenſibly till you hear the ſea-ſalt crackle. When the decrepitation is over, make the crucible moderately red-hot for half a quarter of an hour. Then give a conſiderable degree of heat, exciting the fire with a pair of good perpetual bellows, ſo that the crucible may become very red-hot, and be perfectly ignited. Keep the fire up to this degree for about a quarter of an hour; then take out the crucible, and with a hammer ſtrike a few blows on the floor on which you ſet it. Break it when cold. If the operation hath been rightly and ſucceſsfully performed, you will find at the bottom of the veſſel a hard regulus, of a bright yellow colour, and ſemi-malleable; and over it a ſcoria of a yellowiſh brown colour, hard, and ſhining, from which you may ſeparate the regulus with a hammer.

To purify black Copper, and render it malleable.

BREAK into ſmall bits the black copper you intend to purify; mix therewith a third part in weight of granulated lead, and put the whole into a cupel ſet under the muffle in a cupelling furnace, and previouſly heated quite red. As ſoon as the metals are in the cupel raiſe the fire conſiderably, making uſe, if it be needful, of a pair of perpetual bellows, to melt the copper ſpeedily. When it is thoroughly melted, lower the fire a little, and continue it juſt high enough to keep the metalline maſs in perfect fuſion. The melted matter will then boil, and throw up ſome ſcoriæ, which will be abſorbed by the cupel.

When moſt of the lead is conſumed, raiſe the fire again till the face of the copper become bright and ſhining, thereby ſhewing that all its alloy is ſeparated. As ſoon as your copper comes to this ſtate, cover it with charcoal duſt conveyed into the cupel with an iron laddle: Then take the cupel out of the furnace, and let it cool.

To deprive Copper of its Phlogiſton by Calcination.

PUT your copper in filings into a teſt, and ſet it under the muffle of a cupelling furnace; light the fire, and keep up ſuch a degree of heat as may make the whole quite

quite red, but not enough to melt the copper. The surface of the copper will gradually lose its metalline splendor, and put on the appearance of a reddish earth. From time to time stir the filings with a little rod of copper or iron, and leave your metal exposed to the same degree of fire till it be always calcined.

To resuscitate the Calx of Copper, and reduce it to Copper, by restoring its Phlogiston.

Mix the calx of copper with thrice as much of the black flux; put the mixture into a good crucible, so as to fill two thirds thereof, and over it put a layer of sea-salt a finger thick. Cover the crucible, and set it in a melting furnace; heat it gradually, and keep it moderately red till the decrepitation of the sea-salt be over. Then raise the fire considerably by means of a good pair of perpetual bellows; satisfy yourself that the matter is in perfect fusion, by dipping into the crucible an iron wire; continue the fire in this degree for half a quarter of an hour. When the crucible is cold, you will find at its bottom a button of very fine copper, which will easily separate from the saline scoria at top.

To dissolve Copper in the Mineral Acids.

On a sand-bath, in a very gentle heat, set a matras containing some copper filings; pour on them twice their weight of oil of vitriol. That acid will presently attack the copper. Vapours will rise, and issue out of the neck of the matras. A vast number of bubbles will ascend from the surface of the metal to the top of the liquor, and the liquor will acquire a beautiful blue colour. When the copper is dissolved, put in a little and a little more, till you perceive the acid no longer acts upon it. Then decant the liquor, and let it stand quiet in a cool place. In a short time great numbers of beautiful blue crystals will shoot in it. These crystals are called *vitriol of copper*, or *blue vitriol*. They dissolve easily in water.

Of Iron.

To separate Iron from its Ore.

Pound into a coarse powder the martial stones or earths out of which you design to extract the iron: Roast this powder in a test under the muffle for some minutes, and let your fire be brisk. Then let it cool, beat it very fine, and roast it a second time, keeping it under the muffle till it emit no more smell.

Then mix with this powder a flux composed of three parts of nitre fixed with tartar, one part of fusile glass, and half a part of borax and charcoal-dust. The dose of this reducing flux must be thrice the weight of the ore.

Put this mixture into a good crucible; cover it with about half a finger thick of sea-salt; over the crucible put its cover, and lute it on with Windsor-loam made into a paste with water. Having thus prepared your crucible, set it in a melting furnace, which you must fill up with charcoal. Light the fire, and let it kindle by gentle degrees, till the crucible become red-hot. When the decrepitation of the sea-salt is over, raise your fire to the highest by the blast of a pair of perpetual bellows, or rather several. Keep up this intense degree of heat for three quarters of an hour, or a whole hour, taking care that during all this time the furnace be kept constantly filling up with fresh coals as the former consume. Then take your crucible out of the furnace; strike the pavement on which you set it several times with a hammer, and let it stand to cool: Break it, and you will find therein a regulus of iron covered with slag.

In smelting-houses iron ore is fused amidst charcoal, the phlogiston of which combines with the martial earth, and gives it the metalline form. The iron thus melted runs down to the bottom of the furnace, from whence it is let out into large moulds, in which it takes the shape of oblong blocks, called *pigs* of iron. This iron is still very impure, and quite unmalleable. Its want of ductility after the first melting arises partly from hence, that, notwithstanding the previous roasting which the ore underwent, there still remains, after this first fusion, a considerable quantity of sulphur or arsenic combined with the metal.

A certain quantity of quick lime, or of stones that will burn to lime, is frequently mixed with iron ore on putting it into the smelting furnace. The lime being an absorbent earth, very apt to unite with sulphur and arsenic, is of use to separate those minerals from the iron.

It is also of use to mix some such matters with the ore, when the stones or earths which naturally accompany it are very fusible; for, as the iron is of difficult fusion, it may happen that the earthy matters mixed with the iron shall melt as easily as the metal, or perhaps more easily. In such a case there is no separation of the earthy from the metalline part, both of which melt and precipitate together promiscuously: Now quick-lime, being extremely refractory, serves on this occasion to check the melting of those matters which are too fusible.

Yet quick-lime, notwithstanding its refractory quality, may sometimes be of use as a flux for iron: This is the case when the ore happens to be combined with substances which, being united with lime, render it fusible: Such are all arsenical matters, and even some earthy matters, which, being combined with quick-lime, make a fusible compound.

When the ore of an iron mine is found difficult to reduce, it is usually neglected even though it be rich; because iron being very common, people chuse to work those mines only whose ores are smelted with the most ease, and require the least consumption of wood.

Yet refractory ores are not to be altogether rejected, when another iron ore of a different quality is found near them. For it often happens, that two several iron ores, which being worked separately are very difficult to manage, and yield at last but bad iron, become very tractable, and yield excellent iron, when smelted together: And accordingly such mixtures are often made at iron-works.

The iron obtained from ores by the first fusion may be divided into two sorts. The one, when cold, resists the hammer, doth not easily break, and is in some measure extensible on the anvil; but if struck with a hammer, when red-hot, flies into many pieces: This sort of iron hath always

always a mixture of fulphur in it. The other fort, on the contrary, is brittle when cold, but fomewhat ductile when red-hot. This iron is not fulphurated, is naturally of a good quality, and its brittlenefs arifes from its metalline parts not being fufficiently compacted together.

Iron abounds fo much, and is fo univerfally diffufed through the earth, that it is difficult to find a body in which there is none at all: And this hath led feveral chemifts into the error of thinking, that they had tranfmuted into iron feveral forts of earths in which they fufpected no iron, by combining them with an inflammable matter; whereas, in fact, all they did was to give the metalline form to a true martial earth which happened to be mixed with other earths.

To render Pig-iron and brittle Iron malleable.

INTO an earthen veffel widening upwards, put fome charcoal-duft, and thereon lay the pig-iron which you propofe to render ductile; cover it all over with a quantity of charcoal; excite the fire violently with a pair, or more, of perpetual bellows till the iron melt. If it do not readily flow and form a great deal of flag on its furface, add fome flux, fuch as a very fufible fand.

When the matter is in fufion, keep ftirring it from time to time, that all the parts thereof may be equally acted on by the air and the fire. On the furface of the melted iron *fcoriæ* will be formed, which muft be taken off as they appear. At the fame time you will fee a great many fparkles darted up from the furface of the metal, which will form a fort of fiery fhower. By degrees, as the iron grows purer, the number of thefe fparkles diminifhes, though they never vanifh entirely. When but few fparkles appear, remove the coals which cover the iron, and let the flag run out of the veffel; whereupon the metal will grow folid in a moment. Take it out while it is ftill red-hot, and give it a few ftrokes with a hammer, to try if it be ductile. If it be not yet malleable, repeat the operation a fecond time, in the fame manner as before. Laftly, when it is thus fufficiently purified by the fire, work it for a long time on the anvil, extending it different ways, and making it red-hot as often as there is occafion. Iron thus brought to the neceffary degree of ductility, fo as to yield to the hammer, and fuffer itfelf to be extended every way, either hot or cold, without breaking to bits, or even cracking in the leaft, is very good and very pure If it cannot be brought to this degree by the method here prefcribed, it is a proof, that the ore from which this iron was extracted, ought to be mixed with other ores; but it frequently requires a great number of trials to obtain an exact knowledge of the quality and proportion of thofe other ores with which it is to be mixed.

To convert Iron into Steel.

TAKE fmall bars of the beft iron; that is, of fuch as is malleable both hot and cold; fet them on their ends in a cylindrical earthen veffel, whofe depth is equal to the length of the bars, and in fuch a manner that they may be an inch diftant from each other, and from the fides of the crucible. Fill the veffel with a cement compounded of two parts of charcoal, on part of bones burnt in a clofe veffel till they become very black, and one half part of the afhes of green wood; having firft pulverifed and thoroughly mixed the whole together. Take care to lift up the iron bars a little, to the end that the cement may cover the bottom of the veffel, and fo that there be about the depth of half an inch thereof under every bar: Cover the crucible and lute on the cover.

Set the crucible thus prepared in a furnace, fo contrived, that the crucible may be furrounded with coals from top to bottom: For eight or ten hours keep up fuch a degree of fire that the veffel may be moderately red; after this take it out of the furnace; plunge your little iron bars into cold water; and you will find them converted into fteel.

The principal difference between iron and fteel confifts in this, that the latter is combined with a greater quantity of phlogifton than the former.

It appears by this experiment, that, to make iron unite with an inflammable matter, it is neceffary it fhould be in fufion; it is fufficient that it be fo red-hot as to be opened and foftened by the fire.

Every kind of charcoal is fit to be an ingredient in the compofition of the cement employed to make fteel, provided it contain no vitriolic acid. However, it hath been obferved, that animal coals produce a fpeedier effect than others: for which reafon it is proper to mix fomething of that kind with charcoal-duft, as above directed.

The following figns fhew that the operation hath fucceeded, and that the iron is changed into good fteel.

This metal being quenched in cold water as propofed above, acquires fuch an extraordinary degree of hardnefs, that it will by no means yield to any impreffion of the file or hammer, and will fooner break in pieces than ftretch upon the anvil. And here it is proper to obferve, that the hardnefs of fteel varies with the manner in which it is quenched. The general rule is, that the hotter the fteel is when quenched, and the colder the water is in which you quench it, the harder it becomes. It may be deprived of the temper thus acquired, by making it red-hot, and letting it cool flowly; for it is thereby foftened, rendered malleable, and the file will bite upon it. For this reafon the artifans who work in fteel begin with untempering it, that they may with more eafe fhape it into the tool they intend to make. They afterwards new-temper the tool when finifhed. and by this fecond temper the fteel recovers the fame degree of hardnefs it had acquired by the firft temper.

The colour of fteel is not fo white as that of iron, but darker, and the grains. facets, or fibres, which appear on breaking it, are finer than thofe obferved in iron.

If the bars of iron thus cemented, in order to convert them into fteel, be too thick, or not kept long enough in cementation, they will not be turned into fteel throughout their whole thicknefs: their furfaces only will be fteel to a certain depth, and the centre will be mere iron; becaufe the phlogifton will not have thoroughly penetrated them. On breaking a bar of this fort, the difference in colour and grain between the fteel and the iron is very vifible.

It is eafy to deprive fteel of the fuperabundant quantity of

of phlogiſton which conſtitutes it ſteel, and thereby reduce it to iron. For this purpoſe it need only be kept red-hot for ſome time, obſerving that no matter approach it all the while that is capable of refunding to it the phlogiſton which the fire carries off. The ſame end is ſtill ſooner obtained by cementing it with meagre hungry matters, capable of abſorbing the phlogiſton; ſuch as bones calcined to whiteneſs, and cretaceous earths.

The Calcination of Iron. Sundry Saffrons of Mars.

Take filings of iron, what quantity you pleaſe; put them into a broad unglazed earthen veſſel, ſet under the muffle of a cupelling furnace: make it red-hot; ſtir the filings frequently; and keep up the ſame degree of fire till the iron be wholly turned into a red powder.

Iron eaſily loſes its phlogiſton by the action of fire. The calx that remains after its calcination is exceeding red; which makes this be thought the natural colour of the earth of that metal. It hath accordingly been obſerved, that all the earths and ſtones which either are naturally red, or acquire that colour by calcination, are ferruginous.

The yellowiſh red colour which every calx of iron hath, in whatever manner it be prepared, hath procured the name of *crocus*, or *ſaffron*, to every preparation of this kind. That made in the manner above directed is called in medicine *crocus martis aſtringens*.

The ruſt produced on the ſurface of iron, is a ſort of calx of iron made by the way of diſſolution. The moiſture of the air acts upon the metal, diſſolves it, and robs it of ſome of its phlogiſton. This ruſt is called in medicine *crocus martis aperiens*; becauſe it is thought that the ſaline parts, by means whereof the humidity diſſolves the iron, remain united with the metal after its diſſolution, and give it an aperitive virtue. The apothecaries prepare this ſort of ſaffron of mars by expoſing iron filings to the dew till they be turned entirely to ruſt; which is then called *ſaffron of mars by dew*.

Another ſaffron of mars is alſo prepared in a much ſhorter manner, by mixing filings of iron with pulveriſed ſulphur, and moiſtening the mixture, which after ſome time ferments and grows hot. It is then ſet on the fire; the ſulphur burns away, and the maſs is kept ſtirring till it become a red matter. This ſaffron is nothing but iron diſſolved by the acid of ſulphur, which is known to be of the ſame nature with that of vitriol; and conſequently this ſaffron of mars is no way different from vitriol calcined to redneſs.

Iron diſſolved by the mineral Acids.

Put any mineral acid whatever into a matras with ſome water; ſet the matras on a ſand-bath gently heated; drop into the veſſel ſome filings of iron: the phenomena which uſually accompany metalline diſſolutions will immediately appear. Add more filings, till you obſerve the acid hath loſt all ſenſible action upon them: then remove your matras from the ſand-bath; you will find in it a ſolution of iron.

Of Tin.

To extract Tin from its Ore.

Break your tin ore into a coarſe powder, and by waſhing carefully, ſeparate from it all the heterogeneous matters and ores of a different kind that may be mixed therewith. Then dry it, and roaſt it in a ſtrong degree of fire, till no more arſenical vapour riſe from it. When the ore is roaſted, reduce it to a fine powder, and mix it thoroughly with twice its weight of the black flux well dried, a fourth part of its weight of clean iron filings, together with as much borax and pitch: put the mixture into a crucible; over all put ſea-ſalt to the thickneſs of four fingers, and cover the crucible cloſe.

Set the crucible thus prepared in a melting furnace: apply at firſt a moderate and ſlow degree of fire, till the flame of the pitch, which will eſcape through the joint of the cover, diſappear entirely. Then ſuddenly raiſe your fire, and urge it with rapidity to the degree neceſſary for melting the whole mixture. As ſoon as the whole is in fuſion, take the crucible out of the furnace, and ſeparate the regulus from the ſcoria.

All tin ores contain a conſiderable quantity of arſenic, and no ſulphur at all, or at moſt very little. Hence, though tin be the lighteſt of all metals, its ore is nevertheleſs much heavier than any other; arſenic being much heavier than ſulphur, of which the ores of every other kind always contain a pretty large proportion. This ore is moreover very hard, and is not brought to a fine powder with ſo much eaſe as the reſt.

Theſe properties of tin ore furniſh us with the means of ſeparating it eaſily by lotion, not only from earthy and ſtony parts, but even from the other ores which may be mixed with it. And this is of the greater advantage on two accounts, *viz.* becauſe tin cannot endure, without the deſtruction of a great part thereof, the degree of fire neceſſary to ſcorify the refractory matters which accompany its ore; and again, becauſe this metal unites ſo eaſily with iron and copper, the ores of which are pretty commonly blended with tin ore, that after the reduction it would be found adulterated with a mixture of theſe two metals, if they were not ſeparated from it before the fuſion.

Into an unvarniſhed earthen diſh put the quantity of tin you intend to calcine; melt it, and keep ſtirring it from time to time. Its ſurface will be covered with a greyiſh white powder: Continue the calcination till all your tin be converted into ſuch a powder, which is the *calx of tin*.

The diſſolution of Tin by Acids.

Put into a glaſs veſſel what quantity you pleaſe of fine tin cut into little bits. Pour on it thrice as much *aqua regis*, compounded of two parts *aqua fortis* weakened with an equal quantity of very pure water, and one part ſpirit of ſalt. An ebullition will ariſe, and the tin will be very rapidly diſſolved; eſpecially if the quantities of metal and of *aqua regis* be conſiderable.

To

To extract Lead from its Ore.

Having roafted your lead-ore, reduce it to a fine powder; mix it with twice its weight of the black flux, and one fourth of its weight of clean iron filings and borax; put the whole into a crucible capable of containing at leaft thrice as much; over all put fea-falt four fingers thick; cover the crucible; lute the juncture; dry the whole with a gentle heat, and fet it in a melting furnace.

Make the crucible moderately red: yon will hear the fea-falt decrepitate, and after the decrepitation a fmall hiffing in the crucible. Keep up the fame degree of fire till that be over.

Then throw in as many coals as are neceffary to complete the operation entirely, and raife the fire fuddenly, fo as to bring the whole mixture into perfect fufion. Keep up this degree of fire for a quarter of an hour, which is time fufficient for the precipitation of the regulus.

When the operation is finifhed, which may be known by the quietnefs of the matter in the crucible, and by a bright vivid flame that will rife from it, take the crucible out of the furnace, and feparate the regulus from the fcoria.

To feparate Lead from Copper.

With luting earth and charcoal duft make a flat veffel, widening upwards, and large enough to contain your metalline mafs. Set it fhelving downwards from the back towards the fore-part; and in the fore-part, at the bottom, make a little gutter communicating with another veffel of the fame nature, placed near the former and a little lower. Let the mouth of the gutter withinfide the upper veffel be narrowed, by means of a fmall iron plate fixed acrofs it, while the loam is yet foft; fo as to leave a very fmall appertnre in the lower part of this canal fufficient to difcharge the lead as it melts. Dry the whole by placing lighted coals round it.

When this apparatus is dry, put your mixed mafs of copper and lead into the upper veffel: both in that, and in the other veffel, light a very gentle fire of wood or charcoal, fo as not to exceed the degree of heat neceffary to melt lead. In fuch a degree of heat the lead contained in the mixed mafs will melt, and you will fee it run out of the upper veffel into the lower; at the bottom of which it will unite into a regulus. When in this degree of heat no more lead flows, increafe the fire a little, fo as to make the veffel moderately red.

When no more will run, collect the lead contained in the lower veffel. Melt it over again in an iron ladle, with a degree of fire fufficient to make the ladle red; throw into it a little tallow or pitch, and while it burns keep ftirring the metal, in order to reduce any part of it that may be calcined. Remove the pellicle or thin cruft which will form on the furface; fqueeze out all the lead it contains, and then put it to the mafs of copper left in the upper veffel. Check the fire, and in the fame manner take off a fecond fkin that will form on the furface of the lead. Laftly, when the metal is ready to fix, take off the fkin that will then appear on it. The lead remaining after this will be very pure, and free from all alloy of copper.

With regard to the copper itfelf, you will find it in the upper veffel covered with a thin coat of lead, and if the lead mixed with it was in the proportion of a fourth or a fifth part only, and the fire applied was gentle and flow, it will retain nearly the fame form after the operation that the mixed mafs had before.

The Calcination of Lead.

Take what quantity of lead you pleafe; melt it in one or more unglazed earthen pans: a dark grey powder will be found on its furface. Keep ftirring the metal inceffantly till it be wholly converted into fuch a powder, which is the *calx of lead.*

In the calcination of all metals, and particularly in this of lead, there appears a fingular phenomenon which is not eafily accounted for. It is this: though thefe matters lofe a great deal of their fubftance, either by the diffipation of their phlogifton, or becaufe fome of the metal perhaps exhales in vapours, yet, when the calcination is over, their calxes are found to be encreafed in weight, and this increafe is very confiderable. An hundred pounds of lead, for example, converted into minium, which is nothing but a calx of lead brought to a red colour by continuing the calcination, are found to gain ten pounds weight; fo that for an hundred pounds of lead we have one hundred and ten pounds of minium: a prodigious and almoft incredible augmentation, if it be confidered that, far from adding any thing to the lead, we have on the contrary diffipated part of it.

To prepare Glafs of Lead.

Take two parts of litharge, and one part of pure cryftalline fand; mingle them together as exactly as poffible, adding a little nitre and fea-falt: put this mixture into a crucible of the moft folid and moft compact earth. Shut the crucible with a cover that may perfectly clofe it.

Set the crucible thus prepared in a melting furnace; fill the furnace with coals; light the fire gradually, fo that the whole may be flowly heated: Then raife the fire fo as to make the crucible very red, and bring the matter it contains into fufion; keep it thus melted for a quarter of an hour.

Then take the crucible out of the furnace, and break it: in the bottom thereof you will moft commonly find a fmall button of lead, and over it a tranfparent glafs of a yellow colour nearly refembling that of amber. Separate this glafs from the little button of metal, and from the faline matters which you will find above it.

Lead diffolved by the Nitrous Acid.

Put into a matras fome *aqua fortis* precipitated like that ufed to diffolve filver; weaken it by mixing therewith an equal quantity of common water; fet the matras in a hot fand-bath; throw into it, little by little, fmall bits of lead, till you fee that no more will diffolve. *Aqua fortis* thus lowered will diffolve about a fourth of its weight of lead.

There is gradually formed upon the lead, as it diffolves, firft a grey powder, and afterwards a white cruft, which

which at laſt hinder the ſolvent from acting on the remaining part of the metal; and therefore the liquor ſhould be made to boil, and the veſſel ſhould be ſhaken to remove thoſe impediments, by which means all the lead will be diſſolved.

Of MERCURY.

To extract Mercury from its Ore, or to revivify it from Cinabar.

PULVERIZE the cinabar from which you would extract the mercury; with this powder mix an equal part of clean iron filings; put the mixture into a retort of glaſs or iron, leaving at leaſt one third part thereof empty. Set the retort thus prepared in a ſand-bath, ſo that its body may be quite buried in the ſand, and its neck decline conſiderably downwards: fit on a receiver half filled with water, and let the noſe of the retort enter about half an inch into the water.

Heat the veſſel ſo as to make the retort moderately red. The mercury will riſe in vapours, which will condenſe into little drops, and fall into the water in the receiver. When you ſee that nothing more comes over with this degree of heat, increaſe it, in order to raiſe what mercury may ſtill be left. When all the mercury is thus brought over, take off the receiver, pour out the water contained in it, and collect the mercury.

Mercury is never mineralized in the bowels of the earth by any thing but ſulphur: with which it forms a compound of a browniſh red colour, known by the name of *Cinabar*.

The oldeſt and richeſt mine of mercury is that of Almaden in Spain. It is a ſingular property of that mine, that though the mercury found in it is combined with ſulphur, and in the form of cinabar, yet no additament is required to procure the ſeparation of theſe two; the earthy and ſtony matter, with which the particles of the ore are incorporated, being itſelf an excellent abſorbent of ſulphur.

In the quick-ſilver works carried on at this mine they make no uſe of retorts. They place lumps of the ore on an iron grate, which ſtands immediately over the furnace. The furnaces which ſerve for this operation are cloſed at the top by a ſort of dome, behind which ſtands the ſhaft of a chimney that communicates with the fire-place, and gives vent to the ſmoke. Theſe furnaces have in their fore-ſide ſixteen apertures, to each of which is luted an aludel in a horizontal poſition, communicating with a long row of other aludels placed likewiſe in an horizontal direction; which aludels ſo connected together form one long pipe or canal, the further end whereof opens into a chamber deſtined to receive and condenſe all the mercurial vapours. Theſe rows of aludels are ſupported from end to end by a terraſs, which runs from the body of the building, wherein the furnaces are erected, to that where the chambers are built that perform the office of receivers.

This a very ingenious contrivance, and ſaves much labour, expence, and trouble, that would be unavoidable if retorts were employed.

That part of the furnace which contains the lumps of ore, ſerves for the body of the retort; the row of aludels for its neck; and the little chambers in which theſe canals terminate are actual receivers. The terraſs of of communication, which reaches from the one building to the other, is formed of two inclined planes, the lower edges of which, meeting in the middle of the terraſs, riſe from thence inſenſibly; the one quite to the building where the furnaces are, and the other to that which forms the recipient chambers. By this means, when any mercury eſcapes through the joints of the aludels, it naturally runs down along theſe inclined planes, and ſo is collected in the middle of the terraſs, where the inferior ſides of the planes meeting together form a ſort of canal, out of which it is eaſily taken up.

To give Mercury, by the action of Fire, the appearance of a Metalline Calx.

Put mercury into ſeveral little glaſs matraſſes with long and narrow necks. Stop the matraſſes with a little paper, to prevent any dirt from falling into them. Set them all in one ſand-bath, ſo that they may be ſurrounded with ſand as high as two thirds of their length. Apply the ſtrongeſt degree of heat that mercury can bear without ſubliming: continue this heat without interruption, till all the mercury be turned to a red powder. The operation laſts about three months.

Mercury thus converted to a red powder is known in chemiſtry and medicine by the name of *mercury precipitated per ſe*.

To diſſolve Mercury in the Vitriolic Acid. Turbith mineral.

Put mercury into a glaſs retort, and pour on it thrice its weight of good oil of vitriol. Set the retort in a ſand-bath; fit on a recipient; warm the bath by degrees till the liquor juſt ſimmer. With this heat the mercury will begin to diſſolve. Continue the fire in this degree till all the mercury be diſſolved.

The vitriolic acid diſſolves mercury pretty well: but for this purpoſe the acid muſt be very hot, or even boil; and then too it is a very long time before the diſſolution is completed. We have directed the operation to be performed in a retort; becauſe this ſolution is uſually employed to make another preparation called *turbith mineral*, which requires that as much as poſſible of the acid ſolvent be abſtracted by diſtillation. Having therefore diſſolved your mercury in the vitriolic acid, if you will now prepare the turbith, you muſt, by continuing to heat the retort, drive over all the liquor into the receiver, and diſtill till nothing remains but a white powdery matter: then break the retort; pulveriſe its contents in a glaſs mortar, and thereon pour common water, which will immediately turn the white matter of a lemon-colour; waſh this yellow matter in five or ſix warm waters, and it will be what is called in medicine *turbith mineral*; that is, a combination of the vitriolic acid with mercury, five or ſix grains whereof is a violent purgative, and alſo an emetic; qualities which it poſſeſſes in

common with the vegetable turbith, whofe name it hath therefore taken.

To combine Mercury with fulphur. Æthiops Mineral.

Mix a dram of fulphur with three drams of quickfilver, by triturating the whole in a glafs mortar with a glafs peftle. By degrees, as you triturate, the mercury will difappear, and the matter will acquire a black colour. Continue the triture till you cannot perceive the leaft particle of running mercury. The black matter you will then have in the mortar is known in medicine by the name of *æthiops mineral.* An æthiops may alfo be made by fire in the following manner.

In a fhallow unglazed earthen pan melt one part of flowers of fulphur: add three parts of running mercury, making it fall into the pan in the form of fmall rain, by fqueezing it through chamoy leather. Keep ftirring the mixture with the fhank of a tobacco-pipe all the while the mercury is falling: you will fee the matter grow thick and acquire a black colour. When the whole is thoroughly mixed, fet fire to it with a match, and let as much of the fulphur burn away as will flame.

To fublime the combination of Mercury and Sulphur into Cinabar.

Grind to powder æthiops mineral prepared by fire. Put it into a cucurbit; fit thereto a head; place it in a fand-bath, and begin with applying fuch a degree of heat as is requifite to fublime fulphur. A black matter will rife, and adhere to the fides of the veffel. When nothing more will rife with this degree of heat, raife the fire fo as to make the fand and the bottom of the cucurbit red; and then the remaining matter will fublime in the form of a brownifh red mafs, which is true *cinabar.*

To diffolve Mercury in the Nitrous acid. Sundry Mercurial Precipitates.

Put into a matras the quantity of mercury you intend to diffolve: pour on it an equal quantity of good fpirit of nitre, and fet the matras in a fand-bath moderately heated. The mercury will diffolve with the phenomena that ufually attend the diffolutions of metals in this acid. When the diffolution is completed, let the liquor cool. You will know that the acid is perfectly faturated, if there remain at the bottom of the veffel, notwithftanding the heat, a little globule of mercury that will not diffolve.

Mercury diffolves in the nitrous acid with much more facility, and in much greater quantity, than in the vitriolic; fo that it is not neceffary, on this occafion, to make the liquor boil. This folution when cold yields cryftals, which are a nitrous mercurial falt. If you defire to have a clear limpid folution of mercury, you muft employ an *aqua fortis* that is not tainted with vitriolic or marine acid: for, the affinity of thefe two acids with mercury being greater than that of the nitrous acid, they precipitate it in the form of a white powder, when they are mixed with the folvent.

Mercury thus precipitated in a white powder, out of a folution thereof in the fpirit of nitre, is ufed in medicine. To obtain this precipitate, which is known by the name of the *white precipitate*, fea-falt, diffolved in water, together with a little fal ammoniac is ufed; and the precipitate is wafhed feveral times in pure water, without which precaution it would be corrofive, on account of the great quantity of the marine acid which it would contain.

The preparation known by the name of *red precipitate*, is alfo obtained from our folution of mercury in fpirit of nitre. It is made by abftracting all the moifture of the folution, either by diftillation in a retort, or by evaporation in a glafs bafon fet on a fand-bath. When it begins to grow dry, it appears like a white ponderous mafs. Then the fire is made ftrong enough to drive off almoft all the nitrous acid, which, being now concentrated, rifes in the form of red vapours. If thefe vapours be catched in a receiver, they condenfe into a liquor, which is a very ftrong and vaftly fmoking fpirit of nitre.

By degrees, as the nitrous acid is forced up by the fire, the mercurial mafs lofes its white colour, and becomes firft yellow, and at laft very red. When it is become entirely of this laft colour, the operation is finifhed. The red mafs remaining is a mercury that contains but very little acid, in comparifon of what it did while it was white: and indeed the firft white mafs is fuch a violent corrofive, that it cannot be ufed in medicine; whereas, when it is become red, it makes an excellent efcharotic, which thofe who know how to ufe it properly apply with very great fuccefs, particularly to venereal ulcers.

To combine Mercury with the Acid of Sea-falt. Corrofive Sublimate.

Evaporate a folution of mercury in the nitrous acid till there remain only a white powder, as mentioned in our obfervations on the preceding procefs. With this powder mix as much green vitriol calcined to whitenefs, and decrepitated fea-falt, as there was mercury in the folution. Triturate the whole carefully in a glafs mortar. Put this mixture into a matras, fo that two thirds thereof may remain empty, having firft cut off the neck to half its length; or inftead thereof you may ufe an apothecary's phial. Set your veffel in a fand-bath, and put fand round it as high as the contents reach. Apply a moderate fire at firft, and raife it by flow degrees. Vapours will begin to afcend. Continue the fire in the fame degree till they ceafe. Then ftop the mouth of the veffel with paper, and increafe the fire till the bottom of the fand-bath be red-hot. With this degree of heat a fublimate will rife, and adhere to the infide and upper part of the veffel, in the form of white, femi-tranfparent cryftals. Keep up the fire to the fame degree till nothing more fublimes. Then let the veffel cool; break it, and take out what is fublimed, which is *corrofive fublimate.*

Sweet Sublimate.

Take four parts of corrofive fublimate; pulverife it in a glafs or marble mortar; add by little and little three parts of mercury revivified from cinabar; triturate the whole carefully, till the mercury be perfectly killed, fo that

that no globule thereof can be perceived. The matter will then be grey. Put this powder into an apothecary's phial, or into a matras, whofe neck is not above four or five inches long, leaving two thirds thereof empty. Set the veffel in a fand-bath, and put fand round it to one third of its height. Apply a moderate fire at firft; and afterwards raife it gradually till you perceive that the mixture fublimes. Keep it up to this degree till nothing more will rife, and then break the veffel. Reject, as ufelefs, a fmall quantity of earth which you will find at the bottom; feparate alfo what adheres to the neck of the veffel, and carefully collect the matter in the middle, which will be white. Pulverife it; fublime it a fecond time, in the fame manner as before; and in the fame manner feparate the earthy matter left at the bottom of the veffel, and what you find fublimed into the neck. Pulverife, and fublime a third time, the white matter you laft found in the middle. The white matter of this third fublimation is the *fweet fublimate*, called alfo *aquila alba*.

The Panacea of Mercury.

Pulverise fome fweet fublimate, and fublime it in the fame manner as you did thrice before. Repeat this nine times. After thefe fublimations it will make no impreffion on the tongue. Then pour on it aromatic fpirit of wine, and fet the whole in digeftion for eight days. After that decant the fpirit of wine, and dry what remains, which is the *panacea of mercury*.

Of Antimony.

To feparate Antimony from its Ore by Fufion.

Having drilled fome fmall holes, of about two lines diameter, in the bottom of a crucible, put into it your antimonial ore broken into little bits, about the fize of a hazel nut; lute on its cover; fet the crucible thus prepared in the mouth of another crucible, and clofe the joints with lute.

At the diftance of half a foot from this compound veffel place bricks all round, fo as to form a furnace; the fides of which muft rife as high as the brim of the uppermoft crucible.

Let the bottom of this furnace be filled with afhes, up to the top of the lower crucible, and the reft of the furnace with lighted coals. Blow the fire, if it be neceffary, with bellows, till the upper crucible become red. Keep it up in this degree for about a quarter of an hour. Then take your veffels out of the furnace, and you will find the antimony collected in the bottom of the lower crucible, having run through the holes of the upper one.

The common Regulus of Antimony.

Reduce crude antimony to powder. Mix it with three fourths of its weight of white tartar, and half its weight of refined falt-petre, both pulverifed. Into a large crucible, made red-hot in the fire, throw a fpoonfull of your mixture, and cover it. There will be a very confiderable detonation. When it is over, throw in a fecond fpoonfull of your mixture, and cover the crucible as before: this will produce a fecond detonation. Go on thus, till you have thrown in all your mixture.

When the whole has thus fulminated, increafe the fire fo as to bring the matter into fufion; that being done, take the crucible out of the furnace, and immediately pour its contents into an iron cone heated and greafed with tallow. Strike the floor and the cone fome gentle blows with a hammer, to make the regulus precipitate; and when the matter is fixed and cold, invert the cone, and turn it out. You will fee it confift of two diftinct fubftances; the uppermoft of which is a faline fcoria, and the undermoft the reguline part. Strike this mafs a blow with a hammer, in the place where thefe fubftances join, and you will by this means feparate the fcoria from the regulus; the latter of which will have the form of a metallic cone, on whofe bafe you will obferve the fignature of a bright ftar.

Regulus of Antimony precipitated by Metals.

Put one part of fmall iron nails into a crucible, and fet it amidft burning coals, in a melting furnace. When the iron is thoroughly red-hot, and begins to grow white, add thereto little by little, and at feveral times, two parts of crude antimony in powder. The antimony will immediately flow and unite with the iron. When the antimony is entirely melted, add thereto, at feveral times, the fourth of its weight of pulverifed nitre: a detonation will enfue, and the whole mixture will be in fufion.

After you have kept the matter in this condition for fome minutes, pour it into an iron cone, firft heated and tallowed. Strike the fides of the cone with a hammer, that the regulus may fall to the bottom; and, when all is cold, feparate it from the fcoria by a blow with a hammer. Melt this firft regulus again in another crucible, adding a fourth part of its weight of crude antimony. Keep the crucible clofe fhut, and give no more heat than is neceffary to melt the matter. When it is in perfect fufion, add to it at feveral times, as you did before, the fixth part of its weight of pulverifed nitre; and, in half a quarter of an hour after this, pour the whole into a cone as you did the firft time.

Laftly, Melt your regulus over again a third or even a fourth time, always adding a little nitre, which will detonate as before. If after all thefe fufions you pour the regulus into an iron cone, you will find it very beautiful, and the ftar well formed: it will be covered with a femi-tranfparent, lemon-coloured fcoria. This fcoria is extremely acrid and cauftic.

The Calcination of Antimony.

Take an unglazed earthen veffel, wider at top than at bottom; put into it two or three ounces of crude antimony finely pulverifed. Set this veffel over a weak charcoal-fire, and increafe the heat till you fee the antimony begin to fmoke a little. Continue the fire in this degree, and keep inceffantly ftirring the antimony with the fhank of a tobacco-pipe all the while it is upon the fire.

The powder of antimony, which, before calcination, was of a brilliant colour inclining to black, will become dull,

dull, and look like an earth. When it comes to have this appearance, raise your fire till the vessel be red-hot, and keep it up in this degree till the matter cease entirely to smoke.

Calx of Antimony reduced to a Regulus.

Mix the calx of antimony, which you intend to reduce, with an equal quantity of black soap. This mixture will make a thin paste. Put it little by little into a crucible, previously made red-hot amidst live coals. Thus let the soap burn, till it cease to emit an oily smoke. Then cover the crucible; make the fire strong enough to melt the matter, and you will hear it effervesce and boil. When this noise is over, let the crucible cool, and then break it: you will find in it a beautiful scoria, marked with circles of several colours; and under that a button of regulus, which is not yet quite pure, and must be purified in the following manner.

Pound this regulus, and mix it with half its weight of an antimonial calx as perfectly desulphurated as possible. Put it into a crucible, and cover it: melt the whole, so that the surface of the melted matter may be smooth and uniform. Let the crucible cool, and then break it: you will find in it a beautiful button of very pure regulus, covered with a scoria, having the appearance of an opaque glass, or a kind of greyish enamel, moulded on the finely radiated surface of the regulus.

Antimony calcined with Nitre. Liver of Antimony.

Pulverise and mix perfectly together equal parts of nitre and antimony: put the mixture into an iron mortar, and cover it with a tile, which however must not shut it quite close. With a live coal set fire to the matter in the mortar, and immediately withdraw it. The mixture will flame, with great detonation; which being over, and the mortar cooled, invert it, and strike its bottom to make all the matter fall out. Then, by a blow with a hammer, separate the scoria from the shining part, which is the *liver of antimony*.

Another Calcination of Antimony with Nitre. Diaphoretic Antimony.

Mix one part of antimony with three parts of nitre; project this mixture by spoonfulls into a crucible kept red hot in a furnace. Each projection will be attended with a detonation. Continue doing this till you have used all your mixture: then raise the fire, and keep it up for two hours; after which throw your matter into a pan full of hot water. Let it lie steeping in water kept hot for a whole day. Then pour off the liquor: wash the white powder you find at bottom in warm water; and repeat the ablutions till the powder become insipid. Dry it, and you have *diaphoretic antimony*.

Calx of Antimony vitrified.

Take any quantity you please of calx of antimony, made without addition; put it into a good crucible, which set in a melting furnace: kindle the fire gradually, and leave the crucible uncovered at the beginning.

A quarter of an hour after the matter is red-hot, cover the crucible, and excite the fire vigorously till the calx melt. You may know when it is thoroughly melted, by dipping into the crucible an iron wire, to the end of which a little knob of glass will adhere, if the matter be in perfect fusion. Keep it in fusion for a quarter of an hour, or rather longer if your crucible can bear it. Then take it out of the furnace, and immediately pour out the melted matter on a smooth stone, made very hot for the purpose: it will presently fix into a yellow glass.

Kermes Mineral.

Break any quantity you will of Hungarian antimony into little bits: put it into a good earthen coffee-pot: pour on it twice its weight of rain-water, and a fourth part of its weight of well filtered liquor of nitre fixed by charcoal. Boil the whole briskly for two hours, and then filter the liquor. As it cools it will acquire a red colour, grow turbid, and leave a red powder on the filter.

Return your antimony into the coffee-pot. Pour on it as much rain-water as before, and three fourths of the former quantity of the liquor of fixed nitre. Boil it again for two hours, and then filter the liquor. It will again deposite a red sediment. Return your antimony into the coffee pot: pour on it the same quantity of rain-water, and half the first quantity of the liquor of fixed nitre. Boil it again for two hours, and filter the liquor as formerly. Wash all these sediments with warm water, till they become insipid; then dry them, and you have the *kermes mineral*.

Regulus of Antimony dissolved in the Mineral Acids.

Compound an *aqua regis* by mixing together four measures of spirit of nitre, and one measure of spirit of salt: on a sand-bath moderately heated place a matras, into which pour sixteen times as much of this *aqua regis* as you have regulus to dissolve. Break your regulus in little bits; and throw them successively one after another into the matras, observing not to add a new one till that put in before is entirely dissolved: continue this till your regulus be all used. By degrees, as the dissolution advances, the liquor will acquire a beautiful golden colour; which however will insensibly disappear, as the white fumes that continually ascend from it evaporate.

Regulus of Antimony combined with the Acid of Sea-salt. Butter of Antimony. Cinabar of Antimony.

Pulverise and mix thoroughly six parts of regulus of antimony, and sixteen parts of corrosive sublimate. Put this mixture into a glass retort that hath a wide short neck, and let one half of its body at least be left empty. Set it in a reverberatory furnace, and having fitted a recipient thereto and luted the joint, make a very small fire at first to heat it slowly. Increase it afterwards by degrees, till you see a liquor ascend from the retort that grows thick as it cools. Keep up the fire to this degree as long as you see any of this matter come over.

When no more arises with this degree of fire, unlute your vessels, take off the receiver, and in its place substitute another filled with water. Then increase your fire by degrees till the retort be red hot. Some running

ning mercury will fall into the water, which you may dry and keep for ufe; it being very pure.

Soon after mixing the regulus with the corrofive fublimate, the matter fometimes grows confiderably hot: This is occafioned by the marine acid's beginning to act on the reguline part, and to defert its mercury.

The butter of antimony rifes with a very moderate heat; becaufe the acid of fea-falt hath the property of volatilizing, and carrying up along with it, the metallic fubftances with which it is combined: And for this reafon a very gentle heat only is required at the beginning of the operation.

It is abfolutely neceffary that the neck of the retort be wide and fhort: for otherwife, if the butter of antimony fhould fix and be accumulated therein, it might ftop up the paffage entirely, and occafion the burfting of the veffels. By this operation we obtain eight parts and three quarters of fine butter of antimony, and ten parts of running mercury; there being left in the retort one part and a half of a rarefied matter, black, white, and red. This is probably the moft earthy and moft impure part of the regulus of antimony.

If crude antimony, inftead of regulus of antimony, be mixed with corrofive fublimate, a butter of antimony will be obtained in the fame manner; but, inftead of having a running mercury after the butter, you will find a cinabar fublimed into the neck and upper concavity of the retort.

The reafon of this difference is eafily conceived: for, when the regulus is ufed, the mercury being deferted by its acid, finds no other fubftance to unite with, and fo rifes in the form of quick-filver; but when crude antimony is employed inftead of its regulus, as the reguline part thereof cannot combine with the acid without quitting its fulphur, fo this fulphur, being at liberty, unites with the mercury, which is fo likewife, and therewith forms a cinabar; which from its origin is named *cinabar of antimony*.

Butter of Antimony decompounded by means of Water only. The Pulvis Algaroth, *or* Mercurius Vitæ.

Melt with a gentle heat as much butter of antimony as you pleafe. When it is melted, pour it into a large quantity of warm water. The water will immediately grow turbid, but whitifh, and let fall a great quantity of white powder. When all the precipitate is fettled, decant the water: pour on frefh warm water; and having thus edulcorated it by feveral ablutions, dry it, and you have the *pulvis Algaroth*, or *mercurius vitæ*.

Bezoar Mineral.

Melt butter of antimony over warm afhes, and put it into a phial or matras. Gradually pour on it good fpirit of nitre, till the matter be entirely diffolved. This ufually requires as much fpirit of nitre as there is butter of antimony. During the diffolution fumes will rife, which muft be carefully avoided. Pour your folution, which will be clear and of a reddifh colour, into a glafs cucurbit, or a pan of ftone-ware; fet it in a fand-bath, and evaporate to drynefs with a moderate heat. There will be left a white mafs, weighing a fourth part lefs than the whole quantity ufed, both of butter and the fpirit of nitre. Let it cool, and again pour on it as much fpirit of nitre as you ufed the firft time. Place the veffel again in the fand-bath, and evaporate the moifture as before. You will have a white mafs that hath neither gained nor loft in weight. On this pour, for the third time, the fame quantity of fpirit of nitre as you did the firft time. Again evaporate the moifture to perfect drynefs: then increafe your fire, and calcine the matter for half an hour. You will have left a dry, friable, light, white matter, of an agreeable acid tafte; which will fall into a coarfe powder, and muft be kept in a phial carefully ftopt. This is Bezoar mineral: it is neither cauftic nor emetic, and has only a fudorific virtue. It obtained the name it bears, becaufe, like the animal bezoar, it was imagined to have the property of refifting poifon.

Flowers of Antimony.

Take an unglazed earthen pot, having an aperture in its fide, with a ftopple to fhut it clofe. Set this pot in a furnace, the cavity whereof it may fit as exactly as poffible; and fill up with lute the fpace, if any, left between the veffel and the furnace. Over this veffel fix three aludels with a blind-head at the top; and light a fire in the furnace under the pot.

When the bottom of the pot is thoroughly red, throw into the lateral aperture a fmall fpoonful of powdered antimony. Stir the matter immediately with an iron fpatula made a little bending, in order to fpread it over the bottom of the veffel, and then ftop the hole. The flowers will rife and adhere to the infides of the aludels. Keep up the fire fo that the bottom of the pot may always continue red; and, when nothing more fublimes, put in a like quantity of antimony, and operate as before. In this manner go on fubliming your antimony, till you have as many flowers as you want. Then let the fire go out; and when the veffels are cold, unlute them. You will find flowers adhering all round the infides of the aludels and the head, which you may collect with a feather.

Regulus of Antimony converted into Flowers.

Pulverise your regulus of antimony: put the powder into an unglazed earthen port: three or four fingers breadth above the powder, fit into the pot a little cover, made of the fame earth and having a fmall hole in its middle, fo that it may with eafe be placed in the pot and taken out when there is occafion: cover the mouth of the pot with a common lid; fet it in a furnace, and kindle a fire under it fufficient to make the bottom of the pot red and to melt the regulus. When it hath been thus kept in fufion for about an hour, let the fire go out and the whole cool. Then remove the two covers. You will find adhering to the furface of the regulus, which will be in a mafs at the bottom of the pot, white flowers refembling fnow, intermixed with beautiful, brilliant, filver coloured needles. Take them out, and you will find them make about one part in fixty-two of the whole regulus employed.

Put the covers again in their places, and proceed in the fame manner as before: When the veffels are cold,

cold, you will find half as many more flowers as you got the firſt time.

Proceed thus till you have converted all your regulus into flowers. This will require a cōnſiderable number of ſublimations, which, as you advance, will always yield you a greater portion of flowers; reſpect, however, being had to the quantity of regulus remaining in the pot.

Of Bismuth.

To extract Biſmuth from its Ore.

Break the ore of biſmuth into ſmall pieces, and therewith fill a crucible either of earth or iron. Set the the crucible in a furnace, and light ſuch a fire that the bits of ore may become moderately red. Stir the ore from time to time; and if you perceive it crackle and fly, keep the crucible covered. At the bottom you will find a button of biſmuth.

Biſmuth diſſolved by Acids. Magiſtery of Biſmuth. Sympathetic Ink.

Into a matras put biſmuth broken into little bits: pour on it, by little and little, twice as much *aqua fortis*. This acid will attack the ſemi-metal briſkly, and diſſolve it entirely, with heat, effervescence, vapours, and puffing up. The ſolution will be clear and limpid.

If you would have a magiſtery of biſmuth beautifully white, you muſt perform the diſſolution with an *aqua fortis* that is not tainted with any mixture of the vitriolic acid; for this gives the precipitate a dirty white colour, inclining to grey.

Biſmuth may alſo be precipitated by the means of fixed or volatile alkalis; but the precipitate is not of ſo fine a white as when procured by the means of pure water only.

A ſolution of biſmuth prepared with the proper quantity of *aqua fortis*, that is, with two parts of the acid to one of the ſemi metal, coaleſces into little cryſtals almoſt as ſoon as made.

Aqua fortis not only acts on biſmuth when ſeparated from its ore, and reduced to a regulus, but attacks it even in its ore, and likewiſe diſſolves at the ſame time ſome portion of the ore itſelf. With this ſolution of the ore of biſmuth Mr Hellot makes a very curious ſympathetic ink, differing from all that were known before.

Mr Hellot prepares the liquor in the following manner: "He bruiſes the ore of biſmuth to a coarſe powder. On two ounces of this powder he pours a mixture of five ounces of common water with five ounces of *aqua fortis*. He does not heat the veſſel till the firſt ebullitions are over. He then ſets it in a gentle ſand-heat, and lets it digeſt there till he ſees no more air-bubbles riſe. When none appear in this heat, he increaſes it ſo as to make the ſolvent boil ſlightly for a full quarter of an hour. It takes up a tincture nearly of the colour of brown beer. The ore that gives the *aqua fortis* this colour is the beſt. He then lets the ſolution cool, laying the matras on its ſide, that he may decant the liquor more conveniently when all is precipitated that is not taken up by the ſolvent.

"The ſecond veſſel, into which the liquor is firſt decanted, he alſo lays declining, that a new precipitation of the undiſſolved matters may be obtained; after which he pours the liquor into a third veſſel. This liquor muſt not be filtered, if you would have the reſt of the proceſs ſucceed perfectly; becauſe the *aqua fortis* would diſſolve ſome of the paper, and that would ſpoil the colour of your liquor.

"When this ſolution, which Mr Hellot calls the *impregnation*, is thoroughly clarified by being decanted three or four times, he puts it into a glaſs baſon with two ounces of very pure ſea-ſalt. The fine white ſalt made by the ſun ſucceeded beſt with Mr Hellot. If that cannot be had, common bay-ſalt purified by ſolution, filtration, and cryſtalliſation, may be uſed inſtead of it. But as it is rare to meet with any of the ſort that is not a little tainted with iron, the white bay ſalt is to be preferred. The glaſs baſon he ſets in a gentle ſand-heat, and keeps it there till the mixture be reduced by evaporation to an almoſt dry ſaline maſs.

"If you deſire to ſave the *aqua regis*, the impregnation muſt be put into a retort, and diſtilled with the gentle heat of a ſand-bath. But there is an inconvenience, as Mr Hellot obſerves, in employing a retort; which is, that, as the ſaline maſs cannot be ſtirred while it coagulates in the retort, it is reduced to a compact cake of coloured ſalt, which preſents but one ſingle ſurface to the water in which it muſt be diſſolved; ſo that the diſſolution thereof takes up ſometimes no leſs than five or ſix days. In the baſon, on the contrary, the ſaline maſs is eaſily brought to a granulated ſalt, by ſtirring it with a glaſs rod; and, when thus granulated, it has a great deal more ſurface; it diſſolves more eaſily, and yields its tincture to water in four hours time. Indeed one is more expoſed to the vapours of the ſolvent, which would be dangerous, if the operation were to be often performed, without proper precautions.

"When the baſon, or little veſſel containing the mixture of the impregnation and ſea ſalt, is heated, the liquor, which was of an orange-coloured red, becomes a crimſon red; and, when all the phlegm of the ſolvent is evaporated, it acquires a beautiful emerald colour. By degrees it thickens, and turns of the colour of a maſs of verdegris. It muſt then be carefully ſtirred with the glaſs rod, in order to granulate the ſalt, which muſt not be kept over the fire till it be perfectly dry: becauſe you run a riſk of loſing irrecoverably the colour you are ſeeking. You may be ſure you have loſt it, if by too much heat the ſalt that was of a green colour turn to a dirty yellow. If it be once brought to this ſtate, it will continue without changing when cold: but if care be taken to remove it from the fire while it is ſtill green, you will ſee it gradually grow pale, and become of a beautiful roſe-colour as it cools.

"Mr Hellot ſeparates it from this veſſel, and throws it into another containing diſtilled rain-water: and this ſecond veſſel he keeps in gentle digeſtion, till he obſerves that the powder which falls to the bottom is perfectly white. If, after three or four hours digeſting, this powder ſtill continues tinged with a roſe colour, it is a proof that water enough was not added to diſſolve all the ſalt

falt impregnated with the tincture of the folution. In this cafe, the firft tinged liquor muft be poured off, and frefh water added in proportion to the quantity of tinged falt that is fuppofed to remain mixed with the precipitate.

" When the ore is pure, and doth not contain a great deal of fufible ftone, commonly called *fluor*, or *quartz*, an ounce of it generally yields tincture enough for eight or nine ounces of water, and the liquor is of a beautiful colour, like that of the lilach or pipe-tree bloffom. In order to prove the effect of this tincture, you muft write with this lilach-coloured liquor on good well-gummed paper, that does not fink: or you may ufe it to fhade the leaves of fome tree or plant, having firft drawn the outlines thereof lightly with China ink or with a black lead pencil. Let this coloured drawing, or writing, dry in a warm air. You will perceive no colour while it is cold; but, if it be gently warmed before the fire, you will fee the writing, or the drawing, gradually acquire a blue or greenifh blue colour, which is vifible as long as the paper continues a little warm, and difappears entirely when it cools."

The fingularity of this fympathetic ink confifts in its property of difappearing entirely, and becoming invifible, though it be not touched with any thing whatever: and this diftinguifhes it from all others; which, when once rendered vifible by the application of proper means, do not again difappear, or at leaft not without touching the ftrokes on the paper with fome other liquor.

Of ZINC.

To extract Zinc from its Ore, or from Calamine.

TAKE eight parts of calamine reduced to a powder; mix this powder accurately with one part of fine charcoal duft, previoufly calcined in a crucible to free it from all moifture: put this mixture into a ftone retort coated with lute, leaving a third part of it empty: fet your retort in a reverberatory furnace, capable of giving a very fierce heat. To the retort apply a receiver, with a little water in it. Kindle the fire, and raife it by degrees till the heat be ftrong enough to melt copper. With this degree of fire the zinc being metallifed will feparate from the mixture, and fublime into the neck of the retort, in the form of metallic drops. Break the retort when it is cold, and collect the zinc.

Moft of the zinc we have comes from an ore of difficult fufion that is worked at Goflar, and yields, at one and the fame time, lead, zinc, and another metallic matter called *cadmia fornacum*, which alfo contains much zinc.

The furnace ufed for fmelting this ore is clofed on its fore-fide with thin plates or tables of ftone, not above an inch thick. This ftone is greyifh, and bears a violent fire.

In this furnace the ore is melted amidft charcoal, by the help of bellows. Each melting takes twelve hours, during which time the zinc flowing with the lead is refolved into flowers and vapours, great part of which adheres to the fides of the furnace in the form of a very hard cruft of earth. The workmen take care to remove this cruft from time to time; for it would otherwife grow fo thick at laft, as to leffen the cavity of the furnace very confiderably.

There adheres moreover to the fore-part of the furnace, which is formed, as we faid before, of thin plates of ftone, a metallic matter, which is the zinc, and is carefully collected at the end of each melting, by removing from this part all the live coals. A quantity of fmall coal is laid unlighted at the bottom; and on this fmall-coal, by ftriking the ftone-plates gently with a hammer, the zinc is made to fall out of the other matter, known by the Latin name of *cadmia fornacum*, among which it appears fixed in a radiated form. To this other matter we may properly enough give the name of *furnace-calamine*. The zinc falls in the form of a melted metal, all on fire, and in a bright flame. It would foon be entirely burnt and reduced to flowers, if it were not extinguifhed, and eafily cooled and fixed, by being hid under the unlighted fmall-coal placed below on purpofe to receive it.

The zinc adheres to the fore-part of the furnace preferably to any other, becaufe that being the thinneft, is therefore the cooleft: and, in order further to promote its fixing on this part, they take care to keep the thin ftone-plates cool during the operation, by throwing water on them.

Hence it appears that zinc is not extracted from its ore by fufion and the precipitation of a regulus, like other metallic fubftances. This is owing to the great volatility of our femi-metal, which cannot, without fubliming, bear the degree of fire neceffary to melt its ore. It is at the fame time fo combuftible, that a great part of it rifes in flowers which have not the metalline form.

To fublime Zinc into Flowers.

TAKE a very deep, large crucible: place this crucible in a furnace, fo that it may ftand inclining in an angle of forty-five degrees nearly. Throw fome zinc into it, and kindle a fire in the furnace fomewhat ftronger than would be neceffary to keep lead in fufion. The zinc will melt. Stir it with an iron wire, and there will appear on its furface a very bright white flame: two inches above this flame a thick fmoke will be formed, and with this fmoke exceeding white flowers will rife, and remain fome time adhering to the fides of the crucible, in the form of a very fine light down. When the flame flackens, ftir your melted matter again with the iron wire: you will fee the flame renewed, and the flowers begin again to appear in greater abundance. Go on thus till you obferve that the matter will not flame, nor any more flowers rife.

To combine Zinc with Copper. Brafs. Prince's Metal, &c.

POUND one part and an half of calamine, and an equal quantity of charcoal: mingle thefe two powders together, and moiften them with a little water. Put this mixture into a large crucible, or fome other earthen veffel that will bear a melting heat. Amongft and over this mixture put one part of very pure copper in thin plates, and then put frefh charcoal-duft over all: clofe the

the crucible; ſet it in a melting furnace; put coals all round it, and let them kindle gradually. Raiſe the fire ſo as to make the crucible very red-hot. When you obſerve that the flame hath acquired a purple or blueiſh-green colour, uncover the crucible, and dip into it an iron wire, to examine whether or no the copper be in fuſion under the charcoal duſt. If you find it is, moderate the force of the fire a little, and let your crucible remain in the furnace for a few minutes. Then take it out and let it cool: you will find your copper of a gold colour, increaſed in weight a fourth, or perhaps a third part, and yet very malleable.

The *lapis calaminaris* is not the only ſubſtance with which copper may be converted into braſs: all other ores containing zinc, the furnace-calamine that ſublimes where ſuch ores are worked, tutty, zinc in ſubſtance, may be ſubſtituted for it, and, like it, will make very fine braſs; but, in order to ſucceed, ſundry precautions are neceſſary.

This proceſs is a ſort of cementation; for the calamine doth not melt; only the zinc is converted into vapours, and then combines with the copper. On this the ſucceſs of the operation partly depends, as it is the means of the copper's preſerving its purity and malleability; becauſe the other metallic ſubſtances that may be united with the ore of zinc, or with the zinc itſelf, not having the ſame volatility, cannot be reduced to vapours. If you are appriſed that the calamine, or other ore of zinc uſed on this occaſion, is contaminated with a mixture of any other metallic matter, you muſt mingle luting earth with the charcoal-duſt and the matter containing the zinc; make it into a ſtiff paſte with water; of this make a bed at the bottom of your crucible, and ram it hard down; lay the copper-plates thereon, cover them with charcoal-duſt, and then proceed as before. By this means, when the copper melts, it cannot fall to the bottom of the crucible, nor mix with the ore; but is borne up by the mixture, and cannot combine with any thing but the zinc, that riſes in vapours, and, paſſing through the lute, fixes in the copper.

Lapis Calaminaris, or other ore of zinc, may be alſo purified before it be uſed for making braſs; eſpecially if adulterated with lead ore, which is often the caſe. For this purpoſe the ore muſt be roaſted in a fire ſtrong enough to give a ſmall degree of fuſion to the leaden matter; which will thereby be reduced into larger, heavier, and tougher maſſes. The moſt ſubtile particles are diſſipated in the torrefaction, together with ſome of the calamine. The calamine, on the contrary, is by roaſting made more tender, lighter, and much more friable. When it is in this condition, put it into a waſhing tray or fan; dip the tray in a veſſel full of water, and bruiſe the matter it contains. The water will carry off the lighteſt powder, which is the calamine, and leave nothing at the bottom of the tray but the heavieſt ſubſtance; that is, the leaden matter, which is to be rejected as uſeleſs. The powder of the calamine will ſettle at the bottom of the veſſel, where, after pouring off the water, it may be found, and uſed as above directed.

In this operation the charcoal-duſt ſerves to prevent both the copper and the zinc from being calcined: and for this reaſon, when you work on a great quantity of materials at once, it is not neceſſary to uſe ſo much charcoal-duſt, in proportion, as when you work but on a ſmall quantity; becauſe, the greater the maſs of metal, the leſs eaſily will it calcine.

Though the copper melts in this operation, yet it is far from being neceſſary to apply ſuch a ſtrong fire as copper uſually requires to melt it: for the acceſſion of the zinc, on this occaſion, communicates to it a great degree of fuſibility. The increaſe of its weight is alſo owing to the quantity of zinc combined with it. Copper acquires ſtill another advantage by its aſſociation with this ſemi-metal; for it remains longer in the fire without calcining.

Braſs well prepared ought to be malleable when cold. But in whatever manner it be made, and whatever proportion of zinc there be in it, it is conſtantly found quite unmalleable when red-hot.

Braſs melted in a crucible, with a fierce heat, takes fire almoſt like zinc, and from its ſurface many white flowers aſcend, dancing about in flakes like the flowers of zinc. They are indeed the flowers of zinc, and the flame of braſs urged by a ſtrong fire is no other than the flame of the zinc that is united with the copper, and then burns. If braſs be thus kept long in fuſion, it will loſe almoſt all the zinc it contains. It will alſo loſe much of its weight, and its colour will be nearly that of copper. It is therefore neceſſary, towards performing this operation aright, to ſeize the moment when the copper is ſufficiently impregnated with zinc, when it hath acquired the moſt weight and the fineſt colour, with the leaſt detriment to its ductility, that is poſſible, and that inſtant to put out the fire; becauſe, if the copper be left longer in fuſion, it will only loſe the zinc already united with it. Skill acquired by much practice, and an acquaintance with the particular calamine employed, are neceſſary to guide the artiſt ſurely through this operation; for there are very conſiderable differences between the ſundry ores of zinc. Some of them contain lead, and in others there is iron. When theſe heterogeneous metals come to be mixed with the copper, they do indeed augment its weight, but they render it at the ſame time pale, and make it very harſh. Some calamines require to be roaſted before they can be uſed for this purpoſe, and in the torrefaction emit vapours of a volatile alkali, ſucceeded by vapours of a ſulphureous ſpirit: others exhale no vapours while roaſting, and may be employed without any antecedent preparation. Theſe different qualities muſt evidently produce great differences in the operation.

Braſs may alſo be made, as prince's metal and other imitations of gold are actually made, by uſing zinc in ſubſtance, inſtead of the ores that contain it. But theſe compoſitions have not, when cold, the ductility of braſs prepared with *lapis calaminaris*, becauſe zinc is ſeldom pure, or free from a mixture of lead. Perhaps alſo the different manner in which the zinc unites with the copper may contribute to this variation.

To obviate this inconvenience, the zinc muſt be refined from all alloy of lead. The property of being indiſſoluble by ſulphur, which this ſemi-metal poſſeſſes, points out

out a very practicable method of doing it. The zinc muſt be melted in a crucible, and ſtirred briſkly with a ſtrong iron wire, while tallow and mineral ſulphur are alternately projected upon it; but ſo that the quantity of ſulphur may greatly exceed that of the tallow. If the ſulphur do not burn entirely away, but form a kind of ſcoria on the ſurface of the zinc, it is a ſign that your ſemi-metal contains lead. In this caſe you muſt continue throwing in more ſulphur, and keep ſtirring the zinc inceſſantly, till you perceive that the ſulphur ceaſes to unite any more with a metallic ſubſtance, but burns freely on the ſurface of the zinc. The ſemi-metal is then refined; becauſe the ſulphur, which cannot diſſolve it, unites very readily with the lead, or other metallic ſubſtance, contained in it.

If zinc thus refined be mixed with pure copper, in the proportion of a fourth or a third part, and the mixture be kept in fuſion and conſtantly ſtirring for ſome time, the braſs produced will be as ductile, when cold, as that made by cementation with the *lapis calaminaris*.

With regard to prince's metal, and other imitations of gold, they are made either with copper or braſs recombined with more zinc. As it is neceſſary, for giving them a fine golden colour, to mix with them other proportions of zinc than that required to make braſs only, they are generally much leſs ductile.

Zinc diſſolved in the Mineral Acids.

Weaken concentrated oil of vitriol by mixing with it an equal quantity of water. Into a matras put the zinc you intend to diſſolve, firſt broken to ſmall pieces. Pour on it ſix times its weight of the vitriolic acid, lowered as above directed, and ſet the matras in a ſand-bath gently heated. The zinc will diſſolve entirely, without any ſediment. The neutral metallic ſalt reſulting from this diſſolution ſhoots into cryſtals, which go by the name of *white vitriol*, or *vitriol of zinc*.

Zinc is diſſolved by the nitrous and marine acids, much in the ſame manner as by the vitriolic; except that the marine acid does not touch a black, ſpungy, rarefied matter, which it ſeparates from the zinc. M. Hellot found upon trial that this matter is not mercury, and that it cannot be reduced to a metallic ſubſtance.

A ſolution of zinc in the marine acid, being diſtilled to dryneſs, yields a ſublimate on applying a violent heat to it.

All the acids diſſolve with eaſe; not only zinc, but its flowers alſo; and that nearly in the ſame quantity, and with almoſt all the ſame phenomena.

Of Arsenic.

To extract Arſenic from its Matrices Zaffre or Smalt.

Powder ſome cobalt, white pyrites, or other arſenical matters. Put this powder into a retort with a ſhort wide neck, leaving a full third thereof empty. Set your retort in a reverberating furnace; lute on a receiver; heat your veſſel by degrees, and increaſe the fire till you ſee a powder ſublime into the neck of the retort. Keep up the fire in this degree as long as the ſublimation continues: when this begins to ſlacken, raiſe your fire, and make it as ſtrong as the veſſels will bear. When nothing more aſcends, let it go out. On unluting the veſſels, you will find in the receiver a little arſenic in the form of a fine light *farina*. The neck of the retort will be full of white flowers, not quite ſo fine, ſome of which will appear like little cryſtals; and if a good deal of arſenic be ſublimed, a ponderous matter, like a white, ſemi-tranſparent glaſs, will be found adhering to that part of the neck of the retort which is next its body.

When all the arſenic the cobalt will yield is thus ſeparated, the earthy fixed matter left behind is mixed with divers fuſible matters and vitrified, and produces a glaſs of beautiful blue colour. It is called *ſmalt*. This glaſs is to be prepared in the following manner.

Take four parts of fine fuſible ſand, an equal quantity of any fixed alkali perfectly depurated, and one part of cobalt from which the arſenic hath been ſublimed by torrefaction. Pulveriſe theſe different ſubſtances very finely, and mix them thoroughly together; put the mixture into a good crucible, cover it, and ſet it in a melting furnace. Make a ſtrong fire, and keep it up conſtantly in the ſame degree for ſome hours. Then dip an iron wire into the crucible; to the end of which a glaſſy matter will ſtick, in the form of threads, if the fuſion and vitrification be perfect. In this caſe take the crucible out of the fire; cool it by throwing water on it, and then break it. You will find in it a glaſs, which will be of an exceeding deep blue, and almoſt black, if the operation hath ſucceeded. This glaſs, when reduced to a fine powder, acquires a much brighter and more lively blue colour.

If you find after the operation that the glaſs hath too little colour, the fuſion muſt be repeated a ſecond time, with twice or thrice the quantity of cobalt. If, on the contrary, the glaſs be too dark, leſs cobalt muſt be uſed.

In order to make the eſſay of a particular cobalt, with a view to know what quantity of blue glaſs it will yield, it is not neceſſary to perform the operation in the manner here ſet down; a great deal of time and trouble may be ſaved by melting one part of cobalt with two or three parts of borax. This ſalt is very fuſible, and turns, when melted, into a ſubſtance which, for a time, poſſeſſes all the properties of glaſs. In this trial the glaſs of borax will be nearly of the ſame colour as the true glaſs, or ſmalt, made with the ſame cobalt.

The ores of biſmuth, as well as cobalt, yield a matter that colours glaſs blue; nay, the ſmalt made with thoſe ores is more beautiful than that procured from the ore of pure arſenic. Some cobalts yield both arſenic and biſmuth. When ſuch cobalts are uſed, it is common to find at the bottom of the crucible a little button of metallic matter, which is called *regulus of cobalt*. This regulus is a ſort of biſmuth, generally adulterated with a mixture of ferruginous and arſenical parts.

The heavieſt and moſt fixed flowers of arſenic, procured from cobalt, have likewiſe the property of giving a blue colour to glaſs. But this colour is faint: it is owing to a portion of the colouring matter carried up along with the arſenic. Theſe flowers may be made an ingredient in the compoſition of blue glaſs, not only becauſe of the colouring principle they contain, but alſo becauſe

they greatly promote fusion; arsenic being one of the most efficacious fluxes known.

In short, all those blue glasses, or smalts, contain a certain quantity of arsenic; for a portion of this semimetal always remains united with the fixed matter of the cobalt, though roasted for a long time, and in a very hot fire. The portion of arsenic that is thus fixed vitrifies with the colouring matter, and enters into the composition of the smalt.

The blue glass made with the fixed part of cobalt hath several names, according to the condition in which it is.

When it hath undergone the first imperfect degree of fusion only, it is called *zaffre*. It takes the name of *smalt* when perfectly vitrified: and this again being pulverised is called *powder blue*; or, if finely levigated, *blue enamel*; because it is used in enamelling, as well as in painting earthen ware and porcelain.

To separate Arsenic from Sulphur.

Powder the yellow or red arsenic which you intend to separate from its sulphur. Moisten this powder with a fixed alkali resolved into a liquor. Dry the mixture gently; put it into a very tall glass cucurbit, and fit on a blind-head. Set this cucurbit in a sand-bath; warm the vessels gently, and increase the fire by degrees, till you perceive that no more arsenic sublimes. The arsenic, which before was yellow and red, rises into the head partly on white flowers, and partly in a compact, white, semi-transparent matter, which looks as if it were vitrified. The sulphur combined with the fixed alkali remains at the bottom of the cucurbit.

To give Arsenic the Metalline Form. Regulus of Arsenic.

Take two parts of white arsenic in fine powder, one part of the black flux, half a part of borax, and as much clean iron filings. Rub the whole together, in order to mix them thoroughly. Put this mixture into a good crucible, and over it put sea-salt three fingers thick. Cover the crucible; set it in a melting furnace; and begin with a gentle fire to heat the crucible equally.

When arsenical vapours begin to ascend from the crucible, raise the fire immediately so as to melt the mixture. Examine whether or no the matter be thoroughly melted, by introducing an iron wire into the crucible; and if the fusion be perfect, take the crucible out of the furnace. Let it cool; break it; and you will find in it a regulus of a white and livid metallic colour, very brittle, scarcely hard, but rather friable.

To distil the Nitrous Acid by the Interposition of Arsenic. Blue Aqua Fortis.

Pulverise finely any quantity you please of refined salt-petre. Mix it accurately with an equal weight of white crystalline arsenic well pulverised, or else with very white and very fine flowers of arsenic. Put this mixture into a glass retort, leaving one half of it empty. Set your retort in a reverberating furnace; apply a receiver, having a small hole drilled in it, and containing a little filtered rain-water; lute the receiver to the retort with stiff lute. Begin with putting two or three small live coals in the ash-hole of the furnace, and replace them with others when they are ready to go out. Go on thus warming your vessels by insensible degrees, and put no coals in the fire-place till the retort begin to be very warm. You will soon see the receiver filled with vapours of a dark red, inclining to a russet colour. With a bit of lute stop the little hole of the receiver. The vapours will be condensed in the water of this vessel, and give it a very fine blue colour, that will grow deeper and deeper as the distillation advances. If your salt-petre was not very dry, some drops of acid will also come over, and falling from the nose of the retort mix with the water in the receiver. Continue your distillation, increasing the fire little by little as it advances, but exceeding slowly, till you see that when the retort is red-hot nothing more comes off; and then let your vessels cool.

When the vessels are cold, unlute the receiver, and as expeditiously as you can pour the blue *aqua fortis* it contains into a crystal bottle; which you must seal hermetically, because this colour disappears in a short time when the liquor takes air. You will find in the retort a white saline mass moulded in its bottom, and some flowers of arsenic sublimed to its upper cavity, and into its neck.

Pulverise the saline mass, and dissolve it in warm water. Filter the solution, in order to separate some arsenical parts that will be left on the filter. Let the filtered liquor evaporate of itself in the open air; when it is sufficiently evaporated, crystals will shoot in it representing quadrangular prisms terminated at each extremity by pyramids that are also quadrangular. These crystals will be in confused heaps at the bottom of the vessel: Over them will be other crystals in the form of needles; a saline vegetation creeping along the sides of the vessel; and the surface of the liquor will be obscured by a thin dusty pellicle.

To alkalisate Nitre by Arsenic.

Melt in a crucible the nitre you intend to alkalisate. When it is melted, and moderately red, project upon it two or three pinches of pulverised arsenic. A considerable effervescence and ebullition will immediately be produced in the crucible, attended with a noise like that which nitre makes when it detonates with an inflammable matter. At the same time a thick smoke will rise, which at first will smell like garlick, the odour peculiar to arsenic; it will also smell afterwards like spirit of nitre. When the effervescence in the crucible is over, throw again upon the nitre as much pulverised arsenic as you did the first time; and all the same phenomena will be repeated. Continue thus throwing in arsenic in small parcels, till it produce no more effervescence; taking care to stir the matter at every projection with an iron wire, the better to mix the whole together. Then increase your fire, and melt what remains. Keep it thus in fusion for a quarter of an hour, and then take the crucible out of the fire. It will contain a nitre alkalised by arsenic.

Of Vegetables.

Of the Subſtances obtained from Vegetables by Expreſſion only.

To expreſs and depurate the Juice of a Plant, containing its Eſſential Salt. The Cryſtalliſation of that Salt.

Before ſun-riſe, gather a good quantity of the plant, from which you deſign to expreſs the juice, in order to obtain its ſalt. Waſh it well in running water, to clear it of earth, inſects, and other adventitious matters. Bruiſe it in a marble mortar; put it into a bag of new, ſtrong, thick linen cloth; tie the bag tight, and commit it to a preſs. By preſſing it ſtrongly you will ſqueeze out a great quantity of green, thick juice, which will have the ſame taſte as the plant. Dilute this juice with ſix times as much pure rain water, and filter it repeatedly through a woolen bag, till it paſs clear and limpid. Evaporate the filtered juice with a gentle heat, till it be almoſt as thick as before it was mixed with water. Put this inſpiſſated juice into a jar, or other veſſel of earth or glaſs; on its ſurface pour olive oil to the depth of a line, and ſet it in a cellar. Seven or eight months after this pour off gently the liquor contained in the veſſel, the inſide of which you will find covered with a cryſtalliſed ſalt. Separate the cryſtals gently; waſh them quickly with a little fair cold water, and dry them: this is the eſſential oil of the plant.

Every plant is not equally diſpoſed to yield its eſſential ſalt by the method here propoſed. Succulent vegetables only, whoſe juices are aqueous and not too viſcous, are fit for this purpoſe. Such, for example, as ſorrel, brook-lime, ſuccory, fumitory, water-creſſes, plantain, *&c.* An eſſential ſalt cannot be procured from thoſe that yield thick, viſcid, mucilaginous juices, ſuch as the ſeeds of flea-wort, unleſs their juices be previouſly attenuated by fermentation, and that viſcoſity deſtroyed which obſtructs the cryſtalliſation of this ſalt.

Nor can the eſſential ſalt be obtained in any quantity from vegetable matters abounding in oil. Moſt kernels and ſeeds are of this ſort: they all contain a great quantity of fat oil, which ſo entangles and clogs this ſalt, that the particles thereof cannot ſhoot away from the tenacious juices into cryſtals.

The ſame is to be ſaid of dry aromatic plants; becauſe they contain much eſſential oil, or reſinous matters that produce the ſame effect. It is true, the eſſential ſalt itſelf contains a certain portion of oil; for it is no other than the acid of the plant incorporated and cryſtalliſed with part of its oil and of its earth: but then the oil muſt not be in too great a quantity; becauſe it ſheaths the acid, renders it clammy, as it were, and hinders it from extricating itſelf ſo as to be able to exert its qualities, and appear in the form of ſalt.

The juice of plants obtained by expreſſion is very thick; becauſe it contains many particles of the bruiſed plant that are unavoidably ſqueezed out along with it. In order to clear it of theſe ſuperfluous parts it is proper to filter it: but as that would be difficult, on account of the thickneſs of the juice, it muſt be thinned, by diluting it with a quantity of water, ſufficient to give it the requiſite degree of fluidity.

Inſtead of thus diluting the expreſſed juice, the plant may be ground with water before it is put into the preſs: it will by this means furniſh a more fluid juice, that will eaſily paſs through the filter. This method may be employed with ſucceſs on dry plants, or ſuch as are not very ſucculent. For this operation rain-water is to be preferred to any other; becauſe it is the pureſt.

The juice of the plant, when diluted with the quantity of water ſufficient to facilitate its filtration, is too aqueous to let the ſalt it contains unite into cryſtals: It muſt therefore be evaporated till it hath recovered a ſomewhat thicker conſiſtence. The heat applied for that purpoſe muſt be gentle; leſt the acid and oily parts that are to form the ſalt, be ſpoiled or diſſipated, as they are not very fixed.

The oil poured on the liquor prevents its fermenting, putrefying, or growing mouldy, during the long ſpace of time required for the cryſtalliſation of the eſſential ſalt.

Theſe ſalts are excellent medicines, being endued with the ſame virtues as the plants from which they were obtained.

To draw the Oils out of Kernels, Seeds, and Fruits, by Expreſſion.

Pound in a marble mortar, or grind in a mill, the kernels, ſeeds, or fruits, out of which you intend to expreſs the oil. If your matters be meagre, and grind to meal, ſuſpend that meal in the ſteam of boiling water, in order to moiſten it a little, and then dry it.

Tie up your matters thus prepared in a new, ſtrong, thick canvaſs bag, and put it into a preſs, between two iron plates previouſly heated in boiling water: ſqueeze it ſtrongly, and you will ſee the oil run in ſtreams into the receiving veſſel.

To draw the Eſſential Oil of certain Fruits by Expreſſion.

Take the rind of a citron, lemon, orange, Bergamot-pear, or other fruit of that kind; cut it in ſlices, and doubling the ſlices ſqueeze them between your fingers over againſt a poliſhed glaſs ſet upright, with its lower end in a veſſel of earth or porcelain. Every time you ſqueeze the peel in a new ply, there will ſquirt out of it ſeveral fine jets of liquor, which, meeting with the ſurface of the glaſs, will be condenſed into drops, and trickle down in ſmall ſtreams into the recipient. This liquor is the eſſential oil of the fruit.

Of the Subſtances obtained from Vegetables by Trituration.

To make the Extracts of a Plant by Trituration.

Bruise the vegetable ſubſtance of which you intend to make the extracts; or, if it be hard and dry, grind it to a powder: put the matter thus prepared, together with ſeven or eight times as much rain-water, into an earthen veſſel; and into this veſſel fit a churning ſtaff, ſo that

that it may be continually whirled round with a rotatory motion, by means of a cord, a wheel, and a winch. Ply this machine for ten or twelve hours; and then filter the liquor through two linen cloths ſpread on a hair-ſieve. Let your filtered liquor ſtand quiet for twelve hours more: Then pour it off by inclination from the ſediment you will find at bottom; and filter it a ſecond time through a flannel bag.

Pour freſh water, but in a ſmaller quantity, on the maſs left after trituration with the machine. Triturate it again for four or five hours. Treat the liquor of this ſecond triture juſt as you did that of the firſt, and mix them both together. Diſtribute all the liquor you now have among a ſufficient number of ſhallow earthen plates, and evaporate it by a gentle heat, ſuch as that of the ſun, or of a vapour-bath, to the conſiſtence of an extract, or even to dryneſs, as you think proper.

To extract from Seeds and Kernels, by Trituration, the Matter of Emulſions.

Blanch the kernels of which you deſire to make an emulſion; put them into a marble mortar; add a very little water; and pound them with a wooden peſtle. Continue pounding and triturating till the matter become like a white paſte. From time to time pour on it, by little and little, more fair water warmed, ſtill continuing the trituration; by which means the paſte will grow thinner. Go on thus till every particle of your kernels be cruſhed to pap. Then add, ſtill rubbing the mixture, enough of water to make the whole an actual fluid; and you will have a liquor of a dead-white colour, reſembling milk. Strain it through a clean linen cloth: it will leave on the filter ſome coarſe parts, which muſt be returned to thoſe left in the mortar. Again triturate and rub the remainder of the kernels, with the addition of water as before. This ſecond liquor will not be ſo white nor ſo rich as the former: filter it in the ſame manner, and again grind with water the ſolid parts remaining. In this manner proceed, repeatedly rubbing and adding freſh water, till it appear no longer milky, but come off clear. The white milky waters thus obtained go by the name of an *emulſion*.

All the matters, from which a fat oil is obtainable by expreſſion, produce emulſions when triturated with water.

An emulſion conſiſts chiefly of two ſubſtances. One of theſe is mucilaginous, and ſoluble in water. This ſubſtance by itſelf would not give a milky appearance to the emulſion, which, with it alone, would be limpid. The other is a fat oil, which of itſelf is not ſoluble in water; but being divided by the means of trituration into very ſmall globules, it is diſperſed through the whole liquor, and ſuſpended therein by the aid of the mucilaginous part. It is this oily part that gives the emulſion its dead-white milky colour; becauſe it is not actually diſſolved in the water, but only diffuſed through it.

If oil be mixed with water in a phial, and the mixture ſtrongly ſhaken for ſome time, with a rapid and continued motion, the oil will be divided into a vaſt number of little globules, which intervening between the parts of the water will deſtroy its tranſparency, and give it a dead-white colour, like that of our emulſion. But, as the oil is not ſo minutely divided by this means as by triturating the matters containing it; and again, there being no mucilage in this liquor, as there is in emulſions, the oil ſoon ſeparates from the water when it is left at reſt, re-unites into round globules, and theſe joining together riſe to the ſurface of the liquor, which then recovers its tranſparency.

The caſe is not exactly the ſame with emulſions; but ſomething like it happens to them alſo. If they be left to ſtand quiet in a long bottle, the liquor, which at firſt appeared homogeneous, ſeparates into two manifeſtly different parts. The upper part retains its dead-white colour, but is thicker and more opaque; while the lower part becomes perfectly tranſparent. This is the beginning of an entire ſeparation of the oily from the aqueous parts. The former, being the lighter, aſcend and gain the upper part of the liquor; while the lower, being freed from that which obſtructed its tranſlucence, recovers its proper limpidity: but the oily parts do not reunite into maſſes large enough to form one homogeneous whole, with the appearance and limpidneſs of oil; their being minutely divided and entangled in the mucilage impeding their natural tendency.

Emulſions firſt begin to ſpoil, as they grow old, not by turning rancid and acrimonious like the fat oils drawn by expreſſion, but by turning ſour; which is owing to the great quantity of mucilage they contain. As there is a fat oil in their compoſition, they have the ſame virtues with that ſort of oil: but they are moreover incraſſating, cooling, and emollient; qualities which render them extremely uſeful in acute and inflammatory diſorders. They grow ſour in a very ſhort time, eſpecially in the heat of ſummer; nay, they ſometimes do ſo in two hours: and therefore they ought to be prepared from time to time as they are to be uſed.

The matter that is left when all the ſubſtance of the emulſion is extracted, and from which the water comes off clear and limpid, is ſcarce any thing but the earthy part of the ſeed or kernel that was triturated; which, however, ſtill retains a portion of tenacious and groſs oil, adhering to it ſo firmly as not to be ſeparable by water.

The chyle and milk of animals reſemble an emulſion in ſeveral reſpects, and particularly in their dead-white colour; which ariſes, in the ſame manner, from the very minute particles of oil contained in them, and diſtributed through an aqueous gelatinous fluid, but not diſſolved therein. In general, whenever any oil of any kind happens to be lodged in this manner between the parts of an aqueous liquor, it always makes the whole of an opaque white: for oil will not mix with water, ſo as to produce a liquor that ſhall appear homogeneous and tranſparent, unleſs it be intimately diſſolved in the water; which cannot be effected but by means of an union previouſly contracted between it and ſome ſaline matter; as is the caſe of mucilages, certain ſaponaceous matters, and ſome other combinations of which we ſhall have occaſion to treat in the ſequel.

The methods we have hitherto propoſed, for extracting from vegetable ſubſtances all that they will yield without

without the affiftance of fire, are not capable of analyfing thofe fubftances accurately; fince by expreffion and trituration we obtain only the liquid parts, impregnated indeed with almoft all the principles of plants, which however are ftill combined with each other, and barely feparated from the groffeft earthy and oily parts. We muft therefore neceffarily have recourfe to a more effectual expedient for carrying our analyfis further. This expedient confifts in making them undergo the action of fire, fucceffively graduated, from the gentleft to the moft violent heat.

But, before we enter on this analyfis of vegetables, it is proper to defcribe the different operations that may be performed on oils, the only pure principle we have been able to obtain without the help of fire.

Of Operations on Fat Oils.

To attenuate Fat Oils, and change their Nature, by expofing them to the Action of Fire, and diftilling them.

Mix thoroughly three or four pounds of any fat oil whatever with twice its weight of lime flaked in the air. Put this mixture into a large earthen retort, leaving a third part of it empty. Set it in a reverberating furnace, and lute on a receiver. Heat the veffel with a very gentle fire. A little flame will rife firft, and will foon be followed by an oil that will fall in drops from the nofe of the retort. Continue the diftillation very flowly, till you perceive the oil that comes over begin to be not quite fo fluid as before, but rather a little thicker.

Then unlute your receiver, and put another in its place. Continue the diftillation, increafing your fire by degrees. The oil that comes over will grow thicker and thicker, its fluidity will decreafe, and it will acquire a dark-brown colour, which at laft will become blackifh. The oil will then be very thick. Pufh the operation till nothing more will come off, though the retort be red-hot. During the whole time this diftillation lafts, there rifes a good deal of water in company with the oil. Keep the fecond thick oil by itfelf.

Mix the oil that came over firft in this operation with an equal part of frefh lime flaked in the air. Put the mixture into an earthen or glafs retort, of a fize fo proportioned to the quantity, that a third part thereof may remain empty. Diftill as before. The fame phenomena will appear: a clear oil will firft come over, and be fucceeded by one a little thicker. Then fhift your receiver, and diftill off all the reft of the oil with an increafed fire. The firft oil obtained by this fecond diftillation will be clearer and thinner than that of the firft diftillation; and the fecond oil will not be fo thick nor of fo deep a colour as before.

Diftill over again in the fame manner the thin oil of this fecond diftillation, and go on thus repeatedly diftilling, till the firft clear oil come over with a degree of heat not exceeding that of boiling water. Then, inftead of mixing your oil with lime, put it with fome water into a glafs retort, or into a body with its head fitted on, and diftill it, keeping the water juft in a fimmer. Your oil will be more and more attenuated, and, after being thus diftilled twice or thrice with water, will be fo limpid, fo thin, and fo clear, that you will fcarce be able to diftinguifh it from water itfelf.

To combine Fat Oils with Acids.

Put any fat oil whatever into a glafs bafon, and fet it in a fand-bath very moderately heated. Pour on this oil an equal quantity of concentrated oil of vitriol, which will immediately diffolve it with violence; a confiderable ebullition and effervefcence will arife, attended with great heat, and a prodigious quantity of black thick vapours, in which may be eafily perceived the fmell of burnt oil, together with that of a fulphureous acid. The mixture will become of a deep-red, black, and thick. Stir it with a fmall ftick, till you obferve that all is quiet.

To combine Fat Oils with Fixed Alkalis. Hard and Soft Soap. The Decompofition of Soap.

Take a lixivium of Alicant kelp made more cauftic by lime, as we fhall fhew when we come to fpeak of alkalis. Evaporate this lye till it be capable of bearing a new-laid egg. Divide it into two parts; and to one of thefe put juft water enough to weaken it fo that a new laid egg will not fwim in it, but fall to the bottom. With the lye thus weakened, mix an equal quantity of frefh-drawn olive oil. Stir and agitate the mixture well till it become very white. Set it over a gentle fire, and continue ftirring it inceffantly, that the two ingredients of which it is compounded may gradually combine together, as part of the water evaporates. When you perceive they begin to unite, pour into the mixture thrice as much of the firft ftrong lye as you took of olive oil. Continue the coction with a gentle fire, always ftirring the matter, till it become fo thick that a drop of it fixes, as it cools, into the confiftence that foap ought to have. By diffolving a little of this foap in water, you will difcover whether or no it contains more oil than ought to be in the compofition. If it diffolve therein wholly and perfectly, without the appearance of the leaft little drop of oil floating on the water, it is a fign that it doth not contain too much oil. If, on the contrary, you perceive any of thefe little globules, you muft pour into the veffel containing your matter a little more of the ftrong lye, to abforb the redundant oil. If there be too much of the alkali, it may be difcovered by the tafte. If the foap leave on your tongue the fenfation of an alkaline falt, and produce an urinous favour, it is a fign that there is too much falt in proportion to the oil. In this cafe a little oil muft be added to the mixture, to faturate the fuperabundant alkali. An excefs in the quantity of alkali difcovers itfelf likewife by the foap's growing moift in the air, on being expofed to it for fome time.

Fixed alkalis, even when refolved into a liquor, that is, when loaded with much water, unite eafily with fat oils, as appears from the experiment juft recited, and require but a moderate heat to perfect that union. This combination may even be completely effected without the aid of fire, and by the heat of the fun only, provided fufficient time be allowed for that purpofe. It only requires the mixture of the oil and alkali to be kept five or fix

six days in digestion, and stirred from time to time. A lixivium of pure alkali, not acuated by lime, may also be used to make soap: but it is observed, that the combination succeeds better, and that the alkali unites sooner and more perfectly with the oil, when it is sharpened by lime.

The oil is first mixed with a weaker and more aqueous lye, to the end that the combination may not take place too hastily, but that all the particles of the two substances to be compounded together may unite equally. But as soon as the alkali begins to dissolve the oil gradually and quietly, the dissolution may then be accelerated; and that is done by adding the remaining lye, which is stronger and less diluted than the other.

Soap made with olive oil is white, hard, and hath not a very disagreeable smell: but as that oil is dear, others, even the fat and oils of animals, are sometimes substituted for it. The soaps made with most of these other matters are neither so hard, nor so white, as that made of olive oil: they are called *soft soaps*.

Oils thus associated with fixed alkalis are by that means rendered soluble in water; because the alkaline salts, having a great affinity with water, communicate part thereof to the oils with which they are now incorporated. Yet the oil is not for all that rendered thoroughly miscible with water, or perfectly soluble therein; for the water in which soap is dissolved hath always a milky cast: now there is no other criterion of a perfect solution but transparency.

Alkalis also lose part of their affinity with water, by the union they thus contract with oils: for, when the combination is properly made, they no longer attract the moisture of the air, nor doth water dissolve them in such quantities as before. The composition of soap is plainly a saturation of an alkali with an oil; and, in order to make perfect soap, we are forced, as was said in the process, to grope, in a manner, by repeated trials, for this point of saturation; just as when we prepare a neutral salt by saturating an alkali with an acid. The union which the oil contracts with the alkali makes it lose, in part, the readiness with which it naturally takes fire; because the salt is not inflammable: the water also, which enters, in pretty considerable quantities, into the composition of soap, contributes a good deal to hinder the accension of the oil.

Soap may be decompounded either by distilling it, or by mixing it with some substance that hath a greater affinity than oil with alkalis.

If we decompound it by distillation, a phlegm, or transparent spirit, of a somewhat yellowish colour, first comes over. This liquor is the aqueous part of the soap, quickened by a little of its alkali, which gives it an acrid taste. It is followed by a red oil, which at first is pretty thin and limpid, but thickens as the distillation advances, grows black, and has a very disagreeable empyreumatic smell. This oil is soluble in spirit of wine.

When the distillation is finished, that is, when the retort being kept red-hot for some time will discharge no more, there is left in it a saline mass; which is the alkali of the soap, crusted over with some of the most fixed parts of the oil, that are charred to a coal. This salt may be restored to the same degree of purity it had before its combination with the oil, by calcining it in a crucible with a naked fire, that may consume this burnt part of the oil, and reduce it to ashes.

It is plain, that the oil contained in soap is affected by distillation, much in the same manner as that which we mixed with lime and distilled.

Mr Geoffroy, by analysing soap with care, discovered that two ounces thereof contain ninety-six grains of salt of kelp, freed from all oil and moisture; or two drams and forty-eight grains of that salt, as it is used in manufacturing soap; that is, containing water enough to make it crystallise; one ounce three drams twenty grains of olive oil; and about two drams four grains of water.

As acids have a greater affinity than any other substance with alkalis, they may be very effectually employed to decompound soap.

If you propose to decompound soap by means thereof, you must first dissolve it in a sufficient quantity of water. Mr Geoffroy, who made this experiment likewise, dissolved two ounces thereof in about three gallons of warm water, and to the solution added oil of vitriol, which he let fall into it drop by drop. Every time a drop of acid falls into it, a *coagulum* is formed in the liquor. The vessel in which the solution is contained must then be shaken, that the acid may equally attack all the alkali diffused in it When no new coagulation is produced by a drop of the acid, it is a sign you have added enough. The liquor then begins to grow clear: and if another quart of water be added, in order to facilitate the separation of the oily particles, you will see them rise and unite together on the surface of the liquor.

This is a pure, clear, true olive oil, hath its taste, its smell, and, like it, is fluid in warm weather, and becomes fixed by cold. Yet it differs in some respects from that which never hath been united with an alkali in order to form a soap; for it burns more vividly and more rapidly, and is soluble in spirit of wine. We shall account for these differences when we come to treat of ardent spirits.

Not only the vitriolic acid, but all others, even those obtained from vegetables, are capable of decompounding soap, and separating the oil from the alkali. In the liquor wherein soap is thus decompounded, is found a neutral salt, consisting of the acid made use of, united with the alkali of the soap. If the vitriolic acid be used, you will have a Glauber's salt; a quadrangular nitre, if the nitrous acid be used; and so of the rest.

The facility with which acids decompound soap is the reason that no water, but what is very pure, will dissolve it, or is fit to be used in washing with it.

Water that doth not dissolve soap well is usually called hard water. Such waters contain a certain quantity of saline matters, washed out of the earths through which they pass. The hardness of water is generally occasioned by selenitic particles.

The hardness of most well-waters is owing to a considerable quantity of selenitic gypsum with which the soil abounds. The selenites are neutral salts consisting of the vitriolic acid united with an earthy basis. If, therefore, soap be put into water in which a salt of this kind is dissolved,

solved, it is evident that the vitriolic acid in the selenites, having a greater affinity with the fixed alkali of the soap than with its own earthy basis, will quit the latter to unite with the former; and thus the soap will be decompounded instead of being dissolved. Accordingly we see, that, when we attempt to dissolve soap in our well-water, the surface of the liquor is in a short time covered with a fat oily pellicle. However, this decomposition of soap is not complete; at least but a small part of it is perfectly decompounded; because the great quantity of selenites, with which the water is impregnated, hinders the soap from mixing so thoroughly with it, as is requisite to produce a total decomposition thereof.

All mineral waters are likewise hard, with regard to soap; for, as most of them owe their virtues to the efflorescencies they have washed off, from pyrites that have grown hot and begun to be decomposed, they are impregnated with the saline matters produced by pyrites in that state; that is, with aluminous, vitriolic, and sulphureous substances, which have the same effect on soap as the selenites hath.

Mineral waters containing neutral salts only, such as sea-salt, Epsom salt, Glauber's salt, are nevertheless hard with regard to soap, though the acids of those salts, being united with fixed alkalis, are incapable of decompounding it. The reason is, that those neutral salts are more soluble in water than soap is; so much indeed as even to exclude it: because each of the two principles that compose them hath a very great affinity with water; whereas only one of the principles of soap, namely, its alkali, hath that affinity; the other, *viz.* the oily principle, having none at all. Thus water impregnated with an acid, or with any neutral salt, is hard with regard to soap, and incapable of dissolving it; and hence it follows, that soap is a sort of touchstone for trying the purity of water.

Wine dissolves soap; but imperfectly, because it contains an acid or tartarous part. Spirit of wine also dissolves it: but neither is this dissolution perfect; because it contains too little water: for its spirituous part can dissolve nothing but the oil of the soap; and the alkali is not at all, or at least in a very small quantity, soluble in this menstruum. The true solvent of soap is therefore a liquor that is partly spirituous, partly aqueous, and not acid.

Brandy has these qualities: and accordingly it is the solvent that unites best with soap, dissolves the greatest quantity, and makes the most limpid solution thereof. Yet even this solution hath something of a milky cast, occasioned by its not being entirely free from an acid, or the tartarous principle. This fault may be easily corrected, by mixing with it a little alkali to absorb the acid. A dram of crystallised salt of kelp mixed with three ounces and a half of good brandy, renders it capable of dissolving an ounce and two drams of good hard soap into a perfectly limpid liquor.

Some years ago it was discovered that soap might be used with great success in medicine, and that it possesses the property of dissolving the stony concretions that form in several parts of the body, particularly in the kidneys and bladder. Soap is the basis of the composition known by the name of *Mrs Stephen's remedy*; and in this one ingredient its whole virtue resides.

From what hath been said on the nature of this compound, as well as on the cause and phenomena of its dissolution, it plainly appears to be of the last consequence, in administering it to a patient, that his constitution be considered, and a proper regimen ordered. All acids should be absolutely forbid him; as we know they hinder the soap from dissolving, and decompound it: and if the patient have any acidities in the first passages, matters capable of neutralising them should be prescribed him; as prepared crabs eyes, and other absorbents known in medicine: In such cases those with which the soap is compounded in Mrs Stephen's remedy may be of use.

To combine Fat Oils with Sulphur.

Put any fat oil whatever into an earthen vessel; add to it about a fourth part of its weight of flower of sulphur, and set the vessel in a furnace, with lighted coals under it. When the oil hath acquired a certain degree of heat, the sulphur will melt, and you will see it fall immediately to the bottom of the oil, in the form of a very red fluid. The two substances will remain thus separated, without mixing together, while the heat is no greater than is necessary to keep the sulphur in fusion. Increase it therefore; but slowly, and with circumspection, lest the matter take fire. When the oil begins to smoke, the two liquors will begin to mix and look turbid: at last they will unite so as to appear one homogeneous whole. If you keep up the heat, so that the mixture shall always continue smoking and ready to boil, you may add more sulphur, which will perfectly incorporate with it: and thus may a pretty considerable quantity thereof be introduced into this composition.

To combine Fat Oils with Lead, and the Calxes of Lead. The Basis of Plasters. The Decomposition of this Combination.

Into an earthen vessel put granulated lead, litharge, ceruse, or minium; and pour thereon twice its weight of any fat oil whatever. If you set the vessel over a brisk fire, the lead at bottom will melt before the oil begin to boil. When it boils, stir the matter with a stick: the lead, or the calx of lead, will gradually disappear, and at last be totally dissolved by the oil, to which it will give a very thick consistence.

Fat oils dissolve not only lead, but its calxes also: nay, they dissolve the latter more readily than lead in substance; probably because they are more divided. The result of a combination of these matters is a thick, tenacious mass, that grows in some degree hard in the cold, and soft by heat. This composition is known in pharmacy by the name of *plaster*. It is made up with several drugs into plasters, which partake of the virtues of those drugs; so that it is the basis of almost all plasters.

Lead itself is seldom used to make plasters: ceruse, litharge, or minium, are preferred to it; because these matters unite more readily with oils.

Of the Subſtances obtained from Vegetables with a Degree of heat not exceeding that of boiling Water.

To obtain from Plants, by diſtilling them with the mean Degree of heat between freezing and boiling Water, a Liquor impregnated with their Principle of Odour.

In the morning, before ſun-riſe, gather the plant from which you deſign to extract its odoriferous water. Chuſe the plant in its full vigour, perfectly ſound, and free from all adventitious matters, except dew. Put this plant, without ſqueezing it, into the body of a tinned copper alembic, and ſet it in a water bath. Fit on its head, and to the noſe thereof lute a glaſs receiver with wet bladder.

Warm the bath to the mean degree between freezing and boiling water. You will ſee a liquor diſtill and fall drop by drop into the receiver. Continue the diſtillation with this degree of heat, till no more drops fall from the noſe of the alembic. Then unlute the veſſels; and if you have not as much liquor as you want, take out of the cucurbit the plant already diſtilled, and put a freſh one in its place. Diſtill as before, and go on thus till you have a ſufficient quantity of odoriferous liquor. Put it into a bottle; ſtop it cloſe; and ſet it in a cool place.

The liquor obtained from plants, with the degree of heat here preſcribed, conſiſts of the dew that was on the plant, and ſome of the phlegm of the plant itſelf, together with its odorous principle. Mr Boerhaave, who examined this odoriferous part of plants with great care, calls it the *ſpiritus rector*. The nature of this ſpirit is not yet thoroughly aſcertained; becauſe it is ſo very volatile, that it cannot eaſily be ſubjected to the experiments that are neceſſary to analiſe it, and to diſcover all its properties. If the bottle containing the liquor which may be conſidered as the vehicle of this ſpirit, be not exceeding carefully ſtopped, it flies quite off: ſo that in a few days nothing will be found but an inſipid inodorous water.

Great part of the virtue of plants reſides in this their principle of odour; and to it muſt be aſcribed the moſt ſingular and the moſt wonderful effects we every day ſee produced by them. Every body knows that a great number of odorous plants affect, in a particular manner, by their ſcent only, the brain and the *genus nervoſum*, of ſuch eſpecially whoſe nerves are very ſenſible, and ſuſceptible of the ſlighteſt impreſſion; ſuch as hypochondriacal or melancholy men, and hyſterical women. The ſmell of the tuberoſe, for inſtance, is capable of throwing ſuch perſons into fits, ſo as to make them drop down and ſwoon away. The ſmell of rue again, which is equally ſtrong and penetrating, but of a different kind, is a ſpecific remedy againſt the ill effects of the tuberoſe; and brings thoſe perſons to life again, with as quick and as ſurpriſing an efficacy as that by which they were reduced to a ſtate not unlike death. This is Mr Boerhaave's obſervation.

The odorous exhalations of plants muſt be conſidered as a continual emanation of their *ſpiritus rector*: but as growing plants are in a condition to repair, every inſtant, the loſſes they ſuſtain by this means, as well as by tranſpiration, it is not ſurpriſing that they are not ſoon exhauſted while they continue in vigour. Thoſe, on the contrary, which we diſtill, having no ſuch reſource, are very ſoon entirely exhauſted of this principle.

The ſeparation of the *ſpiritus rector* from plants requires but a very gentle heat, equally diſtant from the freezing point, and from the heat of boiling water. Accordingly the heat of the ſun in ſummer is ſufficient to diſſipate it almoſt entirely. This ſhews why it is dangerous to ſtay long in fields, or woods, where many noxious plants grow. The virtues of plants reſiding chiefly in their exhalations, which the heat of the ſun increaſes conſiderably, a ſort of atmoſphere is formed round them, and carried by the air and the wind to very great diſtances.

For the ſame reaſon the air of a country may be rendered ſalutary and medicinal, by the exhalations of wholeſome plants growing therein. From the facility with which the odorous principle of plants evaporates, we learn what care ought to be taken in drying thoſe intended for medical uſes, ſo as to preſerve their virtues. They muſt by no means be expoſed to the ſun, or laid in a warm place: a cool, dry place, into which the rays of the ſun never penetrate, is the propereſt for drying plants with as little loſs of their virtue as poſſible.

Though there is reaſon to believe that every vegetable matter hath a *ſpiritus rector*, ſeeing each hath its particular ſcent, yet this principle is not very perceptible in any but thoſe which have a very manifeſt odour: and accordingly it is extracted chiefly from aromatic plants, or the moſt odoriferous parts of plants.

To extract the Fat Oils of Plants by the Decoction in boiling Water. Cacao-Butter.

Pound or bruiſe in a marble mortar your vegetable ſubſtances abounding with the fat oil which you intend to extract by decoction; tie them up in a linen cloth: put this packet into a pan, with ſeven or eight times as much water, and make the water boil. The oil will be ſeparated by the ebullition, and float on the ſurface of the water. Skim it off carefully with a ladle, and continue boiling till no more oil appear.

The heat of boiling water is capable of ſeparating the fat oils from vegetable matters that contain any: but this is to be effected by actual decoction only, and not by diſtillation; becauſe theſe oils will not riſe in an alembic with the heat of boiling water. We are therefore neceſſitated to collect them from the ſurface of the water, as above directed.

The water uſed in this coction generally becomes milky, like an emulſion. Nevertheleſs this way of obtaining the fat oils is not generally practiſed; becauſe the heat, to which they are expoſed in the operation, occaſions their being leſs mild than they generally are: but it is an excellent method, and indeed the only one that can be employed, for extracting from particular vegetables certain concrete oily matters, in the form of butter or wax; which

which matters are no other than fat oils in a fixed ftate. The cacao yields, by this means, a very mild butter; and in the fame manner is a wax obtained from a certain fhrub in America.

To extract the Effential Oils of Plants by diftillation with the heat of boiling water. Diftilled waters.

Put into a cucurbit the plant from which you defign to extract the effential oil. Add as much water as will fill two thirds of your veffel, and diffolve therein half an ounce of fea-falt for every quart of water you ufe. To this body fit on an alembic-head, and to the nofe thereof lute a receiver with fized paper or wet bladder. Set it in a furnace, and let the whole digeft together, in a very gentle warmth, for twenty-four hours.

This being done, light a wood-fire under your veffel, brifk enough to make the water in it boil immediately. Then flacken your fire, and leave it juft ftrong enough to keep the water fimmering. There will come over into the receiver a liquor of a whitifh colour, fomewhat milky; on the furface of which, or at the bottom, will be found an oil, which is the effential oil of the vegetable you put into the cucurbit. Continue your diftillation with the fame degree of heat, till you perceive the liquor come off clear and unaccompanied with an oil.

When the diftillation is finifhed, unlute the receiver; and, if the effential oil be of that fort that is lighter than water, fill the veffel up to the top with water. On this occafion a long-necked matras fhould be ufed for a receiver; that the oil which floats on the water may collect together in its neck, and rife up to its mouth. Then in the neck of this veffel put the end of a thread of cotton twine, fo that the depending part without the veffel may be longer than that in the oil, and the extremity thereof hang within the mouth of a little phial, juft big enough to contain your quantity of oil. The oil will rife along the yarn as in a fiphon, filter through it, and fall drop by drop into the little phial. When all the oil is thus come over, ftop your little bottle very clofe, with a cork coated over with a mixture of wax and a little pitch.

If your oil be ponderous, and of the fort that finks in water, pour the whole contents of the receiver into a glafs funnel, the pipe of which muft terminate in a very fmall aperture that may be ftopped with your fore-finger. All the oil will be collected in the lower part of the funnel: then remove your finger, and let the oil run out into a little bottle through another fmall funnel. When you fee the water ready to come, ftop the pipe of the funnel, and cork the bottle containing your oil.

To extract the Effential Oils of Plants by Diftillation per defcenfum.

Reduce to a powder, or a pafte, the vegetable fubftances from which you intend to extract the effential oil by the method propofed. Lay this matter about half an inch thick on a fine, clofe, linen cloth. If it be dry and hard, expofe the cloth containing it to the fteam of boiling water, till the matter become moift and foft. Then lay the cloth, with its contents, over the mouth of a very tall cylindrical glafs veffel, which is to do the office of a receiver in this diftillation; and, by means of a piece of fmall pack-thread, faften down the extremities of the cloth, by winding the thread feveral times over them and round the veffel; in fuch a manner, however, that the cloth be not tight, but may yield to a fmall weight, and fink about five or fix lines deep into the veffel over which it is faftened. Set this recipient in a larger veffel, containing fo much cold water as will reach half way up the cylindrical veffel, which, having little in it but air, muft be ballafted with as much lead as will fink it to the bottom of the water.

On the cloth, containing the fubftance to be diftilled, fet a flat pan of iron or copper, about five or fix lines deep, that may juft fit the mouth of the glafs veffel over which the cloth is faftened, fo as to fhut it quite clofe. Fill this pan with hot afhes, and on thefe lay fome live coals. Soon after this you will fee vapours defcend from the cloth, which will fill the recipient, and drops of liquor will be formed on the under fide of the cloth, from whence they will fall into the veffel. Keep up an equal gentle heat, till you preceive nothing more difcharged. Then uncover the recipient: you will find in it two diftinct liquors; one of which is the phlegm, and the other the effential oil of the fubftance diftilled.

Infufions, Decoctions, and Extracts of Plants.

Make fome water boiling-hot, and then take it off the fire. When it ceafes to boil, pour it on the plant of which you defire to have the infufion; taking care there be enough of it to cover the plant entirely. Cover the veffel, and let your plant lie in the hot water for the fpace of half an hour, or longer if it be of a firm clofe texture. Then pour off the water by inclination: it will have partly acquired the colour, the fmell, the tafte, and the virtues of the plant. This liquor is called an *infufion*.

To make the decoction of a vegetable fubftance, put it into an earthen pan, or into a tinned copper veffel, with a quantity of water fufficient to bear being boiled for feveral hours without leaving any part of the plant dry. Boil your plant more or lefs according to its nature; and then pour off the water by inclination. This water is impregnated with feveral of the principles of the plant.

If the infufions and decoctions of plants be filtered, and evaporated in a gentle heat, they become extracts, that may be kept for whole years, efpecially if they be evaporated to a thick confiftence; and better ftill if they be evaporated to drynefs.

Of Operations on Effential Oils.

The Rectification of Effential Oils.

Put into a cucurbit the effential oil you propofe to rectify. Set the cucurbit in a *balneum mariæ*; fit to it a head of tin, or of copper tinned, together with its refrigeratory; and lute on a receiver. Make the water in the bath boil, and keep up this degree of heat till nothing more will come over. When the diftillation is finifhed,

nished, you will find in the receiver a rectified essential oil, which will be clearer, thinner, and better scented than before it was thus before re-distilled; and in the bottom of the cucurbit will be left a matter of a deeper colour, more tenacious, more resinous, and of a less grateful smell.

Essential oils, even the purest, the best prepared, and the thinnest, suffer great changes, and are much impaired by growing old: they gradually turn thick and resinous; their sweet, grateful scent is lost, and succeeded by a more disagreeable smell, somewhat like that of turpentine. The cause of these changes is, that their finest and most volatile part, that which contains most of the odorous principle, is dissipated and separated from that which contains least of it; which therefore grows thicker, and comes so much the nearer to the nature of a resin, as the quantity of acid, that was distributed through the whole oil before the dissipation of the more volatile part, is, after such dissipation, united and concentrated in the heaviest part; the acid in oils being much less volatile than the odorous part, to which alone they owe their levity.

Hence it appears what precautions are to be used for preserving essential oils as long as possible without spoiling. They must be kept in a bottle perfectly well stopped, and always in a cool place, because heat quickly dissipates the volatile parts. Some authors direct the bottle to be kept under water.

To fire Oils by combining them with highly concentrated Acids: instanced in Oil of Turpentine.

Mix together in a glass equal parts of concentrated oil of vitriol, and highly smoking fresh-drawn spirit of nitre: pour this mixture at several times, but suddenly, on three parts of oil of turpentine, set for that purpose in a glass bason. By a part here must be understood a dram at least. A most violent commotion, accompanied with smoke, will immediately be raised in the liquors, and the whole will take fire in an instant, flame, and be consumed.

There is not in chemistry a phenomenon more extraordinary, and more surprising, than the firing of oils by mixing them with acids. It could never have been suspected, that a mixture of two cold liquors would produce a sudden, violent, bright, and lasting flame, like that we are at present considering.

To combine Essential Oils with Mineral Sulphur. Balsam of Sulphur.

Put into a matras one part of flowers of sulphur; pour on them six parts of the essential oil of turpentine, for instance; set the matras in a sand-bath, and heat it gradually till the oil boil. The sulphur, which at first lay at the bottom of the matras, will begin to melt, and appear to dissolve in the oil. When it hath boiled in this manner for about an hour, take the matras from the fire, and let the liquor cool. A great deal of the sulphur that was dissolved therein will separate from it as it cools, and fall to the bottom of the vessel in the form of needles, much like a salt shooting in water.

When the liquor is perfectly cold, decant it from the sulphur that lies at the bottom of the vessel: to that sulphur put fresh oil of turpentine, and proceed as before: the sulphur will again disappear, and be dissolved in the oil; but when the mixture is cold you will find new crystals of sulphur deposited at the bottom. Decant once more this oil from the crystals, and pour on fresh oil to dissolve them: continue the same method, and you will find, that about sixteen parts of essential oil are required to keep one part of sulphur dissolved when cold. This combination is called *balsamum sulphuris terebinthinatum*, if made with oil of turpentine; *anisatum*, if with oil of anise-seeds; and so of others.

To combine Essential Oils with fixed Alkalis. Starkey's Soap.

Take salt of tartar, or any other alkali, thoroughly calcined. Heat it in a crucible till it be red, and in that condition throw it into a hot iron mortar: rub it quickly with a very hot iron pestle; and as soon as it is powdered, pour on it, little by little, nearly an equal quantity of oil of turpentine. The oil will enter into the salt, and unite intimately with it, so as to form a hard paste. Continue rubbing this composition with a pestle, in order to complete the union of the two substances; and, as your oil of turpentine disappears, add more, which will unite in the same manner, and give a softer consistence to the soapy mass. You may add still more oil, according to the consistence you intend to give your soap.

Starkey, the first chemist who found the means of making soap with an essential oil, and by whose name this kind of soap is therefore called, made use of a much more tedious method than that proposed in our process. He began with mixing a very small quantity of oil with his salt, and waited till all the oil united therewith of its own accord, so as to disappear entirely, before he added any more; and thus protracted his operation exceedingly, though in the main it was the same with ours. The method here proposed is more expeditious, and was invented by Dr Geoffroy.

Starkey's soap dissolves in water much as common soap does, without any separation of the oil: and by this mark it is known to be well made. It may also be decompounded, either by distillation, or by mixing it with an acid: and its decomposition, in either of these ways, is attended with nearly the same phenomena as the decomposition of common soap.

Of the Substances obtained from Vegetables by means of a graduated Heat, from that of boiling Water, to the strongest that can be applied to them in close Vessels.

To analise Vegetable Substances that yield neither a Fat nor an Essential Oil. Instanced in Guaiacum-wood.

Take thin shavings of Guaiacum-wood, and put them into a glass or stone retort, leaving one half thereof empty. Set your retort in a reverberating furnace, and lute on a large glass receiver having a small hole drilled in it, such as is used for distilling the mineral acids. Put a live

live coal or two in the furnace, to warm the veſſels gently and ſlowly.

With a degree of heat below that of boiling water, you will ſee drops of a clear inſipid phlegm fall into the receiver. If you raiſe the fire a little, this water will come ſlightly acid, and begin to have a pungent ſmell. With a degree of fire ſomewhat ſtronger, a water will continue to riſe which will be ſtill more acid, ſmell ſtronger, and become yellowiſh. When the heat comes to exceed that of boiling water, the phlegm that riſes will be very acid, high coloured, have a ſtrong pungent ſmell, like that of matters long ſmoked with wood in a chimney, and will be accompanied with a red, light oil, that will float on the liquor in the receiver.

And now it is neceſſary, that the operation be carried on very cautiouſly, and vent frequently given to the rarefied air by opening the ſmall hole in the receiver; ſuch an incredible quantity thereof ruſhing out of the wood, with this degree of heat, as may burſt the veſſels to pieces, if not diſcharged from time to time.

When this red, light oil is come over, and the air ceaſes to ruſh out with impetuoſity, raiſe your fire gradually, till the retort begin to redden. The receiver will be filled with denſe vapours; and together with the watery liquor, which will then be extremely acid, there will riſe a black, thick, ponderous oil, which will fall to the bottom of the receiver and lie under the liquor.

Then give the utmoſt degree of heat; that is, the greateſt your furnace will allow, and your veſſels bear. With this exceſſive heat a little more oil will riſe, which will be very ponderous, as thick and black as pitch; and the veſſels will continue full of vapours that will not condenſe.

At laſt, when you have kept the retort exceeding red for a long time in this extremity of heat, ſo that it begins to melt if it be of glaſs, and you perceive nothing more come over, let the fire go out and the veſſel cool. Then take off your receiver: from the black oil at bottom decant the acid liquor with the red oil floating on it, and pour them both into a glaſs funnel, lined with brown filtering paper, and placed over a bottle. The acid liquor will paſs through the filter into the bottle, and the oil will be left behind, which muſt be kept by itſelf in a ſeparate bottle. Laſtly, into another funnel, prepared as the former, pour the thick oil remaining with a little of the acid liquor at the bottom of the receiver. This liquor will filter off in the ſame manner, and thus be ſeparated from the heavy oil.

In the retort you will find your Guaiacum ſhavings not in the leaſt altered as to their figure, but light, friable, very black, ſcentleſs and taſteleſs, eaſily taking fire, and conſuming without flame or ſmoke: in ſhort you will find them charred to a perfect coal.

Hitherto we have examined the ſubſtances that may be obtained from vegetables, either without the help of fire, or with a degree of heat not exceeding that of boiling water. The analyſis of plants can be carried no further without a greater degree of heat: for, when the principle of odour and the eſſential oil of an aromatic plant are wholly extracted by the preceding proceſſes, if the diſtillation be afterward continued without increaſing the heat, nothing more will be obtained but a little acid; which will ſoon ceaſe, as a ſmall part only of the quantity contained in the plant will be elevated; the reſt being either too ponderous, or too much entangled with the other principles of the body, to riſe with ſo ſmall a degree of heat.

In order therefore to carry on the decompoſition of a plant, from which you have, by the methods before propoſed, extracted all the principles it is capable of yielding when ſo treated; or, in order to analiſe a vegetable matter, which affords neither an expreſſed nor an eſſential oil, it muſt be diſtilled in a retort with a naked fire, as directed in the proceſs, and be made to undergo all the degrees of heat ſucceſſively, from that of boiling water to the higheſt that can be raiſed in a reverberating furnace.

A heat inferior to that of boiling water, with which we muſt begin in order to warm the veſſel gradually, brings nothing over, but an inſipid water, deſtitute of all acidity. By increaſing it nearly to the degree of boiling water, the diſtilled water comes to be ſlightly acid.

When the heat is made a little ſtronger than that which is neceſſary for the elevation of an eſſential oil, the acidity of the water that comes off is much more conſiderable. It hath now both colour and ſmell, and there riſes with it a red, light oil, that floats on the liquor in the receiver. This is not an eſſential oil; it hath none of the odour of the plant. Though ſo light as to float on water, yet it will not riſe with the degree of heat that raiſes eſſential oils, even thoſe that much ſurpaſs it in gravity, and will not ſwim on water as they do. This proves, that the eaſe or difficulty with which a particular degree of heat raiſes any ſubſtance in diſtillation doth not depend altogether on its gravity: its dilatability, or the volatile nature of the matters with which it is ſo cloſely united as not to be ſeparated from them by diſtillation, may probably contribute greatly to produce this effect.

It is very ſurpriſing, that a ſubſtance ſo hard, ſo compact, ſo dry in appearance, as Guaiacum-wood, ſhould yield ſuch a large quantity of water by diſtillation; and it is equally ſo, that it ſhould diſcharge ſo much air, and with ſo much impetuoſity, as nothing but experience could render credible.

It hath been remarked, that the heavieſt and moſt compact woods yield the moſt air in diſtillation: and accordingly Guaiacum-wood, as exceeding almoſt all others in hardneſs and weight, diſcharges a vaſt quantity of air when analiſed.

The thick, burnt, empyreumatic oil, that comes over laſt in this diſtillation, is heavier than water; on account, probably, of the great quantity of acid with which it is replete. The two kinds of oil obtained in this analyſis may be rectified, by diſtilling them a ſecond time, or rather ſeveral times; by which means they will become lighter and more fluid. In general, all thick, heavy oils conſtantly owe theſe qualities to an acid united with them; and it is by being freed from ſome of that acid in diſtillation, that they always acquire a greater

er degree of lightnefs and fluidity from that operation.

The analyfis of a vegetable fubftance, fhews what may be obtained from them when diftilled in clofe veffels, with a graduated heat, from that of boiling water, to that which converts the mixt to a perfect coal; viz. phlegm, an acid, a light oil, much air, and a thick oil. But this analyfis is far from being a complete one: it may be carried much farther, and made more perfect.

None of the principles obtained by this analyfis are pure, fimple, and thoroughly feparated from the reft. They are ftill in fome meafure blended all together: their feparation is but begun; and each requires a fecond and more accurate analyfis, to reduce it to the greateft degree of purity of which it is capable. The oil and the acid chiefly merit fo much pains.

A great deal of the acid of the plant remains, combined with the two forts of oil here obtained; which we have reafon to think differ no otherwife from one another, than as there is more or lefs acid united with each. The beft way of freeing thefe oils from their redundant acid is to diftill them frequently from alkalis and abforbents.

The acid is in the fame circumftances nearly as the oil. The firft that rifes is mortified with much water, to which it owes a good deal of its volatility. That which comes over laft is much more concentrated, and confequently heavier; yet it is ftill very aqueous. It might be freed in a great meafure from this adventitious water, and fo rendered much ftronger; which would give us a better opportunity to difcover its nature and properties, of which we know but very little.

Water is not the only heterogeneous fubftance that difguifes the vegetable acid: a pretty confiderable quantity of the oil of the plant is alfo combined with it, and contaminates its purity. The proof of this is, that when thefe acids are kept, in the fame condition in which they firft come over, for any length of time, in a glafs veffel, they gradually depofite, on the bottom and fides of the veffel, an oily incruftation, which grows thicker and thicker the longer it ftands; and, as this oily matter feparates from it, the acid liquor appears lefs unctuous and faponaceous.

A very good way to feparate this oil more effectually from the acid is to combine the whole with abforbents, and abftract the oil again by diftillation. By this means a very fenfible quantity of oil may be feparated that was not perceived before.

The air, that is difcharged with impetuofity in the operation, and muft be let out, is loaded with many particles of acid and oil reduced to vapours, which it carries off; and by this means the quantity of the principles extracted from the mixt cannot be accurately determined: nor are the vapours, of which the veffels remain full after the operation, any other than particles of acid and oil, which the violence of the fire hath rarefied exceedingly, and which do not eafily condenfe.

If we diftill in this manner a vegetable aromatic fubftance, which of courfe contains an effential oil, provided it hath not been previoufly extracted by the appropriated procefs, this effential oil will rife firft, as foon as the diftilling veffel acquires the heat of boiling water: but its fcent will not be near fo fweet or grateful, as if it were diftilled in the manner before directed as propereft for it. On the contrary, it will have an empyreumatic fmell: becaufe in this way it is impoffible to avoid fcorching, and half-burning fome of the matter diftilled; efpecially that part of it which touches the fides of the retort. Moreover, the very fame equable degree of heat can hardly be kept up with a naked fire. The effential oil therefore, though it rifes firft, will not be pure, but contaminated with a mixture of the empyreumatic oil that firft comes over, and will be confounded therewith.

Moft vegetable fubftances, when diftilled with a ftrong fire, yield the fame principles with that which we have chofen for an inftance. Entire plants of this kind, thofe from which the odorous principle, the effential oil, or the fat oil, hath been drawn, thofe of which extracts have been made by infufion or decoction, or the extracts themfelves; all fuch matter being diftilled yield a phlegm, an acid, a thin oil, air, and a thick oil; and the products of their feveral analyfes differ from each other, only on account of the different quantity or proportion that each contains of the principles here enumerated.

But there are many other plants, which, befides thefe fubftances, yield alfo a confiderable quantity of a volatile alkaline falt. This property is poffeffed chiefly by that tribe of plants which is diftinguifhed by having cruciform flowers: among which there are fome that, being analifed, greatly refemble animal-matters. We fhall now analife one of thefe; muftard-feed, for inftance.

To analife a Vegetable Subftance which yields the fame Principles as are obtained from Animal-matters: inftanced in Muftard-feed.

With an apparatus like that of the preceding procefs, and with the fame fire, diftill muftard-feed. With a degree of heat, inferior to that of boiling water, there will come over a phlegm fomewhat coloured, and impregnated with a volatile alkaline falt. With a degree of heat, greater than that of boiling water, the fame kind of phlegm, impregnated with the fame falt, will continue to come over; but it will be much higher coloured, and will be accompanied with a light oil. At this time a confiderable quantity of air is difcharged; with regard to which the fame precautions muft be taken as in diftilling Guaiacum.

If the fire be gradually raifed, there will come over a black thick oil, lighter however than water; and at the fame time vapours will rife, and, condenfing on the fides of the receiver, form into fprings or ramifications. This is a volatile alkaline falt, in a concrete form, like that of animals, as we fhall hereafter fee. Thefe vapours are much whiter than thofe of Guaiacum.

When you have thus drawn off, with a very ftrong fire, all the volatile alkali and thick oil contained in the fubject, there will be nothing left in the retort but a fort of coal, from which a fmall quantity of phofphorus may be obtained, provided the retort you employ for that purpofe be good enough to ftand a very violent heat.

Muftard-feed furnifhes us with an inftance of a vegetable, from which we obtain, by analifing it, the very fame principles that animal-matters yield. Inftead of

of getting an acid from it, we obtain only a volatile alkali.

We ſhall not here ſpeak of the manner of ſeparating and depurating the principles obtained by this proceſs; but reſerve it for the analyſis of animals, which is abſolutely the ſame. We ſhall content ourſelves with obſerving, that the firſt volatile alkali, which riſes at the beginning of the operation together with the phlegm, in a degree of heat below that of boiling water, differs from that which doth not come over till towards the end of the diſtillation, when the laſt thick oil aſcends. The different times, and different degrees of heat, in which theſe two alkalis riſe, ſhew that the former exiſts actually and perfectly in the plant; but that the latter is generated during the diſtillation, and is the product of the fire, which combines together the materials whereof it is compoſed.

Vegetables, that thus yield a volatile alkali with a heat leſs than that of boiling water, irritate the organ of ſmelling, affecting it with a ſenſation of acrimony; and the effluvia, which riſe from them when bruiſed, make the eyes ſmart ſo as to draw tears from them in abundance. Several of theſe matters, being only bruiſed, effervefce with acids: effects producible only by a very volatile alkaline principle.

This is that alkali, the lighteſt of all the principles that can be extracted from bodies, which riſes firſt in our diſtillation along with the phlegm, and with a degree of heat much inferior to that of boiling water. As the phlegm with which it riſes is very copious, it is diſſolved thereby; which is the reaſon it doth not appear in a concrete form. To this water it gives a ſlight yellowiſh tinge, becauſe it is impure and oily. The ſaline alkaline properties of this liquor have procured it the title of a volatile ſpirit. This volatile alkali, which exiſts naturally and perfectly formed in muſtard-ſeed, onions, garlick, creſſes, and other ſuch vegetables, conſtitutes a difference between them and animal ſubſtances, which contain only the materials requiſite to form a volatile alkali, but none ready formed, unleſs they have undergone the putrid fermentation.

The ſecond volatile alkali, which riſes in our diſtillation, but not without a very ſtrong degree of fire, and at the ſame time with the laſt thick oil, ſeems to be a production of the fire; for, if it were already formed in the mixt, as the other is, it would riſe with the ſame heat, and at the ſame time, being equally volatile.

Of the Subſtances obtained from Vegetables by Combuſtion.

To procure a fixed Cauſtic Alkaline Salt from a Vegetable Subſtance, by burning it in the open Air.

Take any vegetable matter whatever; ſet it on fire, and let it burn in the open air till it be wholly reduced to aſhes. On theſe aſhes pour a quantity of boiling water ſufficient to drench them thoroughly. Filter the liquor, in order to ſeparate the earthy parts; and evaporate your lye to dryneſs, ſtirring it inceſſantly; and you will have a yellowiſh-white ſalt.

Put this ſalt in a crucible; ſet it in a melting furnace, and make a moderate fire, ſo as not to fuſe the ſalt. It will turn firſt of a blue-grey colour, afterwards of a blue-green, and at laſt reddiſh. Put on the dome of the furnace; fill it with coals; make your fire ſtrong enough to melt the ſalt, and keep it in fuſion for an hour, or an hour and half. Then pour it into a heated metal mortar; pound it while it is red-hot; put it as ſoon as poſſible into a glaſs bottle, firſt made very hot and dry, and ſhut it up cloſe with a glaſs ſtopple rubbed with emery. By this means you will have the pure fixed alkali of the vegetable ſubſtance you burnt.

Burning a vegetable ſubſtance in the open air is a kind of violent and rapid analyſis made by fire, which ſeparates, reſolves, and decompoſes ſeveral of its principles.

When any wood or plant is laid on a quick fire, there aſcends from it immediately an aqueous ſmoke, which conſiſts of little more than phlegm; but this ſmoke ſoon becomes thicker and blacker; it is then pungent, draws tears from one's eyes, and excites a cough if drawn into the lungs with the breath. Theſe effects ariſe from its being replete with the acid, and ſome of the oil, of the vegetable converted into vapours. Soon after this the ſmoke grows exceeding black and thick; it is now ſtill more acrid, and the plant turns black. Its ſtrongeſt acid and laſt thick oil are now diſcharged with impetuoſity.

This rarefied oil being heated red-hot ſuddenly takes fire and flames. The vegetable burns and deflagrates rapidly, till all its oil is conſumed. Then the flame ceaſes; and nothing remains but a coal, like that found in a retort after all the principles of a plant have been extracted by the force of fire. But this coal having a free communication with the air, which is abſolutely neceſſary to keep a combuſtible burning, continues to be red, ſparkles, and waſtes till all its phlogiſton is diſſipated and deſtroyed. After this nothing remains but the earth and fixed ſalt of the vegetable; which, mixed together, form what we call the aſhes. Water, which is the natural ſolvent of ſalts, takes up every thing of that kind that is contained in the aſhes; ſo that by lixiviating them, as directed, all the ſalt is extracted, and nothing left but the pure earth of the mixt which is thus decompoſed.

The phenomena obſerved in the burning of a vegetable ſubſtance, and the production thereby of a fixed alkali, ſeem to prove that this ſalt is the work of the fire; that it did not exiſt in the plant before it was burnt; that the plant only contained materials adapted to form this ſalt; and that this ſalt is no other than a combination of ſome of the acid, united with a portion of earth, by means of the igneous motion.

The alkali obtained from the aſhes of burnt plants is not perfectly pure: it is contaminated with a ſmall mixture of fatty matters, which were probably defended thereby againſt the action of the fire, and which render it ſomewhat ſaponaceous. In order to free it from this extraneous matter, and to render it very cauſtic, it muſt be calcined a long time in a crucible, but without melting it at firſt; becauſe it is with this ſalt as with moſt metallic matters, which are ſooner and more eaſily deprived of their phlogiſton by being calcined without melting, provided they be comminuted into ſmall particles, than when they are in fuſion; all melted matters having but a

a ſmall ſurface expoſed to the air, by the contact of which the evaporation of any thing whatever is exceedingly promoted.

To procure the fixed Salt of a Plant, by burning it after the manner of Tachenius.

INTO an iron pot put the plant whoſe ſalt you deſire to obtain in the manner of Tachenius. and ſet it over a fire, ſtrong enough to make its bottom red-hot; at the ſame time cover your plant with a plate of iron, that may lie immediately upon it in the pot. The plant will grow black, and ſmoke conſiderably; but will not flame, becauſe it hath not a ſufficient communication with the air. The black ſmoke only will eſcape through the interſtice left between the ſide of the pot and the rim of the plate; which, for that purpoſe, ſhould be made ſo as not to fit exactly into the pot. From time to time take up the iron plate, ſtir the plant, and cover it again immediately, to prevent its taking fire, or to ſmother it if it ſhould happen to flame: go on thus till the black ſmoke ceaſe.

Then take off the iron plate: the upper part of the half-burnt plant will take fire as ſoon as the air is admitted, conſume gradually, and be reduced to a white aſh. Stir your matter with an iron wire, that the undermoſt parts, which are ſtill black, may be ſucceſſively brought uppermoſt, take fire, and burn to white aſhes.

Go on thus as long as you perceive the leaſt blackneſs remaining. After this, leave your aſhes ſome time longer on the fire; but ſtir them frequently, to the end that, if any black particles ſhould ſtill be left, they may be entirely conſumed.

Your aſhes being thus prepared, lixiviate them with ſeven times their quantity of water, made to ſimmer over the fire, and keep ſtirring it with an iron ladle. Then filter the liquor, and evaporate it to dryneſs in an iron pot, ſtirring it inceſſantly towards the end, leſt the matter, when it grows ſtiff, ſhould adhere too cloſely to the veſſel. When all the humidity is evaporated. you will have a ſalt of a darkiſh colour and alkaline nature; which you may melt in a crucible, and mould into cakes. This is the fixed ſalt of plants, prepared in the manner of Tachenius.

To render Fixed Alkalis very cauſtic by means of Lime. The Cauſtic Stone.

TAKE a lump of newly burnt quick-lime, that hath not yet begun to ſlake in the air: put it into a ſtone pan, and cover it with twice its weight of the unwaſhed aſhes of ſome plant that are full of the ſalt you deſign to render cauſtic. Pour on them a great quantity of hot water; let them ſteep in it five or ſix hours, and then boil them gently. Filter the liquor through a thick canvas bag, or through brown filtering paper ſupported by a linen cloth.

Evaporate the filtered liquor in a copper baſon ſet over the fire; and there will remain a ſalt, which muſt be put into a crucible ſet in the fire. It will melt, and boil for ſome time; after which it will be ſtill, and look like an oil, or melted fat. When it comes to this condition, pour it out on a very hot copper plate, and cut it into oblong tapering ſlips, before it grow hard by cooling. Put theſe ſlips, while they are ſtill hot, into a very dry glaſs bottle, and ſeal it hermetically. This is the *cauſtic ſtone*, or *common cauſtic*.

The Analyſis of Soot.

TAKE wood-ſoot from a chimney under which no animal matter hath been dreſſed or burnt: put it into a glaſs retort ſet in a reverberating furnace; lute on a receiver, and begin to diſtill with a degree of heat ſomewhat leſs than that of boiling water. A conſiderable quantity of limpid phlegm will come over. Keep the fire in the ſame degree as long as any of this phlegm riſes, but increaſe it when the drops begin to come ſlow; and then there will aſcend a good deal of a milky water. When this water ceaſes to run, change the receiver, and increaſe your fire a little: a yellow volatile ſalt will riſe, and ſtick to the ſides of the receiver. The fire ought now to be very fierce, and, if ſo, will force up at the ſame time a very thick black oil. Let the veſſels cool: you will find a ſaline matter riſen into the neck of the retort, which could not paſs over into the receiver: in the bottom of the retort will be a *caput mortuum*, or black charred ſubſtance, the upper part of which will be cruſted over with a ſaline matter, like that in the neck of the retort.

As we are at preſent inquiring into the nature of vegetables only, it is evidently neceſſary that we chuſe a ſoot produced by burning vegetables alone. Soot, though dry in appearance, contains nevertheleſs much humidity, as appears from this analyſis; ſeeing there comes over at firſt a conſiderable quantity of phlegm, that doth not ſeem to be impregnated with any principle, except perhaps an extremely ſubtile, ſaline, and oily matter, that communicates to it a diſagreeable ſmell, from which it cannot by any means be entirely freed.

The volatile alkali obtained from ſoot is, in a double reſpect, the product of the fire. In the firſt place, though it derives its origin wholly from wood, or other vegetables, which, when diſtilled in cloſe veſſels, yield no volatile alkali at all, yet it produces ſuch a ſalt when analyſed in the preſent manner: whence it muſt be inferred, that the principles of thoſe vegetables are metamorphoſed into a volatile alkali, by being burnt in the open air, and ſublimed in the form of ſoot. Secondly, though ſoot, when analyſed, yields a great deal of this ſalt, yet this ſalt doth not formally pre-exiſt therein; for it doth not riſe till after the phlegm, nor without a very conſiderable degree of heat: therefore ſoot contains only the materials neceſſary to form this ſalt; therefore the perfect combination of this ſalt requires that the force of fire be applied a ſecond time; therefore it is, as was ſaid, doubly the product of the fire.

The ſaline matter which we find ſublimed into the neck of the retort, and which alſo forms the cruſt that covers the *caput mortuum* of the ſoot, appears by all chemical trials to be an ammoniacal ſalt; that is, a neutral ſalt, conſiſting of an acid and a volatile alkali. This ammoniacal ſalt riſes only into the neck of the retort, and doth not come over into the receiver; becauſe it is but ſemi-volatile. We ſhall treat more at large of the production

production of a volatile alkali, and of this ammoniacal ſalt, when we come to the analyſis of animals, and the article of ſal ammoniac.

The Analyſis of ſome particular Subſtances belonging to the Vegetable Kingdom.

Analyſis of the natural Balſams: inſtanced in Turpentine.

INTO a cucurbit put as much rain-water as will fill about a fourth part of its cavity, and pour into it the turpentine you intend to analyſe. Cover the cucurbit with its head, and lute it on with ſlips of ſized paper or wet bladder. Set your alembic in a ſand-heat; lute on a long-necked receiver; and give a gradual fire till the water in the cucurbit boil. There will come over into the receiver a good deal of phlegm, which, by little and little, will become more and more acid; and at the ſame time there will riſe a great quantity of an æthereal oil, extremely light, fluid, and as limpid and colourleſs as water.

When you obſerve that no more oil comes off, unlute your veſſels; and in the receiver you will find an acidulated water, and the æthereal oil floating on it. Theſe two liquors may be eaſily ſeparated from each other, by means of a glaſs funnel.

In the cucurbit will be left ſome of the water you put in, together with the remainder of your turpentine; which, when cold, inſtead of being fluid, as it was before diſtillation, will be ſolid, and of the conſiſtence of a reſin, and is then called *roſin*.

Put this reſiduum into a glaſs retort, and diſtill it in a reverberatory with a naked fire, gradually increaſed according to the general rule for all diſtillations. At firſt, with a degree of heat a little greater than that of boiling water, you will ſee two liquors come over into the recipient; one of which will be aqueous and acid, the other will be a tranſparent, limpid, yellowiſh oil, floating on the acid liquor.

Continue your diſtillation, increaſing your fire from time to time, by ſlow degrees. Theſe two liquors will continue to come off together; and the nearer the operation draws to its end, the more acid will the aqueous liquor become, and the thicker and deeper coloured will the oil grow. At laſt the oil will be very thick, and of a deep reddiſh yellow colour. When nothing more aſcends, unlute your veſſels: in the retort you will find only a very ſmall quantity of a charred, light, friable ſubſtance.

All natural balſams, as well as turpentine, are oily, aromatic matters, which flow in great quantities from the trees containing them, either ſpontaneouſly, or thro' inciſions made on purpoſe. As theſe matters have a ſtrong ſcent, it is not ſurpriſing that they ſhould greatly abound with eſſential oils. They may even be conſidered as eſſential oils, that naturally, and of their own accord, ſeparate from the vegetables in which they exiſt.

Natural balſams, and eſſential oils grown thick with age, are exactly one and the ſame thing. Accordingly we ſee that fire and diſtillation produce the ſame effects on both. The rectification of an eſſential oil, thickened by keeping, is nothing but a decompoſition thereof, by ſeparating, with the heat of boiling water, all thoſe parts that are light enough to riſe with that degree of heat, from what is ſo loaded with acid as to remain fixed therein.

The newer natural balſams are, the thinner they are, and the more eſſential oil do they yield; and this eſſential oil, like all others, grows thick in time, and at laſt turns again to an actual balſam.

Theſe balſams, by being long expoſed to the heat of the ſun, acquire ſuch a conſiſtence as to become ſolid. They then take another name, and are called *reſins*. Reſins yield much leſs eſſential oil when diſtilled, than balſams do. Hence it follows, that reſins are to balſams, what balſams are to eſſential oils.

The Analyſis of Reſins: inſtanced in Benjamin. The Flowers and Oil of Benjamin.

INTO a pretty deep earthen pot, having a border or rim round its mouth, put the benjamin you intend to analyſe. Cover the pot with a large conical cap of very thick white paper, and tie it on under the rim. Set your pot in a ſand-bath, and warm it gently till the benjamin melt. Continue the heat in this degree for an hour and half. Then untie the paper cap and take it off, ſhaking it as little as poſſible. You will find all the inſide of the cap covered with a great quantity of beautiful, white, ſhining flowers, in the form of little needles. Bruſh them off gently with a feather, put them into a bottle, and ſtop it cloſe.

As ſoon as you take off the firſt cap, cover your pot immediately with a ſecond like the former. In this manner go on till you perceive the flowers begin to grow yellowiſh; and then it is proper to deſiſt.

The matter left in the pot will be blackiſh and friable when cold. Pulveriſe it; mix it with ſand; and diſtill it in a glaſs retort with a graduated heat. There will come over a light oil, of a fragrant ſcent, but in very ſmall quantity; a little of an acid liquor, and a great quantity of a red thick oil. There will be left in the retort a charred, ſpungy ſubſtance.

Of the Nature and Properties of Camphor.

WE do not propoſe to give an analyſis of this ſingular body; becauſe hitherto there is no proceſs known in chemiſtry by which it can be decompoſed. We ſhall therefore content ourſelves with reciting its principal properties, and making a few reflections on its nature.

Camphor is an oily concrete ſubſtance; a kind of reſin, brought to us from the iſland of Borneo, but chiefly from Japan. This ſubſtance reſembles reſins, in being inflammable, and burning much as they do; it is not ſoluble in water, but diſſolves entirely and perfectly in ſpirit of wine; it is eaſily ſeparated again from this menſtruum, as all other oily matters are, by the addition of water; it diſſolves both in expreſſed and in diſtilled oils; it hath a very ſtrong aromatic ſmell. Theſe are the chief

chief properties which camphor poſſeſſes in common with reſins: but in other reſpects it differs totally from them; eſpecially in the following particulars.

Camphor takes fire and flames with vaſtly more eaſe than any other reſin. It is ſo very volatile, that it vaniſhes entirely in the air, without any other heat than that of the atmoſphere. In diſtillation it riſes entire, without any decompoſition, or even the leaſt alteration. It diſſolves in concentrated mineral acids; but with circumſtances very different from thoſe that attend other oily or reſinous ſubſtances. The diſſolution is accompanied with no efferveſcence, no ſenſible heat; and conſequently can produce no inflammation. Acids do not burn, blacken, or thicken it, as they do other oily matters; on the contrary, it becomes fluid, and runs with them into a liquor that looks like oil.

Camphor doth not, like other oily matters, acquire a diſpoſition to diſſolve in water by the union it contracts with acids; though its union with them ſeems to be more intimate than that of many oily matters with the ſame acids. On the contrary, if a combination of camphor and an acid be diluted with water, theſe two ſubſtances inſtantly ſeparate from each other: the acid unites with the water, and the camphor, being entirely diſengaged from it, ſwims on the ſurface of the liquor. Neither volatile alkalis, nor the moſt cauſtic fixed alkalis, can be brought into union with it; for it always eludes their power.

Notwithſtanding theſe wide differences between camphor and all other oily and reſinous ſubſtances, the rule, that acids thicken oils, ſeems to be ſo univerſal, and ſo conſtantly obſerved by nature, that we cannot help thinking this ſubſtance, like all the reſt, is an oil thickened by an acid. But what oil? what acid? and how are they united? This is a ſubject for very curious inquiries.

With a yellow oil drawn from wine, and an acid vinous ſpirit, Mr Hellot made a kind of artificial camphor; a ſubſtance having the odour, ſavour, and inflammability of camphor; an imperfect camphor. True camphor hath the levity, the volatility, and the inflammability of æther. Can it be a ſubſtance of the ſame nature with æther, a kind of ſolid æther, an æther in a concrete form?

The Analyſis of Bitumens: inſtanced in Amber. The Volatile Salt and Oil of Amber.

Into a glaſs retort put ſome ſmall bits of amber, ſo as to fill but two thirds of the veſſel. Set your retort in a furnace covered with its dome; fit on a large glaſs receiver; and beginning with a very gentle heat, diſtill with degrees of fire. Some phlegm will firſt come off, which will gradually grow more acid, and be ſucceeded by a volatile ſalt, figured like fine needles, that will ſtick to the ſides of the receiver.

Keep the fire up to this degree, in order to drive over all the ſalt. When you perceive that little or none riſes, change the receiver, and increaſe your fire a little. A light, clear, limpid oil will aſcend. As the diſtillation advances, this oil will grow higher coloured, leſs limpid, and thicker; till at laſt it will be opaque, black, and have the conſiſtence of turpentine.

When you perceive that, though the retort be red-hot, nothing more comes off, let the fire go out. You will have in the retort a black, light, ſpungy coal. If you have taken care to ſhift the receiver, from time to time, during the diſtillation of your oil, you will have ſundry ſeparate portions thereof, each of which will have a different degree of tenuity or thickneſs, according as it came over at the beginning, or towards the end of the diſtillation.

The ſubſtance of which we have here given the analyſis, together with all others of the ſame, that is, of the bituminous kind, is, by moſt chemiſts and naturaliſts, claſſed with minerals: and ſo far they are right, that we actually get theſe mixts, like other minerals, out of the bowels of the earth, and never procure them immediately from any vegetable or animal compound. Yet we have our reaſons for acting otherwiſe, and for thinking that we could not, in this work, place them better, than immediately after thoſe vegetable ſubſtances which we call *reſins*.

Several motives determine us to proceed in this manner. The analyſis of bitumens demonſtrates, that, with regard to the principles of which they conſiſt, they are totally different from every other kind of mineral; and that, on the contrary, they greatly reſemble vegetable reſins in almoſt every reſpect. In ſhort, though they are not immediately procured from vegetables, there is the greateſt reaſon for believing that they were originally of the vegetable kingdom, and that they are no other than reſinous and oily parts of trees or plants, which by lying long in the earth, and there contracting an union with the mineral acids, have acquired the qualities that diſtinguiſh them from reſins.

Mineralogiſts know very well that we find, every where in the earth, many vegetable ſubſtances, that have lain very long buried under it, and frequently at a conſiderable depth. It is not uncommon to find, under ground, vaſt beds of foſſile trees, which ſeem to be the remains of immenſe foreſts; and bitumens, particularly amber, are often found among this ſubterraneous wood.

Theſe conſiderations, joined to proofs drawn from their analyſis, make this opinion more than probable: nor are we ſingular in maintaining it, as it is adopted by many able modern chemiſts.

The analyſis of amber, above deſcribed, may ſerve as a general ſpecimen of the decompoſition of other bitumens: with this ſingle difference, that amber is the only one among them which yields the volatile ſalt aforeſaid; and this determined us to examine it preferably to any other. As for the reſt, they all yield a phlegm, an acid liquor, and an oil; which is thin at firſt, but grows thicker and thicker as the diſtillation draws towards an end. It muſt be underſtood, however, that theſe acids and theſe oils may differ, according to the nature of the bitumens from which they are drawn; juſt as the phlegm, the acid, and the oil, reſulting from the decompoſition of reſins, differ in quantity and quality, according to the nature of the reſins from which they are procured.

The

The principal differences obferved between refins and bitumens are thefe: the latter are lefs foluble in fpirit of wine; have a peculiar fcent, which cannot be accurately defcribed, and of which the fenfe of fmelling only can judge; and their acid is ftronger and more fixed. This laft property is one of the motives which induce us to think, that befides the vegetable acid, originally combined with the refinous or oily matter now become a bitumen, a certain quantity of mineral acid hath, in a courfe of time, been fuperadded to conftitute this mixt. We fhall prefently fee that the fact is certainly fo, in the cafe of amber at leaft.

The Analyfis of Bees-wax.

Melt the wax you intend to analyfe, and mix with it as much fine fand as will make it into a ftiff pafte. Put this pafte in little bits into a retort, and diftil as ufual, with a graduated fire, beginning with a very gentle heat. An acid phlegm will come over, and be followed by a liquor which at firft will look like an oil, but will foon congeal in the receiver, and have the appearance of a butter or greafe. Continue the diftillation, increafing the fire by infenfible degrees, till nothing more will come off. Then feparate the butter from the acid phlegm in the receiver, mix it with frefh fand, and diftil it again juft as you did the wax before. Some acid phlegm will ftill come off, and an oil will afcend, which will not fix in the receiver, though it be ftill thick. Continue the diftillation, with a fire fo governed that the drops may fucceed each other at the diftance of fix or feven feconds of time. Do not increafe it, till you perceive the drops fall more flowly; and then increafe it no more than is neceffary to make the drops follow each other as above directed. When the diftillation is finifhed, you will find in the receiver the oil come wholly over, and a little acid phlegm. Separate the oil from this liquor; and, if you defire to have it more fluid, rediftil it a third time in the fame manner.

The Saccharine Juices of Plants analyfed: inftanced in Honey.

Put into a ftone cucurbit the honey you intend to diftil; fet it in a moderate fand-heat, and evaporate the greateft part of its humidity, till you perceive the phlegm to be acid. Then take out the matter remaining in the cucurbit, put it into a retort, leaving a full third thereof empty, and diftil in a reverberatory with degrees of fire. An acid amber-coloured liquor will come over. As the operation advances, this liquor will continually become deeper coloured and more acid, and at the fame time a little black oil will afcend. When the diftillation is over, you will find in the retort a pretty large charred mafs, which being burnt in the open air, and lixiviated, affords a fixed alkali.

Sugar, manna, and the faccharine juices of fruits and plants, are of the fame nature as honey, yield the fame principles, and in the fame proportions. All thefe fubftances muft be confidered as native foaps; becaufe they confift of an oil rendered mifcible with water, by means of a faline fubftance. They differ from the common artificial foaps in feveral refpects; but chiefly in this, that their faline part is an acid, whereas that of common foap is an alkali. The natural foaps are not for that reafon the lefs perfect: on the contrary, they diffolve in water without deftroying its tranfparency, and without giving it a milky colour; which proves, that acids are not lefs proper than alakalis, or rather that they are more proper additaments, for bringing oils into a faponaceous ftate.

Gummy Subftances analyfed: inftanced in Gum Arabic.

Distil gum arabic in a retort with degrees of fire. A limpid, fcentlefs, and taftelefs phlegm will firft come over; and then a ruffet coloured acid liquor, a little volatile alkali, and an oil, which will firft be thin and afterwards grow thick. In the retort will be left a good deal of a charred fubftance, which, being burnt and lixiviated, will give a fixed alkali.

Gums have at firft fight fome refemblance of refins; which hath occafioned many refinous matters to be called gums, though very improperly: for they are two diftinct forts of fubftances, of natures abfolutely different from each other. It hath been fhewn, that refins have an aromatic odour; that they are indiffoluble in water, and foluble in fpirit of wine; that they are only an effential oil grown thick. Gums, on the contrary, have no odour, are foluble in water, indiffoluble in fpirit of wine, and, by being analyfed as in the procefs, are converted almoft wholly into a phlegm and an acid. The fmall portion of oil contained in them is fo thoroughly united with their acid, that it diffolves perfectly in water, and the folution is clear and limpid. In this refpect gums refemble honey, and the other vegetable juices analogous to it. They are all fluid originally; that is, when they begin to ooze out of their trees. At that time they perfectly refemble mucilages, or rather they are actual mucilages, which grow thick and hard in time by the evaporation of a great part of their moifture: juft as refins are true oils, which, lofing their moft fluid parts by evaporation, at laft become folid. Infufions or flight decoctions of mucilaginous plants, when evaporated to drynefs, become actual gums.

Some trees abound both in oil and in mucilage: thefe two fubftances often mix and flow from the tree blended together. Thus they both grow dry and hard together in one mafs, which of courfe is at the fame time both gummy and refinous: and accordingly fuch mixts are named *gum refins*.

Of Operations on Fermented Vegetable Substances.

Of the Product of Spirituous Fermentation.

To make Wine of Vegetable Subftances that are fufceptible of Spirituous Fermentation.

Let a liquor fufceptible of, and prepared for, the fpirituous fermentation, be put into a cafk. Set this cafk in a temperately warm cellar, and cover the bung-hole with a bit of linen cloth only. In more or lefs time, according to the nature of the liquor to be fermented, and

and to the degree of heat in the air, the liquor will begin to ſwell, and be rarefied. There will ariſe an inteſtine motion, attended with a ſmall hiſſing and effervescence, throwing up bubbles to the ſurface, and diſcharging vapours; while the groſs, viſcous, and thick parts, being driven up by the fermenting motion, and rendered lighter by little bubbles of air adhering to them, will riſe to the top, and there form a kind of ſoft ſpungy cruſt, which will cover the liquor all over. The fermenting motion ſtill continuing, this cruſt will, from time to time, be lifted up and cracked by vapours making their eſcape through it; but thoſe fiſſures will preſently cloſe again, till, the fermentation gradually going off, and at laſt entirely ceaſing, the cruſt will fall in pieces to the bottom of the liquor, which will inſenſibly grow clear. Then ſtop the caſk cloſe with its bung, and ſet it in a cooler place.

Matters that are ſuſceptible of the ſpirituous fermentation are ſeldom ſo perfectly prepared for it by nature as they require to be. If we except the juices that flow naturally from certain trees, but oftener from inciſions made on purpoſe in them, all other ſubſtances require ſome previous preparation.

Boerhaave divides the ſubſtances that are fit for ſpirituous fermentation into five claſſes. In the firſt he places all the meally ſeeds, the legumens, and the kernels of almoſt all fruits. The ſecond claſs includes the juices of all fruits that do not tend to putrefaction. In the third claſs ſtand the juices of all the parts of plants which tend rather to acidity than to putrefaction; and conſequently thoſe which yield much volatile alkali are to be excluded. The fourth claſs comprehends the juices or ſaps that ſpontaneouſly diſtil from ſeveral trees and plants, or flow from them when wounded. He forms his fifth and laſt claſs of the ſaponaceous, ſaccharine, and concrete or thick juices of vegetables. Reſinous or purely gummy matters are excluded, as not being fermentable.

Theſe five claſſes may be reduced into two; one comprehending all the juices, and another all the meally parts of vegetables that are ſuſceptible of fermentation. The juices want nothing to fit them for fermentation, but to be expreſſed out of the ſubſtances containing them, and to be diluted with a ſufficient quantity of water. If they be very thick, the beſt way is to add ſo much water as ſhall render the mixed liquor juſt capable of bearing a new laid egg. With reſpect to farinaceous ſubſtances, as they are almoſt all either oily or mucilaginous, they require a little more management. The method of brewing malt liquors will furniſh us with examples of ſuch management See Brewing.

Beſides the preparations relating chiefly to malt liquors, there are many other things to be obſerved relating to ſpirituous fermentation in general, and to all matters ſuſceptible of that fermentation. For example, all grains and fruits deſigned for that fermentation muſt be perfectly ripe; for otherwiſe they will not ferment without difficulty, and will produce little or no inflammable ſpirit. Such matters as are too auſtere, too acrid, or aſtringent, are for the ſame reaſon unfit for ſpirituous fermentation; as well as thoſe which abound too much in oil.

In order to make the fermentation ſucceed perfectly, ſo as to produce the beſt wine that the fermented liquor is capable of affording, it is neceſſary to let it ſtand quiet without ſtirring it, leſt the cruſt that forms on its ſurface ſhould be broken to little fragments, and mix with the liquor. This cruſt is a kind of cover, which hinders the ſpirituous parts from exhaling as faſt as they are formed. The free acceſs of the air is another condition neceſſary to fermentation: and for this reaſon the veſſel that contains the fermenting liquor muſt not be cloſe ſtopped; the bung-hole is only to be covered with a linen cloth, to hinder dirt and inſects from falling into it. Nor muſt the bung-hole be too large, leſt too much of the ſpirituous parts ſhould eſcape and be loſt.

Laſtly, a juſt degree of warmth is one of the conditions moſt neceſſary for fermentation: for in very cold weather there is no fermentation at all; and too much heat precipitates it in ſuch a manner that the whole liquor becomes turbid, and many fermenting and fermented particles are diſſipated.

If, notwithſtanding the exacteſt obſervance of every particular requiſite to excite a ſucceſsful fermentation, the liquor cannot, without difficulty, be brought to effervesce, which ſcarce ever happens but to malt-liquor, it may be accelerated by mixing therewith ſome matter that is very ſuſceptible of fermentation, or actually fermenting. Such matters are called *ferments*. The cruſt that forms on the ſurface of fermenting liquors is a moſt efficacious ferment, and on that account very much uſed.

It ſometimes happens, that there is occaſion to check the fermentation excited in the liquor, before it ceaſes of itſelf. To effect this, ſuch means muſt be uſed as are directly oppoſite to thoſe mentioned above for promoting fermentation. The ſame end is obtained by mixing with the liquor a quantity of alkali, ſufficient to abſorb the acid contained therein: but this method is ſeldom made uſe of, becauſe it ſpoils the liquor; which, after being thus treated, is incapable of any ſpirituous fermentation, but on the contrary will certainly putrefy.

Spirituous fermentation may alſo be ſtopped by mixing with the liquor a great quantity of ſome mineral acid. But this likewiſe alters its nature; becauſe theſe acids, being fixed, always remain confounded therewith, and never ſeparate from it.

The beſt method yet found out for checking this fermentation, without injury to the fermenting liquor, is to impregnate it with the fumes of burning ſulphur. Theſe fumes are known to be acid; and it is that quality in them which ſuſpends the fermentation. But at the ſame time this acid is extremely volatile; ſo that it ſeparates ſpontaneouſly from the liquor, after ſome time, and leaves it in a condition to continue its fermentation.

For this reaſon, when a wine is deſired that ſhall be but half fermented, and ſhall partly retain the ſweet taſte it had in the ſtate of *muſt*, (the proper name for the unfermented juice of the grape), it is put into caſks in which ſulphur hath been previouſly burnt, and the vapours thereof confined by ſtopping the bung-hole. Theſe are called *matched wines*. If the ſame operation be performed on muſt, its fermentation will be abſolutely prevented: it will retain all its ſaccharine taſte, and is then called

called *ſtum*. As the ſulphureous acid evaporates ſpontaneouſly, in no long ſpace, it is neceſſary to fumigate matched wines or ſtums from time to time, when they are intended to be kept long without fermenting.

To draw an Ardent Spirit from Subſtances that have undergone the Spirituous Fermentation. — The Analyſis of Wine.

Fill a large copper cucurbit half full of wine. Fit on its head and refrigeratory. Lute on a receiver with wet bladder, and diſtill with a gentle fire; yet ſo that the drops which fall from the noſe of the alembic may ſucceed one another pretty quick, and form a ſort of ſmall continued ſtream. Go on thus till you perceive that the liquor which comes over ceaſes to be inflammable; and then deſiſt. You will find in the receiver a clear liquor, ſomewhat inclining to an amber-colour, of a pleaſant quick ſmell, and which being thrown into the fire inſtantly flames. The quantity thereof will be nearly a fourth part of the wine you put into the alembic; and this is what is called *brandy*; that is, the ardent ſpirit of wine loaded with much phlegm.

In order to rectify it, and reduce it to ſpirit of wine, put it into a long-necked matras, capable of holding double the quantity. Fit a head to the matras, and lute on a receiver: place your matras over a pot half full of water: ſet this pot over a moderate fire; and with this vapour-bath diſtil your ſpirit, which will riſe pure. Continue this degree of heat till nothing more will come over. You will find in the receiver a very clear colourleſs ſpirit of wine, of a quick but agreeable ſmell, which will catch fire at once by the bare contact of any flaming ſubſtance.

To dephlegmate Spirit of Wine by the Means of Fixed Alkalis.

Into a glaſs cucurbit pour the ſpirit of wine you intend to dephlegmate, and add to it about a third part of its weight of fixed alkali, newly calcined, perfectly dry, heated, and pulveriſed. Shake the veſſel, that the two matters may be mixed and blended together. The ſalt will gradually grow moiſt, and, if the ſpirit of wine be very aqueous, melt into a liquor, that will always lie at the bottom of the veſſel, without uniting with the ſpirit of wine which will ſwim at top.

When you perceive that the alkali attracts no new moiſture, and that no more of it melts, decant your ſpirit of wine from the liquor beneath it, and add to your ſpirit freſh ſalt thoroughly dried as before. This ſalt alſo will imbibe a little moiſture; but it will not grow liquid, becauſe the alkali, with which it was mixed before, hath left too little phlegm to melt this. Decant it from this ſalt as at firſt, and continue to mix and ſhake it in the ſame manner with freſh ſalt, till you obſerve that the ſalt remains as dry after as it was before mixing it with the ſpirit of wine. Then diſtil your ſpirit in a ſmall alembic with a gentle heat, and you will have it as much dephlegmated as it can be.

Spirit of Wine combined with different Subſtances.

To combine Spirit of Wine with the Vitriolic Acid. This Combination decompounded. Æther.

Into an Engliſh glaſs retort put two pounds of ſpirit of wine perfectly dephlegmated, and pour on it at once two pounds of highly concentrated oil of vitriol: ſhake the retort gently ſeveral times, in order to mix the two liquors. This will produce an ebullition, and conſiderable heat; vapours will aſcend, with a pretty loud hiſſing noiſe, which will diffuſe a very aromatic ſmell, and the mixture will be of a deeper or lighter red colour, according as the ſpirit of wine was more or leſs oily. Set the retort on a ſand-bath made nearly as hot as the liquor; lute on a tubulated ballon, and diſtil the mixture with a fire ſtrong enough to keep the liquor always boiling; a very aromatic ſpirit of wine will firſt come over into the ballon, after which the æther will riſe. When about five or ſix ounces of it are come off, you will ſee in the upper concavity of the retort a vaſt number of little points in a veined form, which will appear fixed, and which are nevertheleſs ſo many little drops of æther, rolling over one another, and trickling down into the receiver. Theſe little points continue to appear and ſucceed each other to the end of the operation. Keep up the ſame degree of fire, till upon opening the little hole in the ballon you perceive that the vapours, which inſtantly fill the receiver, have the ſuffocating ſmell of volatile ſpirit of ſulphur.

Then unlute the ballon, pour the liquor it contains into a cryſtal bottle, and ſtop it cloſe: there will be about eighteen ounces of it. Lute on your receiver again, and continue the diſtillation with a greater degree of fire. There will come over an aqueous, acid liquor, ſmelling ſtrong of a ſulphureous ſpirit, which is not inflammable. It will be accompanied with undulating vapours; which being condenſed will form an oil, moſt commonly yellow, one part of which will float on the ſurface of the liquor, and another will ſink to the bottom.

Towards the end of the diſtillation of this acid liquor, and of the yellow oil of which it is the vehicle, that part of the mixture, which is left in the retort and grown black, will begin to riſe in froth. Then ſuppreſs your fire at once, ſtop the diſtillation, and change your receiver once more. When the veſſels are grown pretty cool, finiſh your diſtillation with a lamp-heat kept up for twelve or fifteen days, which in all that time will raiſe but a very little ſulphureous ſpirit. Then break your retort, in which you will find a black, ſolid maſs, like a bitumen. It will have an acid taſte, ariſing from a remainder of the acid imperfectly combined with oil.

This artificial bitumen may be freed from its redundant acid, by waſhing it in ſeveral waters. Then put it into a glaſs retort, and diſtil it with a ſtrong reverberated fire. You will obtain a reddiſh oil that will ſwim on water, much like the oil obtained by diſtilling the natural bitumens.

bitumens. This oil alſo will be accompanied with an aqueous acid liquor. In the retort will be left a charred matter, which, being put into an ignited crucible in the fire, burns for ſome time, and, when well calcined, leaves a white earth.

The liquors that riſe firſt in this diſtillation, and which we directed to be kept by themſelves, are a mixture conſiſting, 1. of a highly dephlegmated ſpirit of wine, of a moſt fragrant ſmell; 2. of æther, which the ſpirit of wine wherewith it is united renders miſcible with water; 3. of a portion of oil, which commonly riſes with the æther towards the end of the operation; 4. and ſometimes of a little ſulphureous acid, if the receiver be not changed ſoon enough.

In order to ſeparate the æther from theſe other ſubſtances, put the whole into an Engliſh retort, with a little oil of tartar *per deliquium* to abſorb the ſulphureous acid, and diſtil very ſlowly in a ſand-bath heated by a lamp, till near half the liquor be come over. Then ceaſe diſtilling; put the liquor in the receiver into a phial with ſome water, and ſhake it; you will ſee it riſe with rapidity to the upper part of the phial, and float on the ſurface of the water: this is the æther.

Spirit of Wine combined with Spirit of Nitre. Sweet Spirit of Nitre.

Into an Engliſh retort of cryſtal glaſs put ſome highly rectified ſpirit of wine; and, by means of a glaſs funnel with a long pipe let fall into your ſpirit of wine a few drops of the ſmoking ſpirit of nitre. There will ariſe in the retort an effervеſcence attended with heat, red vapours, and a hiſſing noiſe like that of a live coal quenched in water. Shake the veſſel a little, that the liquors may mix thoroughly, and that the heat may be equally communicated to the whole. Then add more ſpirit of nitre, but in a very ſmall quantity, and with the ſame precautions as before. Continue thus adding ſpirit of nitre, by little and little at a time, till you have put into the retort a quantity equal to a third part of your ſpirit of wine. Let this mixture ſtand quiet, in a cool place, for ten or twelve hours; then ſet it to digeſt in a very gentle warmth for eight or ten days, having firſt luted on a receiver to the retort

During this time a ſmall quantity of liquor will come over into the receiver, which muſt be poured back into the retort. Then diſtill with a ſomewhat ſtronger degree of heat, but ſtill very gently, till nothing be left in the retort but a thick matter. In the receiver you will find a ſpirituous liquor, of a quick grateful ſmell, which will excite a very ſmart ſenſation on the tongue, but without any corroſive acrimony. This is the *ſweet ſpirit of nitre.*

Spirit of Wine combined with the Acid of Sea-ſalt. Dulcified Spirit of Salt.

Mix together, little by little, in a glaſs retort, two parts of ſpirit of wine with one part of ſpirit of ſalt. Set this mixtnre to digeſt for a month in a gentle heat, and diſtill it, till nothing remain in the retort but a thick matter.

The acid of ſea-ſalt is much leſs diſpoſed to unite with inflammable matters than the other two mineral acids; and therefore, though it be ever ſo highly concentrated when mixed with ſpirit of wine, it never produces effervеſcence comparable to that which is produced by the ſpirit of nitre. Neither the proportion nor ſtrength of the ſpirit of ſalt, requiſite to prepare the ſweet ſpirit of ſalt, are unanimouſly agreed upon by authors. Some direct equal parts of the two liquors; while others preſcribe from two to four or five parts of ſpirit of wine to one part of ſpirit of ſalt. Some uſe only common ſpirit of ſalt; others require the ſmoking ſpirit diſtilled by means of ſpirit of vitriol. Laſtly, ſome order the mixture to be diſtilled, after ſome days digeſtion; and others content themſelves with barely digeſting it. The whole depends on the degree of ſtrength which the ſweet ſpirit of ſalt is intended to have. This compoſition, as well as the ſweet ſpirit of nitre, is eſteemed in medicine to be very aperitive and diuretic.

When the mixture of ſpirit of ſalt and ſpirit of wine is diſtilled, there comes over but one liquor, which appears homogeneous. This is the *ſweet ſpirit of ſalt.* The nature of the marine acid is not changed in this combination: the acid is only weakened and rendered more mild: but in other reſpects it retains its characteriſtic properties.

Oils, or Oily matters, that are ſoluble in Spirit of Wine, ſeparated from Vegetables, and diſſolved by means of that Menſtruum. Tinctures; Elixirs; Varniſhes. Aromatic ſtrong waters.

Put into a matras the ſubſtances from which you intend to extract a tincture, having firſt pounded them. or pulveriſed them if they are capable of it. Pour upon them ſpirit of wine to the depth of three fingers breadth. Cover the matras with a piece of wet bladder, and tie it on with packthread. Make a little hole in this bit of bladder with a pin, leaving it in the hole to keep it ſtopped. Set the matras in a ſand-bath very gently heated. If the ſpirit of wine diſſolve any part of the body. it will accordingly acquire a deeper or lighter colour. Continue the digeſtion till you perceive that the ſpirit of wine gains no more colour. From time to time pull out the pin to give vent to the vapours, or rarefied air, which might otherwiſe burſt the matras. Decant your ſpirit of wine, and keep it in a bottle well corked. Pour on ſome freſh ſpirit in its ſtead: digeſt as before; and go on in this manner, pouring on and off freſh ſpirit of wine, till the laſt come off colourleſs.

Spirit of wine impregnated with ſuch parts of any vegetable ſubſtance as it is capable of diſſolving, is commonly called a *tincture*. Several tinctures mixed together, or a tincture drawn from ſundry vegetable ſubſtances at the ſame time, and in the ſame veſſel, take the name of an *elixir*. Tinctures of elixirs impregnated with reſinous matters only, are true *varniſhes*. All theſe preparations are made in the ſame manner; to wit, as directed in our proceſs. We ſhall only add here, that if the ſubſtances from which a tincture or elixir is to be made contain too much moiſture, it is proper to free them from it by gentle deſiccation; eſpecially if you deſign that the tincture ſhould be well impregnated with the oily and reſinous

resinous parts: for their excess of moisture uniting with the spirit of wine would weaken it, and render it unable to act on those matters, which it cannot dissolve when it is aqueous.

If your tinctures or elixirs be not so strong or so saturated as you desire, you may by distillation abstract part of the spirit of wine which they contain, and by that means give them such a degree of thickness as you judge proper. But the spirit of wine thus drawn off constantly carries along with it a good deal of the aromatic principle. It is a truly *aromatic strong water*. This spirit of wine also carries up with it a portion of thin oil, which is so much the more considerable as the degree of heat employed is greater: and this is the reason why it becomes of a milky colour when mixed with water.

If you intend to make an aromatic strong water only, you need not previously extract a tincture from the vegetable substance with which you mean to prepare your water: you need only put it in a cucurbit, pour spirit of wine upon it, and distil with a gentle heat. By this means you will obtain a spirit of wine impregnated with all the odour of the plant.

Of TARTAR.

Tartar analysed by distillation. The Spirit, Oil, and Alkaline Salt of Tartar.

INTO a stone retort, or a glass one coated with lute, put some white tartar broken into small bits; observing that one half, or at least a full third, of the vessel be left empty. Set your retort in a reverberating furnace. Fit on a large ballon, having a small hole drilled in it: lute it exactly with fat lute, and secure the joint with a linen cloth smeared with lute made of quick-lime and the white of an egg. Apply at first an exceeding gentle heat, which will raise a limpid, sourish, pungent water, having but little smell, and a bitterish taste.

When this first phlegm ceases to come off, increase your fire a little, and make the degree of heat nearly equal to that of boiling water. A thin, limped oil will rise, accompanied with white vapours, and with a prodigious quantity of air, which will issue out with such impetuosity, that if you do not open the little hole in the receiver time enough to give it vent, it will burst the vessels with explosion. An acid liquor will rise at the same time. Continue the distillation, increasing the heat by insensible degrees, and frequently unstopping the little hole of the receiver, till the elastic vapours cease to issue, and the oil to distil.

Then raise your fire more boldly. The acid spirit will continue to rise, and will be accompanied with a black, fetid, empyreumatic, ponderous, and very thick oil. Urge the fire to the utmost extremity, so that the retort may be of a perfect red heat. This violent fire will raise a little volatile alkali, besides a portion of oil as thick as pitch. When the distillation is finished, you will find in the retort a black, saline, charred matter, which grows hot when wetted, attracts the moisture of the air, runs *per deliquium*, and hath all the properties of a fixed alkali.

The mass, being exposed to a naked fire in the open air, burns, consumes, and is reduced to a white ash, which is a fiery, caustic, fixed alkali.

The lees of wine resemble tartar, in as much as they contain, and yield when analised, the same principles; but they differ from it in this, that they contain, moreover, a greater quantity of earth, of phlegm, and a little ardent spirit, which are only mixed, but not united, with its tartarous acid.

The Depuration of Tartar. Cream and Crystals of Tartar.

REDUCE to a fine powder the tartar you intend to purify, and boil it in twenty five or thirty times as much water. Filter the boiling liquor through a flannel bag, and then gently evaporate some part of it: there will soon form on its surface a saline crust, which is the *cream of tartar*. Let your liquor cool, and there will adhere to the sides of the vessel a great quantity of a crystallised saline matter, which is *crystal of tartar*.

Crystal of Tartar combined with several substances.

Crystal of Tartar combined with Absorbent Earths. Soluble Tartars.

BOIL an absorbent earth, such as chalk, in a pan with water; and, when you perceive the earth thoroughly divided and equally distributed through the water, throw into the pan, from time to time, some pulverised crystal of tartar, which will excite a considerable effervescence. Continue these projections, till you observe no effervescence excited thereby. All the absorbent earth, which obscured the transparency of the water, and gave it an opaque white colour, will gradually disappear as the crystal of tartar combines with it; and when the combination is perfected, the liquor will be clear and limpid. Then filter it, and there will be left on the filter but a very small quantity of earth. Evaporate all the filtered liquor with a gentle heat; and then set it in a cool place to shoot. Crystals will form therein, having the figure of flat quadrangular prisms, with almost always one, sometimes two, of the angles of the prism shaved down, as it were; and then the surfaces at each end are oblique answering to those depressed angles. These crystals are a neutral salt which readily dissolves in water; a true *soluble tartar*.

Crystal of Tartar combined with fixed Alkalis. The Vegetable Salt. Saignette's Salt. The decomposition of Soluble Tartars.

IN eight parts of water dissolve one part of a very pure alkaline salt, perfectly freed from the phlogiston by calcination. Heat this lixivium in a stone pan set on a sand bath, and from time to time throw into it a little powdered cream or crystal of tartar. Each projection will excite a great effervescence, attended with many bubbles, which will rise to a considerable height one over the other. Stir the liquor when the effervescence ceases, and you will see it begin again.

When no effervescence appears upon ftirring the liquor, add a little more cream of tartar, and the fame phenomena will be renewed. Go on thus till you have obtained the point of perfect faturation.

Then filter your liquor. If the alkali you made ufe of was the falt of Soda, evaporate your liquor quickly to a pellicle, and there will fhoot in it cryftals of nine fides refembling a coffin; the bottom part thereof being concave, and ftreaked with a great many parallel lines; and this is *Saignette's falt*. If you have employed any other alkali but foda, or the bafis of fea-falt, evaporate your liquor flowly to the confiftence of a fyrup: let it ftand quiet, and there will form in it cryftals having the figure of flatted parallelopipeds; and this is the *vegetable falt*, or *tartarifed tartar*.

All foluble tartars are eafily decompounded, by means of a certain degree of heat. They yield in diftillation the fame principles as tartar; and the alkali that remains, when they are perfectly calcined, confifts of that which the tartar naturally affords, and of the alkaline matter with which it was converted into a neutral falt.

Cryftal of Tartar combined with Iron. Chalybeated Tartar. Tincture of Steel with Tartar. Soluble Chalybeated Tartar.

Mix four ounces of iron in filings with one pound of white tartar finely pulverifed, Boil the mixture in about twelve times as much water as you took of tartar. When the faline part of the tartar is diffolved, filter the liquor boiling-hot through a flannel bag, and then fet it in a cool place. In a very little time cryftals of a ruffet colour will fhoot therein. Decant the liquor from thefe cryftals; evaporate it to a pellicle, and fet it again to cryftallife. Go on in this manner till it will fhoot no more. Collect all the falt you have thus obtained, and keep it under the name of *chalybeated tartar*.

To make the tincture of fteel with tartar, mix together fix ounces of clean iron filings, and one pound of white tartar in powder. Put this mixture into a large iron kettle, and pour thereon as much rain-water as will moiften it. Make a pafte of this matter, and leave it thus in a mafs for twenty-four hours. Then pour on it twelve pounds of rain-water, and boil the whole for twelve hours at leaft, ftirring the mixture frequently, and adding from time to time fome hot water, to fupply the place of what evaporates. When you have thus boiled the liquor, let it ftand quiet for fome time, and then pour it off from the fediment at bottom. Filter, and evaporate to the confiftence of a fyrup; and you have the *tincture of Mars with tartar*. The difpenfatories generally order an ounce of rectified fpirit of wine to be poured on this tincture, in order to preferve it, and to keep it from growing mouldy, as it is very apt to do.

Soluble chalybeated tartar is prepared by mixing four ounces of tartarifed tartar with one pound of the tincture of Mars with tartar, and evaporating them together in an iron veffel to drynefs; after which it is kept in a well ftopped phial to prevent its growing moift in the air.

Cryftal of Tartar combined with the reguline part of Antimony. Stibiated or Emetic tartar.

Pulverise and mix together equal parts of the glafs and of the liver of antimony. Put this mixture, with the fame quantity of pulverifed cream of tartar, into a veffel capable of containing as much water as will diffolve the cream of tartar. Boil the whole for twelve hours, from time to time adding warm water, to replace what is diffipated by evaporation. Having thus boiled your liquor, filter it while boiling hot; evaporate to drynefs; and you will have a faline matter, which is *emetic tartar*.

Of the Product of Acetous Fermentation.

Subftances fufceptible of the Acetous Fermentation turned into Vinegar.

The wine, the cyder, or the malt-liquor, you intend to convert into vinegar, being firft thoroughly mixed with its lees, and with the tartar it may have depofited, put your liquor into a fat ufed before either for making or for holding vinegar. This veffel muft not be quite full, and the external air muft have accefs to the liquor contained in it. Set it where the air may have a degree of warmth anfwering nearly to the twentieth degree above 0 in Mr de Rèaumur's thermometer. Stir the liquor from time to time. There will arife in it a new fermentative motion, accompanied with heat: its vinous odour will gradually change, and turn to a four fmell, which will become ftronger and ftronger till the fermentation be finifhed and ceafe of itfelf. Then ftop your veffel clofe; the liquor it contains will be found converted into vinegar.

All fubftances that have undergone the fpirituous fermentation are capable of being changed into an acid by paffing through this fecond fermentation, or this fecond ftage of fermentation. Spirituous liquors, fuch as wine, cyder, beer, being expofed to a hot air, grow four in a very fhort time. Nay, thefe liquors, though kept with all poffible care, in very clofe veffels, and in a cool place, degenerate at laft, change their natures, and infenfibly turn four. Thus the product of fpirituous fermentation naturally and fpontaneoufly degenerates to an acid.

For this reafon it is of great importance, in making wine, or any other vinous liquor, to ftop the fermentation entirely, if you defire the wine fhould contain as much fpirit as poffible. It is even more advantageous to check the fermentation a little before it come to the height than afterwards: becaufe the fermentation, tho' flackened and in appearance totally ceafed, ftill continues in the veffels; but in a manner fo much the lefs perceptible as it proceeds more flowly. Thus thofe liquors, in which the fermentation is not quite finifhed, but checked, continue for fome time to gain more fpirit; whereas, on the contrary, they degenerate and gradually turn four, if you let the fpirituous fermentation go on till it be entirely finifhed.

The production of the fecond fermentation, which we are now to confider, is an acid of fo much the greater ftrength,

ſtrength, the ſtronger and more generous the ſpirituous liquor in which it is excited originally was. The ſtrength of this acid, commonly called *vinegar*, depends likewiſe in a great meaſure on the methods uſed in fermenting the vinous liquor, in order to convert it into vinegar: for if it be fermented in broad, flat veſſels, and left to grow ſour of itſelf, the ſpirituous parts will be diſſipated, and the liquor be ſour indeed, but vapid and effete.

The vinegar-makers, to increaſe the ſtrength of their vinegar, uſe certain methods of which they make a myſtery, keeping them very ſecret. However, Mr. Boerhaave give us, from ſome authors, the following deſcription of a proceſs for making vinegar:

" Take two large oaken vats or hogſheads, and in each of theſe place a wooden grate or hurdle, at the diſtance of a foot from the bottom. Set the veſſel upright, and on the grates place a moderately cloſe layer of green twigs, or freſh cuttings of the vine. Then fill up the veſſel with the foot-ſtalks of grapes, commonly called the *rape*, to within a foot of the top of the veſſel, which muſt be left quite open.

" Having thus prepared the two veſſels, pour into them the wine to be converted into vinegar, ſo as to fill one of them quite up, and the other but half full. Leave them thus for twenty-four hours, and then fill up the half-filled veſſel with liquor from that which is quite full, and which will now in its turn be left only half full. Four and twenty hours afterwards repeat the ſame operation, and go on thus, keeping the veſſels alternately full and half full during every twenty-four hours, till the vinegar be made. On the ſecond or third day there will ariſe, in the half-filled veſſel, a fermentative motion, accompanied with a ſenſible heat, which will gradually increaſe from day to day. On the contrary, the fermenting motion is almoſt imperceptible in the full veſſel; and as the two veſſels are alternately full and half full, the fermentation is by that means, in ſome meaſure, interrupted, and is only renewed every other day, in each veſſel.

" When this motion appears to be entirely ceaſed, even in the half-filled veſſel, it is a ſign that the fermentation is finiſhed; and therefore the vinegar is then to be put into common caſks cloſe ſtopped, and kept in a cool place.

" A greater or leſs degree of warmth accelerates or checks this, as well as the ſpirituous fermentation. In France it is finiſhed in about fifteen days, during the ſummer; but if the heat of the air be very great, and exceed the twenty-fifth degree of Mr de Réaumur's thermometer, the half-filled veſſel muſt be filled up every twelve hours; becauſe if the fermentation be not ſo checked in that time, it will become ſo violent, and the liquor will be ſo heated, that many of the ſpirituous parts, on which the ſtrength of the vinegar depends, will be diſſipated; ſo that nothing will remain, after the fermentation, but a vapid waſh, ſour indeed, but effete. The better to prevent the diſſipation of the ſpirituous parts, it is a proper and uſual precaution to cloſe the mouth of the half-filled veſſel, in which the liquor ferments, with a cover made alſo of oak wood. As to the full veſſel, it is always left open, that the air may act freely on the liquor it contains: for it is not liable to the ſame inconveniences, becauſe it ferments but very ſlowly."

The vine-cuttings and grape-ſtalks, which the vinegar-makers put into their veſſels, ſerve to increaſe the ſtrength of the liquor. Theſe matters contain a very manifeſt and perceptible acid. They alſo ſerve as a ferment; that is, they diſpoſe the wine to become eager more expeditiouſly and more vigorouſly. They are the better and the more efficacious for having been once uſed, becauſe they are thereby thoroughly drenched with the fermented acid: and therefore the vinegar-makers lay them by for preparing other vinegar, after waſhing them nimbly in running water, in order to free them from a viſcid oily matter which ſettles on them during the fermentation. This matter muſt by all means be removed; becauſe it is diſpoſed to grow mouldy and rot; ſo that it cannot but be prejudicial to any liquor in which you put it.

As the acetous fermentation differs from the ſpirituous in its production, ſo it doth in many circumſtances attending it. 1. Motion and agitation are not prejudicial to the acetous fermentation, as they are to the ſpirituous; on the contrary, moderate ſtirring, provided it be not continual, is of ſervice to it. 2. This fermentation is accompanied with remarkable heat; whereas the warmth of the ſpirituous fermentation is ſcarce ſenſible. 3. We do not believe there ever was an inſtance of the vapour that riſes from a liquor in acetous fermentation proving noxious, and producing either diſorders or ſudden death, as the vapour of fermenting wine doth. 4. Vinegar depoſites a viſcid oily matter, as hath juſt been obſerved, very different from the lees and tartar of wine. Vinegar never depoſites any tartar; even though new wine, that hath not yet depoſited its tartar, ſhould be uſed in making it.

To concentrate Vinegar by Froſt.

Expose to the air, in froſty weather, the vinegar you deſire to concentrate. Icicles will form in it; but the whole liquor will not freeze. Take out thoſe icicles: and if you deſire a further concentration of your vinegar by this method, the liquor which did not freeze the firſt time muſt be expoſed to a ſtronger froſt. More icicles will form therein, which muſt likewiſe be ſeparated, and kept by themſelves. The liquor which doth not freeze this ſecond time will be a very ſtrong concentrated vinegar.

Vinegar analyſed by Diſtillation.

Into a glaſs or ſtone cucurbit put the vinegar to be diſtilled; fit to it a glaſs head; place your alembic in the ſand-bath of a diſtilling furnace, and lute on a receiver. Apply a very gentle heat at firſt. A clear, limpid, light liquor will riſe, and fall in diſtinct drops, like water, from the noſe of the alembic.

Continue diſtilling this firſt liquor, till the vinegar contained in the cucurbit be diminiſhed about a fourth part. Then ſhift your receiver, and increaſe the fire a little. A clear liquor will ſtill come over, but heavier and more acid

acid than the former. Distil in this manner till you have drawn off into your second receiver two thirds of the liquor that was left in the cucurbit.

A thick matter will now remain at the bottom of the still: put it into a retort; lute on a receiver; set your retort in a reverberating furnace, and distil with degrees of fire. There will come over a limpid liquor, very acid and sharp, yet ponderous, and requiring a great degree of fire to raise it; on which account it makes the receiver very hot. It hath a strong empyreumatic smell. When the distillation begins to slacken, increase your fire. There will rise an oil of a fetid, quick smell. At last when nothing more will rise with the strongest fire, break the retort, and in it you will find a black, charred matter: burn it, and from the ashes lixiviated with water you will obtain a fixed alkali.

The Acid of Vinegar combined with different Substances.

The Acid of Vinegar combined with Alkaline Substances. Foliated Salt of Tartar, or regenerated Tartar. Decomposition of that Salt.

INTO a glass cucurbit put some very pure and well dried salt of tartar; and pour on it some good distilled vinegar, by little and little at a time. An effervescence will arise. Pour on more vinegar, till you attain the point of saturation. Then fit a head to the cucurbit; set it in a sand bath: and, having luted on a receiver, distil with a gentle heat, and very slowly, till nothing remain but a dry matter. On this residuum drop a little of the same vinegar; and if any effervescence appears, add more vinegar till you attain the point of saturation, and distil again as before. If you observe no effervescence, the operation was rightly performed.

It is not easy to hit the exact point of saturation in preparing this neutral salt; because the oily parts, with which the acid of vinegar is loaded, hinder it from acting so briskly and readily as it would do, if it were as pure as the mineral acids: and for this reason it often happens, that, when we have nearly attained the point of saturation, the addition of an acid makes no sensible effervescence, though the alkali be not yet entirely saturated; which deceives the operator, and makes him conclude erroneously that he hath attained the true point of saturation.

But he easily perceives his mistake, when, after having separated from this saline compound all its superfluous moisture by distillation, he drops fresh vinegar upon it: for then the salts being more concentrated and consequently more active, produce an effervescence, which would not have been sensible if this last portion of acid, instead of coming into immediate contact with the dried alkali, could not have mixed therewith till diffused through, and in a manner suffocated by that phlegm from which the acid of the vinegar before neutralised was gradually separated by its combining with the alkali; that phlegm keeping in solution both the neutral salt already formed, and the alkali not yet saturated. And for this reason it is necessary to try, after the first desiccation of this salt, which is called *regenerated tartar*, whether or no the just point of saturation hath been attained.

From what hath been said, concerning the desiccation of this neutral salt, it is plain, that the use of it is only to free the salt from the great quantity of superfluous moisture wherein it is dissolved: which proves, that the acid of vinegar, like all other acids dissolved in much water, is separated from most of this redundant phlegm by being combined with a fixed alkali. And hence we must conclude, that the acid of vinegar, contained in regenerated tartar desiccated, is vastly stronger and more concentrated than it was before.

Though the acid of vinegar is freed, by combining with a fixed alkali, from a great quantity of superfluous phlegm, yet the oily parts with which it is entangled still cleave to it: these parts are not separated from it by its conversion into a neutral salt, but, without quitting it, combine also with the fixed alkali; and this gives regenerated tartar a saponaceous quality, and several other peculiar properties.

Regenerated tartar, when dried, is of a brown colour. It is semi-volatile; melts with a very gentle heat, and then resembles an unctuous liquor; which indicates its containing an oil: when cast upon live coals, it flames; and, when distilled with a strong heat, yields an actual oil; all which evidently proves the existence of that oil.

This salt is soluble in spirit of wine; a quality which it probably owes also to its oil. It requires about six parts of spirit of wine to dissolve it; and the dissolution succeeds very well in a matras, with the help of a gentle warmth. If the spirit of wine be abstracted from this solution, by distilling with a small fire, it remains at the bottom of the cucurbit, in the form of a dry substance composed of leaves lying one upon another; which hath procured it the name of *terra foliata tartari*, or *foliated salt of tartar*.

It is not absolutely necessary that regenerated tartar be dissolved in spirit of wine to make the foliated salt: for it may be procured in this form only by evaporating the water in which it is dissolved. But the operation succeeds better with spirit of wine; probably because the success thereof depends on using an exceeding gentle warmth: now spirit of wine evaporates with much less heat than water.

Regenerated tartar may also be crystallised. If you desire to have it in this form, combine the acid with the alkali to the point of saturation; evaporate the liquor slowly to the consistence of a syrup, and set it in a cool place; where it will shoot into clusters of crystals lying one upon another like feathers.

Vinegar perfectly dissolves absorbent matters also, and particularly those of the animal kingdom; such as corals, crabs eyes, pearls, *&c.* In order to a dissolution of such matters, you must pulverise them, put them into a matras, and pour on them spirit of vinegar to the depth of four fingers breadth: an effervescence will arise: when that is over, set the mixture to digest two or three days in a sand-bath; then decant the liquor, filter it, and evaporate it to dryness with a very gentle heat. The matter which remains is called *salt of coral*, *of pearls*,

of

of crabs-eyes, &c. according to the ſubſtances diſſolved. If, inſtead of evaporating the liquor, a fixed alkali be mixed therewith, the abſorbent matter, that was diſſolved by the acid, will precipitate in the form of a white powder, which is called the *magiſtery of coral*, *of pearls*, &c.

The Acid of Vinegar combined with copper. Verdegris. Cryſtals of Copper. This Combination decompounded. Spirit of Verdegris.

INTO a large matras put verdegris in powder. Pour on it diſtilled vinegar to the depth of four fingers breadth. Set the matras in a moderate ſand-heat, and leave the whole in digeſtion, ſhaking it from time to time. The vinegar will acquire a very deep blue-green colour. When the liquor is ſufficiently coloured, pour it off by inclination. Put ſome freſh vinegar into the matras; digeſt as before; and decant the liquor again when it is ſufficiently coloured. Proceed in this manner till the vinegar will extract no more colour. There will remain in the matras a conſiderable quantity of undiſſolved matter. The vinegar thus impregnated with verdegris is called *tincture of copper*.

Mix theſe ſeveral tinctures, and evaporate them with a gentle heat to a pellicle. Then ſet the liquor in a cool place: in the ſpace of a few days a great many cryſtals of a moſt beautiful green colour will ſhoot therein, and ſtick to the ſides of the veſſel. Pour off the liquor from the cryſtals; evaporate it again to a pellicle, and ſet it by to cryſtalliſe. Continue theſe evaporations and cryſtalliſations, till no more cryſtals will ſhoot in the liquor. Theſe are called *cryſtals of copper*, and are uſed in painting. To this combination of the acid of vinegar with copper the painters and dealers have given them the title of *diſtilled verdegris*.

Verdegris is prepared at Montpellier. To make it they take very clean plates of copper, which they lay, one over another, with huſks of grapes between, and after a certain time take them out. Their ſurfaces are then covered all over with a very beautiful green cruſt, which is *verdegris*. This verdegris is nothing but copper corroded by the acid of tartar, analogous to the acid of vinegar, which abounds in the wines of Languedoc, and eſpecially in the rape, huſks, and ſtones of grapes that have a very auſtere taſte. Verdegris is a ſort of ruſt of copper, or copper corroded and opened by the acid of wine, but not yet converted entirely into a neutral ſalt: for it is not ſoluble in water, nor does it cryſtalliſe. This ariſes from its not being united with a ſufficient quantity of acid. The deſign of the operation here deſcribed is to furniſh the verdegris with the quantity of acid requiſite to make it a true metallic ſalt; for which purpoſe diſtilled vinegar is very fit.

Cryſtals of copper may be obtained, without employing verdegris, by making uſe of copper itſelf diſſolved by the acid of vinegar, according to the method practiſed with reſpect to lead as ſhall be ſhewn hereafter. But verdegris is generally uſed, becauſe it diſſolves ſooneſt; it being a copper already half diſſolved by an acid correſpondent to that of vinegar.

Cryſtals of copper are decompounded by the action of fire alone, without any additament; becauſe the acid of vinegar adheres but looſely to copper. In order to decompound this ſalt, and extract its acid, it muſt be put into a retort, and diſtilled in a reverberatory furnace with degrees of fire. An inſipid phlegm riſes firſt, which is the water retained by the ſalt in cryſtalliſing. This phlegm is ſucceeded by an acid liquor, which riſes in the form of white vapours that fill the receiver. Towards the end of the diſtillation the fire muſt be violently urged, in order to raiſe the ſtrongeſt and moſt fixed acid. At laſt there remains in the retort a black matter, which is nothing but copper, that may be reduced by melting it in a crucible with one part of ſaltpetre and two parts of tartar. A ſimilar acid, but more oily, and in a much ſmaller quantity, may be obtained from verdegris by diſtillation.

The acid, which in this diſtillation comes over after the firſt phlegm, is an exceeding ſtrong and concentrated vinegar. It is known by the title of *ſpirit of verdegris*.

The Acid of Vinegar combined with Lead. Ceruſe. Salt or Sugar of Lead. This Combination decompounded.

INTO the glaſs head of a cucurbit put thin plates of lead, and ſecure them ſo that they may not fall out when the head is put upon the cucurbit. Fit on this head to a wide-mouthed cucurbit containing ſome vinegar. Set it in a ſand-bath; lute on a receiver, and diſtil with a gentle heat for ten or twelve hours. Then take off the head: in it you will find the leaden plates covered, and, in a manner, cruſted over with a white matter. This being bruſhed off with a hare's foot is what we call *ceruſe*. The leaden plates thus cleanſed may be employed again for the ſame purpoſe, till they be wholly converted into ceruſe by repeated diſtillations. During the operation there will come over into the receiver a liquor ſomewhat turbid and whitiſh. This is a diſtilled vinegar in which ſome lead is diſſolved.

Reduce a quantity of ceruſe into powder; put it into a matras; pour on it twelve or fifteen times as much diſtilled vinegar; ſet the matras in a ſand-bath; leave the matter in digeſtion for a day, ſhaking it from time to time: then decant your liquor, and keep it apart. Pour freſh vinegar on what is left in the matras, and digeſt as before. Proceed thus till you have diſſolved one half, or two thirds, of the ceruſe.

Evaporate to a pellicle the liquors you poured off from the ceruſe, and ſet them in a cool place. Greyiſh cryſtals will ſhoot therein. Decant the liquor from the cryſtals; evaporate it again to a pellicle, and ſet it by to cryſtalliſe. Proceed thus evaporating and cryſtalliſing, as long as any cryſtals will ſhoot. Diſſolve your cryſtals in diſtilled vinegar, and evaporate the ſolution, which will then ſhoot into whiter and purer cryſtals. This is the *ſalt*, or *ſugar of lead*.

Lead is eaſily diſſolved by the acid of vinegar. If it be barely expoſed to the vapour of that acid, its ſurface is corroded, and converted into a kind of calx or white ruſt, much uſed in painting, and known by the name of *ceruſe*, or *white lead*. But this preparation of lead is not combined with a ſufficient quantity of acid to convert it

it into a ſalt: it is no more than lead divided and opened by the acid of vinegar; a matter which is to lead what verdegris is to copper. And therefore if you deſire to combine ceruſe with the quantity of acid neceſſary to convert it into a true neutral ſalt, you muſt treat it in the ſame manner as we did verdegris in order to procure cryſtals of copper; that is, you muſt diſſolve it in diſtilled vinegar, as the proceſs directs.

The ſalt of lead is not very white when it firſt ſhoots; and for this reaſon it is diſſolved again in diſtilled vinegar, and cryſtalliſed a ſecond time. If ſalt of lead be repeatedly diſſolved in diſtilled vinegar, and the liquor evaporated, it will grew thick; but ſtill cannot be deſiccated without great difficulty. If the ſame operation be oftener repeated, this quality will be thereby more and more increaſed; till at laſt it will remain on the fire like an oil or melted wax: it coagulates as it cools, and then looks, at firſt ſight, like a metallic maſs, ſomewhat reſembling ſilver. This matter runs with a very gentle heat, almoſt as eaſily as wax.

The ſalt of lead hath a ſaccharine taſte, which hath procured it the name alſo of ſugar of lead. For this reaſon, when wine begins to turn ſour, the ſure way to cure it of that diſagreeable taſte, is to ſubſtitute a ſweet one which is not diſagreeable to the taſte, by mixing therewith ceruſe, litharge, or ſome ſuch preparation of lead; for the acid of the wine diſſolves the lead, and therewith forms a ſugar of lead, which remains mixed with the wine, and hath a taſte which, joined with that of the wine, is not unpleaſant. But, as lead is one of the moſt dangerous poiſons we know, this method ought never to be practiſed; and whoever uſes ſuch a pernicious drug deſerves to be moſt ſeverely puniſhed. Yet ſome thing very like this happens every day, and muſt needs have very bad conſequences; while there is nobody to blame, and thoſe to whom the thing may prove fatal can have no miſtruſt of it.

Salt of lead may be decompounded by diſtillation without additament. In order to perform this, you muſt put the ſalt of lead into a glaſs or ſtone retort, leaving a full third thereof empty, and diſtil in a reverberating furnace with degrees of fire. A ſpirit riſes, which fills the receiver with clouds. When nothing more will come over with a fire that makes the retort red-hot, let the veſſels cool, and then unlute them. You will find in the receiver an auſtere liquor, which is inflammable; or, at leaſt, an inflammable ſpirit may be obtained from it, if about one half thereof be drawn off by diſtillation in a glaſs alembic. The retort in which the ſalt of lead was decompounded contains, at the end of the operation, a blackiſh matter: this is lead, which will reſume its metallic form on being melted in a crucible; becauſe the acid by which it was diſſolved, and from which it hath been ſeparated, being of a very oily nature, hath left in it a ſufficient quantity of phlogiſton.

What is moſt remarkable in this decompoſition of ſalt of lead, is the inflammable ſpirit which it yields, though the vinegar which entered into the compoſition of the ſalt ſeemed to contain none at all.

Of the Putrid Fermentation of Vegetable Subſtances.

The Putrefaction of Vegetables.

Fill a hogſhead with green plants, and tread them down a little; or, if the vegetables be dry and hard ſubſtances, divide them into minute parts, and ſteep them a little in water to moiſten them: then leave them, or the green plants, in the veſſel, uncovered and expoſed to the open air. By degrees a heat will ariſe in the center of the veſſel, which will continue increaſing daily, at laſt grow very ſtrong, and be communicated to the whole maſs. As long as the heat is moderate, the plants will retain their natural ſmell and taſte. As the heat increaſes, both theſe will gradually alter, and at laſt become very diſagreeable, much like thoſe of putrid animal ſubſtances. The plants will then be tender as if they had been boiled; or even be reduced to a kind of pap, more or leſs liquid according to the quantity of moiſture they contained before.

Almoſt all vegetable matters are ſuſceptible of putrefaction; but ſome of them rot ſooner, and others more ſlowly. As putrefaction is only a ſpecies of fermentation, the effect whereof is to change entirely the ſtate of the acid, by combining it with a portion of the earth and oil of the mixt, which are ſo attenuated that from this union there reſults a new ſaline ſubſtance in which no acid is diſcernible; which on the contrary hath the properties of an alkali, but rendered volatile; it is plain, that, the nearer the acid of a plant ſet to putrefy is to this ſtate, the ſooner will the putrefaction of that plant be completed. Accordingly all plants that contain a volatile alkali ready formed, or from which it can be obtained by diſtillation, are the moſt diſpoſed to putrefaction.

Thoſe plants, in which the acid is very manifeſt and ſenſible, are leſs apt to putrefy; becauſe all their acid muſt undergo the change above ſpecified. But vegetable matters, whoſe acid is entangled and clogged by ſeveral of their other principles, muſt be ſtill longer elaborated before they can be reduced to the condition into which complete putrefaction brings all vegetables. The earthy and oily parts, in which the acids of theſe ſubſtances are ſheathed, muſt be attenuated and divided by a previous fermentation, which, of thoſe parts ſubtiliſed and united with the acid, forms an ardent ſpirit, wherein the acid is more perceptible than in the almoſt inſipid or ſaccharine juices out of which it is produced. The acid contained in the ardent ſpirit muſt be ſtill further diſengaged, before it can enter into the combination of a volatile alkali: conſequently the ardent ſpirit muſt undergo a ſort of decompoſition; its acid muſt be rendered more ſenſible, and be brought to the ſame condition as the acid of plants in which it manifeſts all its properties.

Hence it appears that the ſpirituous and acetous fermentations are only preparatives which nature makes uſe of for bringing certain vegetable matters to putrefaction. Theſe fermentations therefore muſt be conſidered as ad-

vances

vances towards that putrefaction in which they terminate, or rather as the first stages of putrefaction itself.

Putrefied Vegetable Substances analysed.

Put the putrefied plants you mean to analyse into a glass cucurbit, and set it in a sand-bath. Fit to it a head; lute on a receiver; distil with a gentle fire, and a limpid fetid liquor will come over. Continue the distillation till the matter contained in the retort be almost dry.

Then unlute your vessels, and keep the liquor you find in the receiver by itself. Put the matter remaining in the cucurbit into a retort, and distil with a graduated heat There will rise white vapours; a pretty considerable quantity of liquor nearly like that of the former distillation; a volatile salt in a concrete form; and a black oil, which towards the end will be very thick. In the retort there will remain a black charred matter, which being burnt in the open air will fall into ashes, from which no fixed alkali can be extracted.

By means of a funnel separate your oil from the aqueous liquor. Distil this liquor with a gentle heat. You will by this means obtain a volatile salt like that of animals; of which you may also get some, by the same means, from the liquor which came over in the first distillation.

This analysis shews the changes which putrefaction produces in vegetable matters. Scarce any of their principles are now to be discerned. They now yield no aromatic liquor; no essential oil; no acid; and consequently no essential salt, ardent spirit, or fixed alkali: in a word, whatever their natures were before putrefaction, they are all alike when they have once undergone this fermentative motion in its full extent. Nothing can then be obtained from them but phlegm, a volatile alkali, a fetid oil, and an insipid earth.

Almost all these changes are owing to the transmutation of the acid, which is depraved by putrefaction, and combined with a portion of the oil and subtilised earth of the mixt; so that the result of their union is a volatile alkali. Now, as the fixed alkali, found in the ashes of unputrefied plants, is only the most fixed part of their earth and of their acid, closely united together by the igneous motion, it is not surprising, that, when all the acid, with a part of the earth, is subtilised and volatilised by putrefaction, no fixed alkali can be found in the ashes of putrefied vegetables. The alteration which the acid suffers by the putrefactive motion is, in our opinion, the greatest it can undergo, without being entirely destroyed and decomposed, so as to be no longer a salt.

Of Operations on Animal Substances.

Of Milk.

Milk separated into Butter, Curd, and Whey; instanced in Cow's-Milk.

Put new cow's milk into a flat earthen pan, and set it in a temperate heat. In ten or twelve hours time there will gather on its surface a thick matter, of a somewhat yellowish white: this is called *cream*. Gently skim off this cream with a spoon, letting the milk you take up with it run off. Put all this cream into another vessel, and keep it. The milk thus skimmed will not be quite so thick as before; nor will it be of such a dead white, but have a little blueish cast. If all the cream be not separated from it, more will gather on its surface after some time, which must be taken off as the former. In two or three days the skimmed milk will coagulate into a soft mass called *curd*, and then it tastes and smells sour.

Cut this curd across in several places. It will immediately discharge a large quantity of *serum*. Put the whole into a clean linen cloth; hang it up, and underneath it set a vessel to receive the serum as it drops. When the aqueous part hath done dripping, there will remain in the filter a white substance somewhat harder than the curdled milk. This substance is called *cheese*, and the *serum* separated from it is known by the name of *whey*.

The milk of animals that feed only on vegetables is, of all animal matters, the least removed from the vegetable nature. The truth of this will be demonstrated by the experiments we shall produce by and by, for the further analysis of milk.

Most chemists justly consider milk as of the same nature with chyle. Indeed there is great reason to think, that, except some small differences to be afterwards taken notice of, these two matters are nearly the same. They are both of a dead white colour, like that of an emulsion; which proves that, like emulsions, they consist of an oily matter divided, diffused and suspended, but not perfectly dissolved, in an aqueous liquor.

It is not surprising that these liquors should resemble emulsions; for they are produced in the same manner, and may very justly be called *animal emulsions*. For how are vegetable substances converted into chyle and milk in an animal body? They are bruised, divided, and triturated by mastication and digestion, as perfectly, at least, as the matters pounded in a mortar to make an emulsion; and must thereby undergo the same changes as those matters; that is, their oily parts, being attenuated by those motions, must be mixed with and lodged between the aqueous parts, but not dissolved therein; because they do not, in the bodies of animals, meet with saline matters, sufficiently disentangled and active, to unite intimately with them, and by that means render them soluble in water.

Nevertheless, chyle and milk, though produced in the same manner as emulsions, and very much resembling them, differ greatly from them in some respects; owing chiefly to the time they remain in the bodies of animals, their being heated while there, the elaborations they undergo therein, and the animal juices commixed with them.

New milk hath a mild agreeable taste, without any saline pungency; nor hath any chemical trial discovered in it either an acid or an alkali. Yet it is certain, that the juices of plants, out of which milk is formed, contain many saline matters, and especially acids: accordingly milk also contains the same; but the acids are so sheathed and combined, that they are not perceplible. The case

is the ſame with all the other liquors intended to conſtitute part of an animal body: there is no perceptible acid in any of them.

Hence it may be inferred, that one of the principal changes which vegetables undergo, in order to their being converted into an animal ſubſtance, conſiſts in this, that their acids are combined, entangled, and ſheathed in ſuch a manner, that they become imperceptible, and exert none of their properties.

Milk left to itſelf, without the help of diſtillation, or any additament whavever, undergoes a ſort of decompoſition. It runs into a kind of ſpontaneous analyſis; which doth not indeed reduce it to its firſt principles, yet ſeparates it into three diſtinct ſubſtances, as the proceſs ſhews; namely, into cream, or the buttery fat part, into curd or cheeſe, and into ſerum or whey: which ſhews, that thoſe three ſubſtances of which milk conſiſts, are only mixed and blended together, but not intimately united.

The firſt parts, being the lighteſt, riſe gradually to the ſurface of the liquor as they ſeparate from the reſt: and this forms the cream.

Cream, as ſkimmed from the ſurface of milk, is not however the pure buttery or fat part; it is ſtill mixed with many particles of cheeſe and whey, which muſt be ſeparated in order to reduce it into butter. The moſt ſimple, and at the ſame time the beſt method of effecting this, is daily practiſed by the country people. It conſiſts in beating or churning the cream, in a veſſel contrived for that purpoſe, with the flat ſide of a circular piece of wood, in the centre of which a ſtaff is fixed. One would think that the motion, impreſſed one the cream by this inſtrument, ſhould rather ſerve to blend more intimately the particles of butter, cheeſe, and whey, of which it conſiſts, than to ſeparate them from each other; as this motion ſeems perfectly adapted to divide and attenuate thoſe particles. But, if we conſider what paſſes on this occaſion, we ſhall ſoon perceive that the motion by which butter is churned is nothing like triture: for churning is no other, properly ſpeaking, than a continually repeated compreſſion, the effect whereof is to ſqueeze out from amongſt the buttery particles thoſe of cheeſe and whey mixed therewith; by which means the particles of butter are brought into contact with each other, unite, and adhere together.

Milk, whether ſkimmed or no, grows ſour of itſelf, and curdles in a few days. When it is newly curdled, the cheeſe and whey ſeem to be united, and to make but one maſs: but theſe two matters ſeparate ſpontaneouſly from each other, with the greateſt eaſe, and in a very ſhort time.

The acidity, which milk naturally contracts in the ſpace of a few days, muſt be conſidered as the effect of a fermenting motion, which diſcovers in that liquor an acid that was not perceptible before. This, properly ſpeaking, is an acetous fermentation, which milk paſſes through in its way to putrefaction; and it ſoon follows, eſpecially if the milk be expoſed to a hot air.

If, inſtead of leaving milk to grow ſour and curdle of itſelf, an acid be mixed therewith, while it is yet ſweet and newly milked, it immediately coagulates; which gives reaſon to think, that its curdling naturally is the effect of the acid, which diſcovers itſelf therein as it grows ſtale.

The coagulation of milk may alſo be conſiderably accelerated, by ſetting it in a ſand-bath gently heated; or by mixing therewith a little of what, in the language of the dairy, is called *runnet*; which is nothing but ſome curdled and half-digeſted milk taken from the ſtomach of a calf: or both theſe methods may be employed at once, which will produce the effect ſtill more expeditiouſly.

It is not difficult to find out the cauſe of theſe effects. The runnet, which is milk already curdled and grown ſour, is an actual ferment to ſweet milk, diſpoſing it to turn ſour much more readily: for though milk, when thus haſtily curdled by the runnet, hath not a manifeſtly acid taſte, yet it is certain that this acid begins to exert itſelf. The proof thereof is, that, being expoſed to the ſame degree of heat with milk equally new, that is not mixed with this ferment, it turns ſour much ſooner. As to the effect of heat in coagulating milk, there is nothing extraordinary in it: we know how much it promotes and accelerates all fermentative motion. The whole of this perfectly agrees with what we ſaid before concerning fermentation.

Fixed alkalis alſo coagulate milk; but at the ſame time they ſeparate the whey from the cheeſe, which floats on the liquor in cloats. They give the milk a ruſſet colour inclining to red; which may ariſe from their attacking the fat part.

The ſeparation of milk into butter, cheeſe, and whey, is a kind of imperfect analyſis thereof, or rather the beginning of one. In order to render it complete, we muſt examine each of theſe ſubſtances ſeparately, and find the principles of which they conſiſt. This we ſhall endeavour to do in the following proceſs.

Butter analyſed by Diſtillation.

INTO a glaſs retort put the quantity of freſh butter you intend to diſtil. Set the retort in a reverberatory; apply a receiver; and let your fire be very gentle at firſt. The butter will melt, and there will come over ſome drops of clear water, which will have the peculiar ſmell of freſh butter, and ſhew ſome tokens of acidity. If the fire be increaſed a little, the butter will ſeem to boil: a froth will gather on its ſurface, and the phlegm, ſtill continuing to run, will gradually come to ſmell juſt like butter clarefied in order to be preſerved. Its acidity will be ſtronger and more manifeſt than that of the firſt drops that came over.

Soon after this, by encreaſing the fire a little more, there will riſe an oil, having nearly the ſame degree of fluidity as fat oils; but it will grow thicker as the diſtillation advances, and at laſt will fix in the receiver when it cools. It will be accompanied with ſome drops of liquor, the acidity whereof will always increaſe, while its quantity decreaſes, as the diſtillation advances.

While this thick oil is diſtilling, the butter contained in the retort, which at firſt ſeemed to boil, will be calm and ſmooth, without the leaſt appearance of ebullition; though the heat be then much greater than when it boiled. Continue the diſtillation, conſtantly increaſing the fire

fire by degrees as you find it neceſſary for the elevation of the thick oil. This oil, or rather this kind of butter, will be at laſt of a ruſſet colour. There will riſe along with it ſome white vapours exceeding ſharp and pungent.

When you obſerve that nothing more comes over, though the retort be quite red-hot, let the veſſels cool, and unlute them. You will find in the receiver an aqueous acid liquor, a fluid oil, and a kind of fixed brown butter. Break the retort, and you will find therein a kind of charred matter; the ſurface of which, where it touched the glaſs, will be of a ſhining black, and have a fine poliſh.

The analyſis of butter proves, that this ſubſtance, which is an oily matter in a concrete form, owes its conſiſtence to the acid only, with which the oily part is combined: that is, it follows the general rule frequently mentioned above in treating of other oily compounds; the conſiſtence whereof we ſhewed to be ſo much the firmer, the more acid they contain. The firſt portions of oil that come over in the diſtillation of butter are fluid, becauſe a pretty conſiderable quantity of acid roſe before them, which, being mixed with the phlegm, gives it the acidity we took notice of.

This oil, being freed from its acid, and by that means rendered fluid, riſes firſt; becauſe it is by the ſame means rendered lighter. The kind of butter that comes over afterwards, though it be fixed, is nevertheleſs far from having the ſame conſiſtence as it had before diſtillation; becauſe it loſes much of its acid in the operation. This acid is what riſes in the form of white vapours. Theſe vapours are at leaſt as pungent and irritating as the ſulphureous acid or volatile alkalis; but their ſmell is different: it hath a reſemblance, or rather is the ſame, with that which riſes from butter when it is burnt and browned in an open veſſel. But, when concentrated and collected in cloſe veſſels, as in the diſtillation of butter, they are vaſtly ſtronger; they irritate the throat ſo as to inflame it; they are exceeding ſharp and pungent to the ſmell, and are ſo hurtful to the eyes that they quickly inflame them, as in an ophthalmy, and and make them ſhed abundance of tears. The great volatility of this acid is entirely owing to a portion of the phlogiſton of the butter with which it is ſtill combined.

We took notice in the proceſs, that butter ſeems to boil with a very moderate heat at the beginning of the diſtillation, and that in the courſe of the operation the ebullition ceaſes entirely, though the heat be then greatly increaſed; which is contrary to the general rule. The reaſon is, that butter, though a ſeemingly homogeneous maſs, contains nevertheleſs ſome particles of cheeſe and whey. The particles of whey, being much the lighteſt, endeavour, on the firſt application of heat, to extricate themſelves from amongſt the particles of butter, and to riſe in diſtillation. Thus they form the drops of acidulated phlegm which come over at firſt, and, in ſtruggling to get free, lift up the buttery parts, or actually boil, which occaſions the ebullition obſervable at the beginning of the proceſs. When they are once ſeparated, the melted butter remains calm and ſmooth, without boiling. If you want to make it boil, you muſt apply a much greater degree of heat; which you cannot do in cloſe veſſels, without ſpoiling the whole operation: becauſe the degree of heat neceſſary for that purpoſe would force up the butter in ſubſtance, which would ruſh over into the receiver, without any decompoſition. Indeed if the veſſels were luted, they would be in danger of burſting.

As to the caſeous parts, which are mixed with freſh butter, they alſo ſeparate at the beginning of the diſtillation when the butter is melted, and gather on its ſurface in a ſcum. Theſe particles of cheeſe and whey, which are heterogeneous to butter, help to make it ſpoil the ſooner. And for this reaſon, thoſe who want to keep butter a long time, without the uſe of ſalt, melt it, and thereby evaporate the aqueous parts. The lighteſt portion of the particles of cheeſe riſes to the ſurface, and is ſkimmed off; the reſt remains at the bottom of the veſſel, from which the butter is eaſily ſeparated, by decanting it while it is yet fluid.

Butter may alſo be diſtilled, by incorporating it with ſome additament which will yield no principle itſelf, nor retain any of thoſe of the butter. It may be diſtilled in this manner with the additament of fine ſand: the operation ſucceeds very well, is ſooner finiſhed, and more eaſily conducted.

If you deſire to convert the butter wholly into oil, you muſt take the fixed matter you find in the receiver, and diſtil it once more, or oftener, according to the degree of fluidity you want to give it. The caſe is the ſame with this matter as with all other thick oils, which, the oftener they are diſtilled, grow always the more fluid, becauſe in every diſtillation they are ſeparated from part of the acid, to which alone they owe their conſiſtence.

The Curd of Milk analyſed by Diſtillation.

INTO a glaſs retort put ſome new curd, having firſt drained it thoroughly of all its whey, and even ſqueezed it in a linen cloth to expreſs all its moiſture. Diſtil it as you did butter. There will come over at firſt an acidulated phlegm, ſmelling like cheeſe or whey. As the diſtillation advances, the acidity of this phlegm will increaſe.

When it begins to run but very ſlowly, raiſe your fire. There will come over a yellow oil, ſomewhat empyreumatic. Continue the diſtillation, ſtill increaſing the fire by degrees as occaſion requires. The oil and acid phlegm will continue to riſe; the phlegm growing gradually more acid, and the oil deeper coloured and more empyreumatic. At laſt, when the retort is almoſt red-hot, there comes off a ſecond black oil, of the conſiſtence of turpentine, very empyreumatic, and ſo heavy as to ſink in water. In the retort will be left a conſiderable quantity of charred matter.

Cheeſe curd barely drained, till no more whey will drip from it, is not entirely freed thereof; and for this reaſon we directed it to be preſſed in a linen cloth, before it be put into the retort to be diſtilled. Without this precaution, the remaining whey would riſe in a conſiderable quantity on the firſt application of heat; and, inſtead of analyſing the curd only, we ſhould at the ſame time analyſe the whey alſo. This is to be underſtood of green curd and new-made cheeſe; for, if it be ſuffered to grow old,

old, it will at length dry of itſelf: but then we ſhould not obtain from it the ſame principles by diſtillation; as it corrupts and begins to grow putrid after ſome time, eſpecially if it be not mixed with ſome ſeaſoning to preſerve it.

The firſt phlegm that riſes in this diſtillation, as in that of butter, is a portion of the whey that was left in the cheeſe, notwithſtanding its being well preſſed. This phlegm grows gradually more acid, being the vehicle of the acids of the cheeſe, which are forced up along with it by the fire.

The acid obtained from this matter is leſs in quantity, and weaker, than that of butter: and accordingly the oil diſtilled from cheeſe is not fixed like that of butter. Yet it is remarkable that the laſt empyreumatic oil, which is as thick as turpentine, is heavier than water: a property which it probably derives from the quantity of acid it retains.

The quantity of charred matter, which remains in the retort after the diſtillation of cheeſe, is much greater than that left by butter: which proves that the former contains a much greater quantity of earth.

Whey analyſed.

Evaporate two or three quarts of whey almoſt to dryneſs in a *balneum mariæ*; and diſtil the extract or reſiduum in a retort ſet in a reverberating furnace, with degrees of fire, according to the general rule. At firſt ſome phlegm will come over; then a lemon-coloured acid ſpirit; and afterwards a pretty thick oil. There will remain in the retort a charred matter, which being expoſed to the air grows moiſt. Lixiviate it with rain water, and evaporate the lixivium; it will yield you cryſtals of ſea-ſalt. Dry the charred matter, and burn it in the open air with a ſtrong fire, till it be reduced into aſhes. A lixivium of theſe aſhes will ſhew ſome tokens of a fixed alkali.

It will appear, on examining the three analyſes of the the ſubſtances whereof milk conſiſts, that none of them yields a volatile alkali: which is worthy of notice; as it is the only animal matter from which ſuch a ſalt cannot be obtained. It is true, the milk of animals that feed on vegetables may be conſidered as an intermediate liquor between vegetable and animal ſubſtances; as an imperfect animal-juice, which ſtill retains much of the vegetable nature: and we actually find, that milk almoſt always hath, at leaſt in part, the properties of thoſe plants with which the animals that yield it are fed. Yet, as it cannot be formed in the body of the animal, without mixing with ſeveral of its juices that are entirely perfected, and become purely animal, it muſt appear ſtrange that the analyſis thereof ſhould not afford the leaſt veſtige of that principle, which all other animal-matters yield in the greateſt plenty.

The reaſon of this may be found in the uſe to which milk is deſtined. It is intended for the nouriſhment of animals of the ſame ſpecies with thoſe in whoſe bodies it is produced. Conſequently it ought as much as poſſible to reſemble the juices of the food which is proper for thoſe animals. Now, as animals that live only on vegetables could not be properly nouriſhed by animal matters, for which nature itſelf hath even given them an averſion, it is not ſurpriſing that the milk of ſuch animals ſhould be free from any mixture of ſuch things as are unſuitable to the young ones whom it is deſigned to nouriſh. There is reaſon therefore to think, that nature hath diſpoſed the organs in which the ſecretion of milk is performed, ſo as to ſeparate it entirely from all the animal juices firſt mixed with it: and this is the principal difference between milk and chyle; the latter being neceſſarily blended with the ſaliva, the gaſtric and pancreatic juices, the bile and lymph, of the animals in which it is formed. Hence it may be concluded, that, if a quantity of chyle could be collected ſufficient to enable us to analyſe it, the analyſis thereof would differ from that of milk, in this chiefly, that it would yield a great deal of volatile alkali, of which milk, as hath been ſaid, yields none at all.

The ſame thing probably takes place in carnivorous animals. It is certain, that thoſe animals chuſe to eat the fleſh of ſuch others only as feed upon vegetables; and that nothing but extreme hunger, and the abſolute want of more agreeable food, will force them to eat the fleſh of other carnivorous animals. Wolves, which greedily devour ſheep, goats, &c. ſeldom eat foxes, cats, polecats, &c. though theſe animals are not ſtrong enough to reſiſt them. Foxes, cats, and birds of prey, that make ſuch terrible havock among wild-fowl, and other ſorts of game, do not devour one another. This being laid down, there is reaſon to think, that the milk of carnivorous animals is ſomething of the nature of the fleſh of thoſe animals that feed on vegetables, and which they chuſe to eat, and not of the nature of their own fleſh; as the milk of animals that feed on vegetables is analogous to the juices of vegetables, and when analyſed yields no volatile alkali, though every other part of their body does.

But whatever be the nature of milk, and of whatever ingredients it be formed, it always contains the three ſeveral ſubſtances above mentioned; namely, the fat, or buttery part, properly ſo called, the cheeſy, and the ſerous part, the laſt of which we are now to examine. It is, properly ſpeaking, the phlegm of the milk, and conſiſts almoſt entirely of water. For this reaſon it is proper to leſſen the quantity thereof conſiderably by evaporation, ſo that its other principles, being concentrated and brought nearer together, may become much more ſenſible. There is no danger of loſing any eſſential part of the whey in the evaporation, if it be performed in the *balneum mariæ* with ſuch a gentle heat as may carry off the aqueous parts only: this greatly ſhortens the analyſis, which will be exceeding long and tedious if all the water be diſtilled off in cloſe veſſels.

As whey is chiefly the aqueous part of milk, as ſaid above, it muſt contain all the principles thereof that are ſoluble in water; that is, its ſaline and ſaponaceous parts. And accordingly the analyſis thereof ſhews that it contains an oil, rendered perfectly ſaponaceous by an acid; that is, made perfectly miſcible with water. This quality of the oil contained in whey appears from the perfect tranſparency of that liquor, which we know is the

the mark of a complete diffolution. In the diftillation of whey, the faponaceous matter contained therein is decompofed; the faline part rifes firft, as being the lighteft; this is the acid taken notice of in the procefs; after which the oil, now feparated from the principle which rendered it mifcible with water, comes over in its natural form, and doth not afterwards mix with the aqueous part.

Befides the faponaceous matter, whey contains alfo another faline fubftance; namely, fea falt: this is obtained by lixiviating the *caput mortuum* left in the retort, which, becaufe of its fixednefs, cannot rife with the other principles in diftillation. To this falt it is owing that what remains in the retort after diftillation grows moift in the air; for we know that fea-falt thoroughly dried hath this property.

The fixed alkaline falt, obtained from the *caput mortuum* burnt to afhes, proves that milk ftill retains fomething of the vegetable nature: for the following analyfis will fhew us that matters purely animal yield none at all.

Of the Subftances which compofe an Animal Body.

Blood analyfed. Inftanced in Bullock's Blood.

In a *balneum mariæ* evaporate all the moifture of the blood that the heat of boiling water will carry off. There will remain an almoft dry matter. Put this dried blood into a glafs retort, and diftil with degrees of heat, till nothing more will come over, even when the retort is quite red-hot, and ready to melt. A brownifh phlegm will rife at firft: this will foon be impregnated with a little volatile alkali, and then will come over a yellow oil, a very pungent volatile fpirit, a volatile falt in a concrete form, which will adhere to the fides of the receiver; and, at laft, a black oil, as thick as pitch. There will be left in the retort a charred matter, which being burnt yields no fixed alkali.

Blood, which is carried by the circulation into all the parts of the animal body, and furnifhes the matter of all the fecretions, muft be confidered as a liquor confifting of almoft all the fluids neceffary to the animal machine: fo that the analyfis thereof is a fort of general though imperfect analyfis of an animal.

Blood drawn from the body of an animal, and fet by in a veffel, coagulates as it grows cold; and fometimes afterwards the *coagulum* difcharges a yellowifh *ferum* or lymph; and in the midft thereof fwims the red part, which continues curdled. Thefe two fubftances, when analyfed, yield nearly the fame principles; and in that refpect feem to differ little from each other. Though the ferum of blood be naturally in a fluid form, yet it hath alfo a great tendency to coagulate; and a certain degree of heat applied to it, either by water or by a naked fire, will curdle it. Spirit of wine mixed with this liquor produces on it the fame effect as heat.

Blood, while circulating in the body of a healthy animal, and when newly taken from it, hath a mild tafte, which difcovers nothing like either an acid or an alkali; nor doth it fhew any fign of either the one or the other in chemical trials. When tafted with attention, it betrays fomething like a favour of fea-falt; becaufe it actually contains a little thereof, which is found in the charred matter left in the retort after the diftillation, when carefully examined.

We fhewed that milk alfo contains a little of this falt. It enters the bodies of animals with the food they eat, which contains more or lefs thereof according to its nature. It plainly fuffers no alteration by undergoing the digeftions, and paffing through the ftrainers, of the animal body. The cafe is the fame with the other neutral falts which have a fixed alkali for their bafis: we find them unchanged in the juices of animals into whofe bodies they have been introduced. They are incapable of combining, as acids do, with the oilly parts; and fo are diffolved by the aqueous fluids, of which nature makes ufe to free herfelf from thofe falts, and difcharge them out of the body.

Blood, like all other animal-matters, is, properly fpeaking, fufceptible of no fermentation but that of putrefaction. Yet it turns fomewhat four before it putrefies. This fmall degree of acetous fermentation is moft fenfible in flefh; and efpecially in the flefh of young animals, fuch as calves, lambs, chickens, &c.

The quantity of pure water, which blood, in its natural ftate, contains, is very confiderable, and makes almoft feven eighths thereof. If it be diftilled, without being firft dried, the operation will be much longer; becaufe it will be neceffary to draw off all this infipid phlegm with a gentle fire. There is no reafon to apprehend that, by drying blood in open veffels as directed, any of its other principles will be carried off with its phlegm: for it contains no other fubftance that is volatile enough to rife with the warmth of a *balneum mariæ*. This may be proved by putting fome undried blood into a glafs cucurbit, fitting thereto a head and receiver, and diftilling, in a *balneum mariæ*, all that the heat of the bath, not exceeding the heat of boiling water, will raife: for, when nothing more will come over, you will find in the receiver an infipid phlegm only, fcarce differing from pure water, except in having a faint fmell like that of blood; wherein it refembles all the phlegms that rife firft in diftillation, which always retain fomething of the fmell of the matters from which they were drawn. That part of the blood, which remains in the cucurbit after this firft diftillation, being put into a retort, and diftilled with a ftronger fire, yields exactly the fame principles, and in the fame proportion, as blood dried in open veffels in the *balneum mariæ*: fo that, if this phlegm of blood contains any principles, the quantity thereof is fo fmall as to be fcarce perceptible.

The volatile alkali that rifes with the oil, when blood is diftilled in a retort with a degree of heat greater than that of boiling water, is either the production of the fire, or arifes from the decompofition of an ammoniacal falt of which it made a part. For we fhall fee, when we come to treat of this faline fubftance, that it is fo extremely volatile as to exceed, in that refpect, almoft all other bodies that we know: and therefore if this volatile alkali pre-exifted formerly in the blood, uncombined with any other matter capable, in fome meafure, of

of fixing it, it would rise at first almost spontaneously, or at least on the first application of the gentlest heat. We have an instance of this in blood, or any other animal-matter, that is perfectly putrefied; which containing a volatile alkali, either formed or extricated by putrefaction, lets go this principle when distilled, even before the first phlegm: and, for this reason, when putrefied blood is to be analysed, it must by no means be dried, like fresh blood, before distillation; for all the volatile alkali would by that means be dissipated and lost at once.

Though blood and other animal matters afford no fixed alkali, but, on the contrary, yield much volatile alkali, it doth not therefore follow that all the acid, which those substances contained before they were analysed, is employed in the production of a volatile alkali.

Flesh analysed. Instanced in Beef.

INTO an alembic or retort, placed in a sand-bath, put some lean beaf, from which you have carefully separated all the fat. Distil till nothing more will rise. In this first distillation a phlegm will come over, weighing at least half the mass of the distilled flesh. In the retort you will find a matter almost dry, which you must afterwards distil with a naked fire in a reverberating furnace, taking the usual precautions. There will come over at first a little phlegm replete with volatile alkali; then a volatile alkali in a dry form, which will stick to the sides of the vessel; and also a thick oil. After the distillation there will be left in the retort a black, shining, light coal. Burn it to ashes in the open air, and lixiviate those ashes: the water of the lixivium will have no alkaline property, but will shew some tokens of its containing a little sea-salt.

The flesh of an animal, as appears from the process, yields much the same principles with its blood: and it cannot be otherwise; because it is formed altogether of materials furnished by the blood.

Bones analysed. Instanced in Ox-Bones.

CUT into pieces the bones of a leg of beef, carefully separating all the marrow. Put them into a retort, and distil them in a reverberating furnace as usual. A phlegm will come over first; then a volatile spirit, which will become stronger and stronger; afterwards a volatile salt in a dry form, with some oil; and, lastly, a black oil, with a little more volatile salt. There will be left in the retort a charred matter, from which a little sea-salt may be extracted. Reduce this charred matter to ashes, by burning it in the open air. These ashes will give some slight tokens of a fixed alkali.

The analysis of bones proves, that they consist of the same principles with flesh and blood; and the same may be said in general of all matters that are truly animal, that actually constitute any part of an animal.

Animal Fat Analysed. Instanced in Mutton-Suet.

PUT as much mutton-suet as you please into a glass retort, only taking care that the vessel be but half full; and distil with degrees of fire as usual. A phlegm smelling of the suet will rise first, and soon grow very acid. After this some drops of oil will come over, and be followed by a matter like oil, in appearance, when it comes over; but it will fix in the receiver, and acquire a consistence somewhat softer than suet. This kind of butter of suet will continue to rise to the end of the distillation; and there will be left in the retort a small quantity of charred matter.

Eggs analysed. Instanced in Pullet's Eggs.

PUT some hens eggs in water, and boil them till they be hard. Then separate the yolks from the whites. Cut the whites into little bits; put them into a glass cucurbit; fit on a head and receiver; distil in a *balneum mariæ* with degrees of fire, raising it towards the end to the strongest heat which that bath can give; that is, to the heat of boiling water. There will come over an aqueous liquor, or insipid phlegm; the quantity whereof will be very considerable seeing it will make about nine tenths of the whole mass of the whites of the eggs. Continue your distillation, and keep the water in the bath constantly boiling, till not a drop more of liquor will ascend from the alembic. Then unlute your vessels. In the cucurbit you will find your whites of eggs considerably shrunk in their bulk. They will look like little bits of brown glass, and be hard and brittle.

Put this residuum into a glass retort, and distil, as usual, in a reverberating furnace with degrees of heat. There will come over a volatile oily spirit, a yellow oil, a volatile salt in a dry form, and, at last, a black thick oil. There will be left in the retort a charred matter.

Reduce also into the smallest pieces you can the hard yolks of the eggs which you separated from the whites. Set them in a pan over a gentle fire: stir them with a stick till they turn a little brown, and discharge a substance like melted marrow. Then put them into a new, strong, canvass bag, and press them between two iron plates well heated; whereby you will obtain a considerable quantity of a yellow oil.

Let what remains in the bag be distilled in a retort set in a reverberating furnace: it will give you the same principles as you got from the whites.

Of the two perfectly distinct substances that constitute the egg, the yolk contains the embryo of the chick, and is destined to hatch it: the white is to serve for the nourishment of the chick when it is formed.

These two matters, though they contain the very same principles, yet differ considerably from each other; and chiefly in this, that their principles are not in the same proportions.

The white of an egg contains so much phlegm, that it seems to consist almost totally thereof. All the aqueous liquor, obtained by distilling it in the *balneum mariæ*, is, properly speaking, nothing but pure water; for no chemical trial can discover in it either an acid or a volatile alkali; or any very perceptilbe oily part. And yet it must contain some oil, because the liquor that rises last is a little bitterish to the taste, and smells somewhat of empyreuma. But the principles from which it derives these properties are in too small quantities to be distinctly perceived.

If,

If, inſtead of diſtilling the hard white of an egg, with a view to draw off the great quantity of water it contains, you leave it ſome time in an air that is not too dry, the greateſt part of its moiſture ſeparates ſpontaneouſly, and becomes very ſenſible. In all probability this is the effect of a beginning putrefaction, which attenuates this ſubſtance, and breaks its contexture. The liquor thus diſcharged by the white of an egg thoroughly diſſolves the gum-reſins, and particularly myrrh. If you deſire to diſſolve myrrh in this manner, cut a hard-boiled egg in halves; take out the yolk; put the powdered gum-reſin into the cavity left by the yolk; join the two halves of the white; faſten them together with a thread, and hang them up in a cellar. In a few days time the myrrh will be diſſolved by the moiſture that iſſues from the white of the egg, and will drop into the veſſel placed underneath to receive it. This liquor is improperly called *oil of myrrh per deliquium.*

All the properties of the whites of eggs, as well as the principles obtained by analyſing them, are the ſame with thoſe of the lymphatic part of the blood; ſo that there is a great reſemblance between theſe two ſubſtances.

As to the yolk, it is plain from its analyſis, that oil is the predominant principle thereof. If the yolk of an egg be mixed with water, the oil with which it is replete, and which is by nature very minutely divided, diffuſes eaſily through the whole liquor, and remains ſuſpended therein by means of its viſcoſity. The liquor at the ſame time becomes milk-white like an emulſion, and is in fact a true animal emulſion.

In order to obtain the oil of eggs by expreſſion with the more eaſe, care muſt be taken to chuſe eggs that are ſeven or eight days old; becauſe they are then a little leſs viſcous. Nevertheleſs their viſcoſity is ſtill ſo great, that they will not eaſily yield their oil by expreſſion: and therefore, in order to attenuate and deſtroy entirely this viſcoſity, they muſt be torrefied before they are put to be preſſed.

The oil of eggs, like all other oily animal matters, ſeems analogous to the fat oils of vegetables. It hath all the properties that characteriſe thoſe oils. Its colour is yellow, and it ſmells and taſtes a little of the empyreuma, occaſioned by torrefying the yolks. It is rendered ſomewhat leſs diſagreeable by being expoſed to the dew for thirty or forty nights, if care be taken to ſtir it often in the mean time.

To conclude: all the principles both in the yolk and the white of an egg are the ſame as thoſe found in blood, fleſh, and all other matters that are perfectly animal.

Of the Excrements of Animals.

Dung analyſed. Inſtanced in human Excrements. Mr Homberg's Phoſphorus.

Take any quantity you pleaſe of human excrement, and diſtil it in a glaſs alembic ſet in the *balneum mariæ.* You will obtain an aqueous, clear, inſipid liquor; which will nevertheleſs have a diſagreeable odour. Having urged the diſtillation as far as is poſſible with the heat of this bath, unlute your veſſels, and you will find at the bottom of the cucurbit a dry matter, making about an eighth part only of what you put into it. Put this reſiduum into a glaſs retort, and diſtil in a reverberating furnace, with degrees of heat. You will obtain a volatile ſpirit, and a volatile ſalt, with a fetid oil; and a charred matter will be left in the retort.

This ſubſtance, conſiſting of matters ſubject to putrefaction, hath conſtantly a fetid ſmell, like that of all putrid matters; having been for ſome time confined in a warm, moiſt place, which we know promotes putrefaction, and even quickly produces it. Yet the analyſis thereof proves that it is not putrefied, or at leaſt not entirely ſo: for all putrefied matters contain a volatile alkali perfectly formed and extricated; and, as this principle riſes with leſs heat than that of boiling water, it always comes over firſt in diſtillation. Now we have ſeen that, with the heat of boiling water, it parts with nothing but an inſipid phlegm, containing no volatile alkali: a ſure proof that the fecal matter is not completely putrefied.

One of the methods by which Mr Homberg endeavoured to obtain from excrement a clear oil, without any bad ſmell, was to ſeparate its earthy and groſs parts, by filtering it before he diſtilled it. "For this purpoſe he diluted excrement newly diſcharged with hot water, uſing a quart of water to an ounce of feces. Then he let the mixture ſtand to cool, and the groſs parts falling to the bottom, he poured off the water by inclination. This liquor he filtered through brown paper, and evaporated to a pellicle over a gentle fire. There ſhot in it long cryſtals of four, five, and ſix ſides, which Mr Homberg thinks may be called the eſſential ſalt of excrement. They reſemble ſalt petre, in ſome meaſure, and deflagrate in the fire much like it; with this difference, that their flame is red, and they burn ſlowly; whereas the flame of ſalt-petre is white and very vivid: probably, ſays Mr Homberg, becauſe there is too much of an oily matter in the one, and leſs in the other.

"Mr Homberg diſtilled this ſalt in a glaſs retort with degrees of fire, and at laſt with a very violent one. At firſt there came over an aqueous liquor, ſharp and acid, which was followed by a brown fetid oil, ſmelling very ſtrong of empyreuma. This diſtillation he attempted four ſeveral times; and each time the matter in the retort took fire, juſt when the oil began to come off."

The ſalt which Mr Homberg obtained from excrement is very remarkable. Its nitrous character is by no means ambiguous: its deflagrating on live coals convinced Mr Homberg of its being a true nitre. But its conſtantly taking fire in the retort, as oft as diſtilled, is a ſure proof that it is a nitrous ſalt: for nitre only hath the property of thus taking fire in cloſe veſſels, and making other combuſtible matters burn along with it.

The proceſs, by which Mr Homberg at laſt obtained from excrement a clear oil without any bad ſmell, is curious, and worthy of a place here, on account of the views and occaſions of reflection which it may open.

"Mr Homberg having tried in vain, by diſtilling excrement a great many different ways, to obtain from it ſuch an oil as he wanted, reſolved to employ fermenta-

tion, the effect whereof is to change the diſpoſition of the principles of mixts. With this view he dried ſome excrement in the water-bath, and, having pulveriſed it, poured thereon ſix times its weight of phlegm that had been ſeparated from it by diſtillation, and put the whole into a large glaſs cucurbit, covered with an inverted veſſel that fitted exactly into it, and was cloſe luted. This veſſel he ſet in a *balneum mariæ* for ſix weeks, keeping up ſuch a gentle heat as would not burn one's hand; after which he uncovered the cucurbit, and having fitted thereto a head and a receiver, diſtilled off all the aqueous moiſture in the *balneum mariæ* with a very gentle heat. It had now loſt almoſt all its bad ſmell, which was changed into a faint one. It came over ſomewhat turbid, whereas it was very clear when put into the cucurbit. Mr Homberg found this water to have a coſmetic virtue: he gave ſome of it to perſons whoſe complexion, neck, and arms, were quite ſpoiled, being turned brown, dry, rough, and like a gooſe ſkin: they waſhed with it once a day, and, by continuing the uſe of this water, their ſkin became very ſoft and white.

" The dry matter left in the cucurbit after the firſt diſtillation, had not the leaſt ſmell of feces: on the contrary, it had an agreeable aromatic odour; and the veſſel in which Mr Homberg had digeſted it, being left open in a corner of his laboratory, acquired in time a ſtrong ſmell of ambergris. It is ſurpriſing, as Mr Homberg juſtly obſerves, that digeſtion alone ſhould change the abominable ſmell of excrement into an odour as agreeable as that of ambergris.

" This dry matter he powdered coarſely, and put two ounces thereof at once into a glaſs retort that would hold about a pound or a pound and a half of water. This he diſtilled in a ſand-bath with a very gentle heat. A ſmall quantity of an aqueous liquor came over firſt, and then an oil as colourleſs as ſpring-water. Mr Homberg continued the ſame gentle degree of heat till the drops began to come off a little rediſh; and then he changed the receiver, ſtopping that which contained the clear oil very cloſe with a cork. Having carried on the diſtillation with a fire gradually augmented, there came over a conſiderable quantity of red oil; and there remained in the retort a charred matter which burnt very readily."

The clear oil, without any ill ſmell, which Mr Homberg obtained from the fecal matter by this proceſs, was the very thing he was in ſearch of, and which he had been aſſured would convert mercury into fine fixed ſilver; yet he ingenuouſly owns, that, whatever way he applied it, he could never produce any change in that metallic ſubſtance. We ſhall now proceed to the other diſcoveries made by Mr Homberg on this occaſion.

In his attempt to obtain a clear oil from excrement, he diſtilled it with different additaments, and amongſt the reſt with vitriol and alum. He found that the matters left in the retort, when he made uſe of theſe ſalts, being expoſed to the open air, took fire of themſelves; that they kindled combuſtible matters; in a word, that they were a true phoſphorus, of a ſpecies different from all then known. Purſuing theſe firſt hints, he ſought and found the means of preparing this phoſphorus by a way much more expeditious, certain, and eaſy. His proceſs is this.

" Take four ounces of feces newly excreted: mix therewith an equal weight of roch alum coarſely powdered: put the whole into a little iron pan that will hold about a quart of water, and ſet it over a gentle fire under a chimney. The mixture will melt, and become as liquid as water. Let it boil with a gentle fire, conſtantly ſtirring it, breaking it into little crumbs, and ſcraping off with a ſpatula whatever ſticks to the bottom or ſides of the pan, till it be perfectly dry. The pan muſt from time to time be removed from the fire, that it may not grow red hot; and the matter muſt be ſtirred, even while it is off the fire, to prevent too much of it from ſticking to the pan. When the matter is perfectly dried, and in little clots, let it cool, and powder it in a metal mortar. Then put it again into the pan, ſet it over the fire, and ſtir it continually. It will again grow a little moiſt, and adhere together in clots, which muſt be continually roaſted and bruiſed till they be perfectly dry; after which they muſt be ſuffered to cool, and then be pulveriſed. This powder muſt be returned a third time to the pan, ſet on the fire, roaſted, and perfectly dried: after which it muſt be reduced to a fine powder, and kept in a paper in a dry place. This is the firſt or preparatory operation.

" Take two or three drams of this powder. Put it into a little matras, the belly of which will hold an ounce, or an ounce and half of water, and having a neck about ſix or ſeven inches long. Order it ſo that your powder ſhall take up no more than about a third part of the matras. Stop the neck of the matras ſlightly with paper: then take a crucible four or five inches deep: in the bottom of the crucible put three or four ſpoonfulls of ſand: ſet the matras on this ſand, and in the middle of the crucible, ſo as not to touch its ſides. Then fill up the crucible with ſand, ſo that the belly of the matras may be quite buried therein. This done, place your crucible with the matras in the midſt of a little earthen furnace, commonly called a *ſtove*, about eight or ten inches wide above, and ſix inches deep from the mouth to the grate. Round the crucible put lighted coals about half way up, and when it hath ſtood thus half an hour, fill up with coals to the very top of the crucible. Keep up this fire a full half hour longer, or till you ſee the inſide of the matras begin to be red. Then increaſe your fire, by raiſing your coals above the crucible. Continue this ſtrong heat for a full hour, and then let the fire go out.

" At the beginning of this operation denſe fumes will riſe out of the matras, through the ſtopple of paper. Theſe fumes iſſue ſometimes in ſuch abundance as to puſh out the ſtopple; which you muſt then replace, and ſlacken the fire. The fumes ceaſe when the inſide of the matras begins to grow red; and then you may increaſe the fire without any fear of ſpoiling your operation.

" When the crucible is ſo cold that it may be ſafely taken out of the furnace with one's hand, you muſt gradually draw the matras out of the ſand, that it may cool ſlowly, and then ſtop it cloſe with a cork.

" If the matter at the bottom of the matras appear to be

be in powder when ſhaken, it is a ſign the operation hath ſucceeded: but if it be in a cake, and doth not fall into powder on ſhaking the matras, it ſhews that your matter was not ſufficiently roaſted and dried in the iron pan during the preparatory operation."

Mr Lemeri hath ſhewn, that excrement is not the only matter capable of producing this phoſphorus with alum; but that, on the contrary, almoſt all animal and even vegetable matters are fit for this combination; that though Mr Homberg mixed alum in equal quantities only with the fecal matter, it may be uſed in a much greater proportion, and, in certain caſes, will ſucceed the better; that, according to the nature of the ſubſtances to be worked on, the quantity of that ſalt may be more or leſs increaſed; and that whatever is added, more than the doſe requiſite for each matter, ſerves only to leſſen the virtue of the phoſphorus, or even deſtroys it entirely; that the degree of fire applied muſt be different according to the nature of thoſe matters; and, laſtly, that ſalts containing exactly the ſame acid with that of alum, or the acid of thoſe ſalts ſeparated from its baſis and reduced into ſpirit, do not anſwer in the preſent operation: which ſhews, ſays Mr Lemeri, that many ſulphureous matters may be ſubſtituted for excrement in this operation; but that there are no ſalts, or very few, if any, that will ſucceed in the place of alum.

This phoſphorus, made either by Mr Homberg's or by Mr Lemeri's method, ſhines both by day and by night. Beſides emitting light, it takes fire ſoon after it is expoſed to the air, and kindles all combuſtible matters with which it comes in contact; and this without being rubbed or heated.

Meſſ. Homberg and Lemeri have given the moſt probable and the moſt natural explanation of the cauſe of the accenſion and other phenomena of this phoſphorus. What they ſay amounts in ſhort to what follows.

Alum is known to be a neutral ſalt, conſiſting of the vitriolic acid and a calcareous earth. When this ſalt is calcined with the fecal matter, or other ſubſtances abounding in oil, the volatile principles of theſe ſubſtances, ſuch as their phlegm, their ſalts, and their oils, exhale in the ſame manner as if they were diſtilled; and there is nothing left in the matras, when thoſe principles are diſſipated, but a charred matter, like that which is found in retorts wherein ſuch mixts have been decompoſed by diſtillation.

This remainder therefore is nothing but a mixture of alum and charcoal. Now, as the acid of this ſalt, which is the vitriolic, hath a greater affinity with the phlogiſton than with any other ſubſtance, it will quit its baſis to unite with the phlogiſton of the coal, and be converted by that union into a ſulphur. And this is the very caſe, of which we have certain proofs in the operation for preparing this phoſphorus; for when, after the volatile principles of the oily matter are drawn off, the fire is increaſed, in order to combine cloſely together the fixed parts that remain in the matras, that is, the alum and the charred matter, we perceive at the mouth of the matras a ſmall blue ſulphureous flame, and a pungent ſmell of burning ſulphur. Nay, when the operation is finiſhed, we find a real ſulphur ſticking in the neck of the matras; and, while the phoſphorus is burning, it hath plainly a ſtrong ſulphureous ſmell. It is therefore certain, that this phoſphorus contains an actual ſulphur; that is, a matter diſpoſed to take fire with the greateſt eaſe. But though ſulphur be very inflammable, it never takes fire of itſelf, without being either in contact with ſome matter that is actually ignited, or elſe being expoſed to a conſiderable degree of heat. Let us ſee then what may be the cauſe of its accenſion, when it is a conſtituent part of this phoſphorus.

We mentioned juſt now, that the acid of the alum quits its baſis, in order to form a ſulphur by combining with the phlogiſton of the coal. This baſis we know to be an earth capable of being converted into lime; and that it is actually converted into quick-lime by the calcination neceſſary to produce the phoſphorus. We know that new made lime hath the property of uniting with water ſo readily, that it thereby contracts a very great degree of heat. Now when this phoſphorus, which is partly conſtituted of the baſis of the alum converted into quick-lime, is expoſed to the air, the lime inſtantly attracts the moiſture of which the air is always full, and by this means, probably, grows ſo hot as to fire the ſulphur with which it is mixed. Perhaps alſo the acid of the alum is not totally changed into ſulphur: ſome part thereof may be only half-diſengaged from its baſis, and in that condition be capable of attracting ſtrongly the humidity of the air, of growing very hot likewiſe by imbibing the moiſture, and ſo of contributing to the accenſion of the phoſphorus.

There is alſo room to think that all the phlogiſton of the charred matter is not employed in the production of ſulphur in this phoſporus, but that ſome part of it remains in the ſtate of a true coal. The black colour of the unkindled phoſphorus, and the red ſparkles it emits while burning, ſufficiently prove this.

Human Urine analyſed.

Put ſome human urine into a glaſs alembic; ſet it in a water-bath, and diſtil till there remain only about a fortieth part of what you put in; or elſe evaporate the urine in a pan ſet in the *balneum mariæ* till it be reduced to the ſame quantity. With this heat nothing will exhale but an inſipid phlegm, ſmelling however like urine. The reſiduum will, as the evaporation advances, become of a darker and darker ruſſet, and at laſt acquire an almoſt black colour. Mingle this reſiduum with thrice its weight of ſand, and diſtil it in a retort ſet in a reverberating furnace, with the uſual precautions. At firſt there will come over a little more inſipid phlegm like the former. When the matter is almoſt dry, a volatile ſpirit will riſe. After this ſpirit, white vapours will appear on increaſing the fire: a yellow oily liquor will come off, trickling down in veins; and together with this liquor a concrete volatile ſalt, which will ſtick to the ſides of the receiver. At laſt there will come over a deep-coloured fetid oil. In the retort there will remain a ſaline earthy reſiduum, which being lixiviated will yield ſome ſea-ſalt.

Of

Of the Volatile Alkali.

Volatile Alkalis rectified and depurated.

Mix together the ſpirit, the volatile ſalt, the phlegm, and the oil, obtained from any ſubſtance whatever. Put the whole into a large wide-mouthed glaſs body, and thereto fit a head with a large beak. Set this alembic in a water-bath, lute on a receiver, and diſtil with a very gentle heat. There will aſcend a ſpirit ſtrongly impregnated with volatile alkali, and a volatile ſalt in a concrete form, which muſt be kept by itſelf. Then increaſe your heat to the degree of boiling water; whereupon there will riſe a ſecond volatile ſpirit, ſomewhat more ponderous than the former, with a light oil that will ſwim on its ſurface, and a little concrete volatile ſalt. Proceed till nothing more will riſe with this degree of heat. Keep by itſelf what came over into the receiver. At the bottom of the cucurbit you will find a thick fetid oil.

Into ſuch another diſtilling veſſel put the ſpirit and ſalt that roſe firſt in this diſtillation, and diſtil them in the *balneum mariæ* with a heat ſtill gentler than before. A whiter, purer, volatile ſalt will ſublime. Continue the diſtillation till an aqueous moiſture riſe, which will begin to diſſolve the ſalt. At the bottom of the veſſel will be left a phlegm, with a little oil floating on it. Keep your ſalt in a bottle well ſtopped.

Volatile Alkalis combined with Acids. Sundry Ammoniacal Salts. Sal Ammoniac.

On a volatile ſpirit or ſalt pour gradually any acid whatever. An efferveſcence will ariſe, and be more or leſs violent according to the nature of the acid. Go on adding more acid in the ſame manner, till no efferveſcence be thereby excited, or at leaſt till it be very ſmall. The liquor will now contain a ſemi-volatile neutral ſalt, called an *ammoniacal ſalt*; which may be obtained in a dry form by cryſtalliſing as uſual, or by ſubliming it in cloſe veſſels, after the ſuperfluous moiſture hath been drawn off.

Volatile alkalis have the ſame properties with fixed alkalis, fixity only excepted: ſo that a volatile alkali muſt produce an efferveſcence when mixed with acids, and form therewith neutral ſalts, differing from each other in nothing but the nature of the acid in their compoſition.

It muſt be obſerved, that the point of ſaturation is very difficult to hit on this occaſion; owing probably to the volatility of the alkali, which, being much lighter than the acid, tends always to poſſeſs the uppermoſt part of the mixture, while the acid ſinks to the bottom: whence it comes to paſs, that the lower part of the liquor is ſometimes overcharged with acid, while the upper part is ſtill very alkaline. But it is moſt eligible that the alkali ſhould predominate in the mixture; becauſe the exceſs of this principle eaſily flies off while the moiſture is evaporating in order to the cryſtalliſation or ſublimation of the ammoniacal ſalt; which being only ſemi-volatile, reſiſts the heat longer, and remains perfectly neutral.

If the vitriolic acid be combined with a volatile alkali, and the mixture diſtilled in a retort to draw off the ſuperfluous moiſture, a liquor comes over into the receiver which ſmells ſtrong of a ſulphureous acid. Now, as the acid of vitriol never becomes ſulphureous, but when it is combined with an inflammable matter, this experiment is one of thoſe which demonſtrate that volatile alkalis contain a very ſenſible quantity of inflammable matter. This ſame liquor taſtes of an ammoniacal ſalt; which proves that it carries up with it ſome of the neutral ſalt contained in the mixture. The reſt of this ſalt, which is called *Glauber's ſecret ſal ammoniac*, or *vitriolic ſal ammoniac*, ſublimes into the neck of the retort. It is very pungent on the tongue; it crackles a little when thrown on a red-hot ſhovel, and then flies off in vapours.

The ammoniacal ſalt formed by the acid of nitre exhibits much the ſame phenomena; but it requires greater care in drying and ſubliming it, becauſe it hath the property of detonating all alone, without the addition of any other inflammable matter: and it will infallibly do ſo, if too ſtrong a fire be applied towards the end of the operation, when it begins to be very dry. This property of detonating by itſelf it derives from the inflammable matter contained in the volatile alkali which ſerves for its baſis: and this is another demonſtrative proof of the exiſtence of ſuch an inflammable matter in the volatile alkali. This ſalt is called *nitrous ammoniacal ſalt*.

With the vegetable acids, that of vinegar for inſtance, is formed an ammoniacal ſalt of a ſingular nature, and which can ſcarce be brought to a dry form.

A volatile alkali, combined to the point of ſaturation with the acid of ſea-ſalt, forms another neutral ſalt, which takes a concrete form either by ſublimation or cryſtalliſation. The cryſtals of this ſalt are ſo very ſoft and fine, that a parcel of it looks like cotton or wool. This is the ſalt properly called *ſal ammoniac*. It is of great uſe in chemiſtry and in manufactures; but that which is daily conſumed in great quantities is not made in the manner above mentioned. It would come extremely dear, if we had no other way of procuring it, but by forming it thus with the acid of ſea-ſalt and a volatile alkali. This ſalt, or at leaſt the materials of which it is formed, may be found in the fuliginoſities and ſoots of moſt animal, and of ſome vegetable ſubſtances. The greateſt part of what we uſe comes from Egypt, where vaſt quantities thereof are made.

The method of preparing ſal ammoniac in Egypt was not known among us till Meſſ. Lemaire and Granger. Their memoirs inform us, that chimney-ſoot alone, without any additament, is the matter from which they obtain their ſal ammoniac; that thoſe chimneys under which nothing is burnt but cow's-dung, furniſh the beſt ſoot. Six and twenty pounds of that ſoot yield uſually ſix pounds of ſal ammoniac.

"The operation takes up about fifty, or two and fifty hours. The veſſels in which they put the ſoot are ballons of very thin glaſs, terminating in a neck of fifteen or ſixteen lines long, and an inch in diameter: but they are not all of the ſame ſize. The leaſt contain twelve pounds of ſoot, and the greateſt fifty; but they fill them only three quarters full, in order to leave room for the ſublimation of the ſalt.

"The furnace, in which they place theſe ballons, conſiſts

confifts of four walls built in a quadrangular form. The two front-walls are ten, and the fides nine foot long: but they are all five foot high, and ten inches thick. Within the quadrangle formed by thefe walls, three arches run lengthwife from end to end thereof, at the diftance of ten inches afunder. The mouth of this furnace is in the middle of one of its fronts, and of an oval form; two foot four inches high, and fixteen inches wide.

" The ballons lie in the fpaces between the arches of the furnace, which ferve inftead of a grate to fupport them. Four of them are ufually placed in each interval; which makes fixteen for one furnace. They are fet at the diftance of about half a foot from each other, and fecured in their places with brick and earth. But they leave about four inches on the upper part of the ballon uncovered, with a view to promote the fublimation, as they alfo do fix inches of the inferior part, that the heat may the better act on the matters to be fublimed. Things being thus prepared, they firft make a fire with ftraw, which they continue for an hour. Afterwards they throw in cow's-dung made up in fquare cakes like bricks. (The want of wood in this country is the reafon that they generally make ufe of this fuel.) Thefe cakes of dung add to the violence of the fire, which they continue in this manner for nineteen hours; after which they increafe it confiderably for fifteen hours more; and then they flacken it by little and little.

" When the matter contained in the veffels begins to grow hot, that is, after fix or feven hours baking, it emits a very thick and ill-fcented fmoke, which continues for fifteen hours. Four hours after that, the fal ammoniac is obferved to rife in white flowers, which adhere to the infide of the neck of the veffel; and thofe who have the direction of the operation take care from time to time to pafs an iron rod into the neck of the ballon, in order to preferve a paffage through the faline vault, for giving vent to fome blueifh vapours, which conftantly iffue out of the veffel during the whole operation."

From this hiftory of the preparation of fal ammoniac it appears, that foot, and particularly the foot of animal matters, either contains abundance of this falt perfectly formed, and waiting only for fublimation to feparate it therefrom, or at leaft that it contains the proper materials for forming it; and that during the operation, which is a kind of diftillation of foot, thefe materials combine together and fublime.

We fhewed, in our analyfis of foot, that this fubftance yields by diftillation a great deal of volatile alkali; and this is an ingredient which makes at leaft one half of fal ammoniac. As to the other principle of this falt, the marine acid, this alfo muft needs exift in foot: but it is not fo eafy to conceive how it fhould come there.

It is very true that vegetable and animal fubftances, the only ones that produce foot in burning, contain fome portion of fea-falt: but then this falt is very fixed, and feems unfit to rife with the acid, the oil, and the fubtile earth, of which the volatile alkali is formed. Therefore we muft fuppofe either that its elevation is procured by the force of the fire, aided by the volatility of the matters that exhale in burning; or that, being decompofed by the violence of the combuftion, its acid alone rifes with the other principles above mentioned. The latter feems probable enough: for though in the common operations of chemiftry the bare force of fire doth not feem fufficient to decompofe fea-falt; yet the example of fea-plants, which, before burning, contain this falt in abundance, and whofe afhes contain fcarce any at all, but are replete with its fixed part, that is, with its alkaline bafis, feems to prove, that, when this falt is intimately mixed with inflammable matters, it may be deftroyed by burning; fo that its acid fhall defert its bafis, and fly off with the foot.

Before the exact method of procuring fal ammoniac was known, it was generally imagined that the manufacturers mixed fea-falt, and even urine, with the foot; becaufe thefe two fubftances contain the principles of which this falt confifts. But, befides that the contrary now certainly appears from the above mentioned memoirs, it hath been fhewn by Mr Duhamel, who hath publifhed feveral memoirs and experiments concerning the compofition and decompofition of fal ammoniac, from which we have partly taken what we have already faid on this fubject; it hath been fhewn, in the firft of thefe memoirs, that the addition of fea-falt to the foot, from which fal ammoniac is to be extracted, contributes nothing to its production, and cannot increafe its quantity. That alone, therefore, which was originally contained in the matters that produced the foot, enters as a principle into the compofition of fal ammoniac.

Sal ammoniac is fometimes found perfectly formed in the neighbourhood of vulcanos. This falt is probably produced from the fuliginofities of vegetable or animal matters confumed by the fire of the vulcano.

Sal ammoniac is often impure, becaufe it carries up with it, in fublimation, fome of the black charred matter which ought to be left at the bottom of the veffel: but it is eafily purified. For this purpofe you need only diffolve it in water, filter the folution, then evaporate and cryftallize; by which means you will have a very white and very pure fal ammoniac. You may if you pleafe, fublime it again in a cucurbit and blind head, with a fire not too brifk. Some of it will rife in the form of a light white powder, called *flowers of fal ammoniac*. Thefe flowers are no other than true fal ammoniac, which hath fuffered no decompofition; becaufe the bare action of fire is not capable of feparating the acid and the volatile alkali, of which this neutral falt confifts. When you intend to decompofe it, you muft ufe the means to be mentioned hereafter.

Though fal Ammoniac be only femi-volatile, and requires a confiderable heat to fublime it, yet it hath the property of carrying up with it matters that are veryfixed and ponderous; fuch as metallic fubftances, and fome kinds of earths. For medicinal ufes we fublime therewith iron, lapis hæmatites, the copper in blue vitriol, &c. and then it takes different names, as *martial flowers of fal ammoniac*, *ens veneris*, and other fuch denominations, which it borrows from the matters fublimed with it.

Sal Ammoniac decompounded by acids.

INTO a large tubulated retort put a ſmall quantity of ſal ammoniac in powder: ſet your retort in a furnace, and lute on a large ballon, as in the diſtillation of the ſmoking acids of nitre and ſea-ſalt. Through the hole in your retort pour a quantity of oil of vitriol or ſpirit of nitre equal in weight to your ſal ammoniac. An effervеſcence will inſtantly follow. The mixture will ſwell, and diſcharge white vapours which will come over into the receiver. Stop the whole in the retort immediately, and let the firſt vapours paſs over, together with ſome drops of liquor, which will diſtil without fire. Then put a few coals into the furnace, and continue the diſtillation with a very gentle heat; which however muſt be increaſed little by little till nothing more will come over. When the operation is finiſhed, you will find in the receiver a ſpirit of ſalt if you made uſe of oil of vitriol; or an *aqua regis*, if the ſpirit of nitre was employed: and in the retort will be left a ſaline maſs, which will be either a glauber's ſecret ſal ammoniac, or a nitrous ſal ammoniac, according to the nature of the acid uſed to decompound the ſal ammoniac.

Sal ammoniac decompounded by fixed Alkalis. Volatile ſalt. The Febrifuge of Sylvius.

INTO a glaſs alembic or retort put ſal ammoniac and ſalt of tartar pulveriſed and mixed together in equal quantities. Set your veſſel in a proper furnace, and immediately lute on a large receiver. A little volatile ſpirit will aſcend; and a volatile alkali, in a concrete form, very white and beautiful, will ſublime into the head, and come over into the receiver, in quantity near two thirds or three fourths of the ſal ammoniac uſed. Continue the diſtillation, increaſing the fire by degrees till nothing more will ſublime. Then unlute the veſſels. Put up your volatile ſalt immediately into a wide mouthed bottle, and ſtop it cloſe with a cryſtal ſtopple. At the bottom of the retort or cucurbit you will find a ſaline maſs, which, being diſſolved and cryſtalliſed, will form a ſalt nearly cubical, having the taſte and other properties of ſea-ſalt. This is the *ſal febrifugum ſilvii*.

Sal Ammoniac decompounded by abſorbent Earths and Lime. Fixed Sal Ammoniac.

LET one part of ſal ammoniac and three parts of lime ſlaked in the air be pulveriſed ſeparately, and expeditiouſly mixed together. Put this mixture immediately into a glaſs retort, ſo large that half of it may remain empty. Apply thereto a capacious receiver, with a ſmall hole in it to give vent to the vapours, if needful. Let your retort ſtand in the furnace about a quarter of an hour, without any fire under it. While it ſtands thus, a great quantity of inviſible vapours will riſe, condenſe into drops, and form liquor in the receiver. Then put two or three live coals in your furnace, and gradually increaſe the fire till no more liquor will riſe. Now unlute your veſſels, taking all poſſible care to avoid the vapours, and quickly pour the liquor out of the receiver into a bottle, which you muſt ſtop with a cryſtal ſtopple, rubbed with emery. There will remain, at the bottom of the retort, a white maſs, conſiſting of the lime employed in the diſtillation, together wit the acid of the ſal ammoniac: this is called *fixed ſal ammoniac*.

Volatile Alkalis combined with oily matters. A Volatile Oily Aromatic ſalt.

PULVERISE and mix together equal parts of ſal ammoniac and ſalt of tartar: put the mixture into a glaſs or ſtone cucurbit: pour on it good ſpirit of wine till it riſe half an inch above the matter. Mix the whole with a wooden ſpatula; apply a head and a receiver, and diſtil in a ſand-bath, gently heated, for two or three hours. A volatile ſalt will riſe into the head; and then the ſpirit of wine will diſtil into the receiver, carrying with it a portion of the volatile ſalt.

When nothing more will come over, let your veſſels cool; then unlute them, ſeparate the volatile ſalt, and weigh it directly. Return it into a glaſs cucurbit, and for every ounce thereof add a dram and a half of eſſential oil, drawn from one or more ſorts of aromatic plants. Stir the whole with a wooden ſpatula, that the eſſence may incorporate thoroughly with the volatile ſalt. Cover the cucurbit with a head, fit on a receiver, and, having luted it exactly, diſtil in a ſand-bath, as before, with a very gentle heat. All the volatile ſalt will riſe, and ſtick to the head. Let the fire go out, and when the veſſels are cooled take your ſalt out of the head. It will have an odour compounded of its own proper ſmell, and the ſmell of the eſſence with which it is combined. This is an *aromatic oily ſalt*. Put it into a bottle ſtopped cloſe with a cryſtal ſtopple.

A TABLE, Shewing the manner in which natural bodies, conſidered in a chemical view, may be divided into claſſes: With their ſeveral ſubdiviſions; their properties defined; and the manner in which they are obtained, pointed out.

NATURAL BODIES, conſidered as the objects of CHEMISTRY, may be divided into the ſix following claſſes, *viz.*

1. SALINE. Theſe are ſoluble in water, ſapid, and not inflammable. They are either
   - SIMPLE, are thoſe which can be no further analized by chemiſtry; and are of two ſorts, *viz.*
     - ACIDS. Theſe are diſtinguiſhed by turning ſyrup of violets red, and forming with alkalis neutral ſalts. The different acids yet known are theſe.
       - *Vitriolic.*
         - *Fixed.* The moſt ponderous of all fluids next to mercury, and the moſt fixed in the fire, and moſt powerful as a ſolvent of all the acids. Obtained chiefly from ſulphur by inflammation.
         - *Volatile.* Obtained alſo from ſulphur by inflammation, air being admitted during the operation. This acts leſs powerfully as a ſolvent than when in its fixt ſtate.
       - *Nitrous,* or *Aquafortis.* A volatile fluid of a reddiſh colour, emitting noxious fumes when in its concentrated ſtate. The next acid in ſtrength to the vitriolic. Obtained chiefly from nitre.
       - *Muriatic,* or *acid of ſea-ſalt.* A volatile fluid of a beautiful yellow colour. Inferior in power to the former. Obtained from ſea-ſalt.
       - *Vegetable.*
         - *Native.* This is obtained by expreſſion or diſtillation from vegetables; as lemon-juice, citron, ſorrel, &c.
         - *Fermented.*
           - *Tartar.* A dry hard ſubſtance, depoſited on the ſides of veſſels in which wine is fermented.
           - *Vinegar.* By allowing any fermentable liquor to proceed in the fermentation till it is paſt the vinous ſtate. All theſe vegetable acids are much leſs corroſive, and leſs powerful as ſolvents, than any of the former.
       - *Acid of urine.* Obtained by evaporating urine. This is in a dry form; and much leſs known in arts than the former.
       - *Acid of amber.* Obtained from amber in a ſolid form. This is likewiſe little known in arts.
       - *Acid of ants.* Obtained from the animal from which it has its name, by diſtillation, in a fluid form. It is alſo little known.
       - *Acid of borax,* or *ſedative ſalt.* Obtained from borax, in a ſolid ſtate and ſcaly-like form.
       - *Acid of arſenic.* Obtained likewiſe from arſenic.
       - *Acid of animals.* Obtained from all animal-ſubſtances in diſtillation.
     - ALKALIS, turn ſyrup of violets green, and with acids form neutrals; and are divided into
       - *Fixt*
         - *Vegetable,* or *potaſh.* Always obtained from the aſhes of burnt vegetables. A deliqueſcent ſalt.
         - *Foſſile.* A ſolid cryſtalline ſalt; ſometimes found native, as the natrum of Egypt; and ſometimes by burning ſea-weed, as kelp.
       - *Volatile.* This is obtained from ſal ammoniac, from the ſoot of burning bodies, and from the putrefactive fermentation. It is naturally in a ſolid ſtate.
   - COMPOUND, conſiſting of two or more chemical elements. Divided into
     - *Neutral ſalts.* Theſe are always compoſed of an acid and an alkali; and are of many different kinds, as may be ſeen in the following table.
     - *Metallic ſalts,* are thoſe which are formed by an acid and a metal. The principal of theſe are vitriols; the others may be ſeen in the following table.
     - *Earthy ſalts.* Compoſed of an acid joined to ſome earthy baſis, as in allum and gypſum. See the following table.
     - *Eſſential ſalts,* are obtained from vegetables; and contain an acid, joined with the juices of the plant in a particular manner not to be imitated by art. Of this kind is ſugar, manna, honey, and others of that ſort.
2. INFLAMMABLES, are thoſe bodies that continue to burn of themſelves if they are once ſet on fire. Divided into
   - OILS, are thickiſh viſcous fluids, not miſcible with water. Divided into
     - *Animal, Vegetable,* both of which are divided into
       - *Expreſſed.* Theſe are of a mild and bland taſte, inodorous, and not ſoluble in alcohol. They are obtained by expreſſion; as, oil of olives, rapſeed, almonds, &c. Animal-fats are of the ſame nature, as is alſo wax.
       - *Eſſential,* are always obtained by diſtillation, and are poſſeſſed of the taſte and odor of the ſubſtance from which they are drawn, and are ſoluble in alcohol. Of this kind are oil of cloves, ſpike, &c. The oil of ants is an example in the animal-kingdom.
       - *Empyreumatic,* are obtained by a conſiderable degree of heat; and are of an acrid taſte and burnt-like flavour, as oil of hartſhorn. Theſe are ſoluble in ſpirit of wine.
     - *Foſſile.* Theſe are found in the earth in their native ſtate; and are called, when pure, *naptha;* which is of an acrid taſte, and extremely volatile; not miſcible with alcohol. A great many inflammable foſſils contain this; as, bitumens, pit-coal, &c.
   - SULPHUR, or *brimſtone.* A dry friable ſubſtance, not miſcible with water. It is found in many mineral ſubſtances, metallic ores, &c.; but it is for the moſt part obtained from pyrites.
   - ALCOHOL, or *ardent ſpirits.* A fluid of an acrid and volatile nature, miſcible with water. Obtained from fermented vegetable juices by diſtillation; as, from the juice of the grape, malt-liquors, rice, &c.
3. METALLIC, are bodies of a hard and ſolid texture, fuſible in the fire, and reſuming their proper form after that; not miſcible with water, nor inflammable. Divided into
   - METALS. Theſe are malleable. Divided into
     - *Gold.* The moſt ponderous and ductile, and the moſt fixed in the fire, of all bodies; of a yellow colour. It is more commonly found in its metallic ſtate than any other metal. There is no proper ore of it: But it is found in ores of ſilver; and almoſt all ſands contain ſome of it.
     - *Silver.* It is of a ſhining white colour, and next to gold in weight, malleability, and fixity. Sometimes found in its native ſtate; more frequently in that of an ore, with ſulphur, ſometimes arſenic; aſſuming different appearances.
     - *Lead.* Of a dull bluiſh colour, exceeding ſoft, and eaſily malleable, and next to the foregoing metals in weight. Almoſt never found in its metallic ſtate; uſually in an ore with ſulphur or arſenic, but ſeldom with ſulphur alone. The principal ores of it are the cubic, called *galena,* and the glaſſy called *ſparr.*
     - *Copper.* Of a reddiſh colour; hard and ſonorous; admits of being extended greatly under the hammer, either hot or cold. It is difficult of fuſion. This is generally found in the ſtate of an ore with ſulphur. The ores of it are of great variety, and extremely beautiful; blue, red, green, yellow, &c.
     - *Tin.* A white ſoft metal, the lighteſt of all this claſs, and very ductile. The ores of this metal are generally arſenical, and aſſume a cryſtalline appearance. The colour moſt uſually a dark brown, and ſometimes very beautiful.
     - *Iron.* A grey-coloured metal, extremely ductile when hot; the lighteſt metal except tin. It is the only metal that admits of being welded, and tempered by cooling. It is found in almoſt every body, and its ores are infinitely various.
   - SEMI-METALS, are brittle, and do not ſtretch under the hammer; and are,
     - *Mercury.* A white opaque metallic body. Fluid, except in a very intenſe degree of cold; of great gravity, and eaſily volatilized in heat. It is ſometimes found in its fluid form; but uſually in a beautiful red ore with ſulphur, called *cinnabar.*
     - *Zinc.* A bluiſh white ſubſtance, of a fibrous texture, conſiderably hard and ſonorous, and has a ſmall degree of ductility; eaſily fuſed and volatilized. Lapis calaminaris is its principal ore.
     - *Antimony.* A blackiſh ſubſtance, of a fibrous needle-like texture; hard and brittle, and conſiderably heavy; not difficult of fuſion, and eaſily converted into glaſs. Its only ore is with ſulphur, which is the crude antimony of the ſhops.
     - *Biſmuth,* or tin-glaſs. A white, ponderous, hard, brittle, and ſonorous body, of a plated texture; eaſily fuſed and vitrified. It is only reduced to an ore by arſenic. Its appearance much the ſame as the regulus.
     - *Arſenic.* A bright ſparkling whitiſh-coloured ſemi-metal; of a plated texture, very brittle, and extremely volatile. It is generally found in the ores of other metals.
     - *Platina.* A white ſemi-metal, reſembling ſilver in its colour; nearly of the ſame ſpecific gravity and fixity with gold, and reſiſting the teſts which have uſually been applied for diſcovering the purity of gold, ſuppoſed from hence to be the *ſmiris* of the ancients. Found in the Weſt Indies. Of its ores we know nothing.
     - *Cobalt.* A brittle ſemi-metal; fuſible in a moderate heat, and eaſily converted into a fine blue-coloured glaſs called *ſmalt.* This is always obtained from an arſenical ore, which is likewiſe called *cobalt.*
     - *Nickel.* A reddiſh white ſubſtance, of a cloſe texture, and very bright; eaſily fuſed, but difficult to vitrify. Of its ores we know nothing.
4. EARTHY. Theſe are ſolid bodies; not ſoluble in water; not inflammable; and, if fuſed in the fire, never again reſume their earthy form, but take that of glaſs. Divided into
   - ABSORBENT. Theſe are capable of being united with acids; and are either
     - *Calcarious.* Thoſe that can be converted into quick-lime.
       - *Lime-ſtone,* or *marble.* This is of infinite variety of colours and texture. Marble is the hardeſt and fineſt. Thoſe kinds of lime-ſtone which feel unctuous to the touch are generally impregnated with clay; thoſe that feel gritty, or where the lime is hard and weighty, contain ſand: This is beſt for building, the other for manure.
       - *Chalk.* A ſoft, friable, white ſubſtance. This is much freer of any heterogeneous mixture than any lime-ſtone, and is eaſily calcined into quick-lime. This is probably nothing elſe than lime-ſtone ſuddenly concreted without being cryſtallized.
       - *Sea-ſhells,* are likewiſe a calcarious earth, and yield a very fine quick-lime. Theſe are uſed in medicine.
     - *Not calcarious.*
       - *Magneſia alba.* A white earth, uſually found combined with the vitriolic acid, and forming bitter purging ſalt. It is likewiſe obtained from the mother-lye of nitre, the aſhes of burnt vegetables, &c.
       - *Earth of allum.* A particular kind of abſorbent earth, found in many places mixed with ſulphureous pyrites, as in Yorkſhire, &c. Clay of any kind may, by a particular proceſs, be converted into this earth.
       - *Earth of animals,* &c. This is obtained by the calcination of animal-ſubſtances. It can hardly be converted into glaſs; and is therefore uſed as a baſis to white enamels, &c.
   - CRYSTALLINE, or *Vitreſcent.* Theſe are hard, and ſtrike fire with ſteel; may be calcined in the fire; but are not ſoluble in acids.
     - Of this kind are *ſand, flint,* &c. found plentifully every where. With alkaline ſubſtances they are eaſily converted into glaſs, and hence are termed *vitreſcent.*
     - *Precious ſtones* of all kinds are likewiſe referable to this claſs; but they are of a much greater degree of hardneſs and tranſparency than the others.
   - ARGILLACEOUS. Theſe are diſtinguiſhed by acquiring a very hard conſiſtence when formed into a paſte with water, and expoſed to a conſiderable degree of heat; not ſoluble in acids.
     - *Common clay;* is of many different colours, but chiefly red or yellow or white. The pureſt clay is that which burns white in the fire.
     - *Medical boles,* of different ſorts. Only a purer kind of clay; ſometimes mixed with a little iron or other matters.
     - *Lapis nephriticus,* or ſteatite, are indurated clays, found in various parts. Theſe are at firſt ſoft, and readily cut; but turn extremely hard in the air. Many other varieties of theſe earths might be mentioned; but as theſe do not differ in their chemical properties ſo much as in their external appearance, and being all mixed with one another, they more properly belong to the natural hiſtorian than the chemiſt.
5. WATER, a colourleſs inſipid fluid well known.
   - SIMPLE. *Pure rain-water.* This is never perfectly pure, but always contains a ſmall portion of mucilaginous matter, which it is impoſſible ever to get perfectly ſeparated.
   - MINERAL, are thoſe ſpring-waters impregnated with ſaline ſubſtances; the diverſity of which is exceeding great; but they all agree in having an acid joined with them. The moſt common ſorts are impregnated with ſulphur and iron.
6. AIR.
   - ELASTIC. This is a ſubtile elaſtic fluid, every where ſurrounding this earth, and forming our atmoſphere; and in this ſtate may be conſidered as a menſtruum for water and other volatile bodies; but as it only ſuſpends them, without altering their qualities, it cannot properly, in this ſtate, be conſidered as an object of chemiſtry.
   - FIXT. This is a fluid, ſuppoſed to be common air, which is abſorbed by bodies, and there fixed; forming with them a true chemical mixt, differing in its properties from what it was without it. The bodies whoſe qualities we certainly know to be altered by this, are alkalis and quick-lime; and it is demonſtratively preſent in metals; And it is probably owing to it that they retain their metallic form; but experiments are yet wanting here.

A TABLE. Shewing the several combinations that the SIMPLE CHEMICAL ELEMENTARY BODIES admit of with one another; the compound resulting from that mixture; and the manner in which the union is effected: With some account of the principal uses to which these are applied in arts or manufactures.

N. B. This mark *, put above any word, denotes that there is some difficulty in the process, or that the union is not very complete.

The VITRIOLIC ACID may be combined with these bodies, viz.

- ACIDS.
  - NITROUS ACID. A mixture which readily inflames oils. By solution, generating heat.
  - MURIATIC, VEGETABLE, and all other ACIDS yet known. By solution, generating heat. But these mixtures are applied to no particular use in medicine or arts.
- ALKALIS.
  - VEGETABLE.
    - *Vitriolated tartar.* By solution and crystallization, or double elective attraction from a great variety of bodies.
    - *Nitrum vitriolatum.* A vitriolated tartar obtained by distilling from nitre with the vitriolic acid.
    - *Sal polychrestum.* By deflagrating nitre with sulphur. There are many other kinds of vitriolated tartar, known formerly by different names, and supposed to be possessed of particular properties, but they are now neglected.
  - FOSSILE. *Glauber's salt.* By solution and crystallization. Much used in medicine as a gentle purgative.
  - VOLATILE. *Secret ammoniac.* By solution. Formerly supposed a most powerful menstruum for metals, *&c.* but without any just foundation.
- OILS.
  - EXPRESSED. A blackish gummy-like mass. By solution, generating a considerable heat. Native gums are supposed to owe their origin to a mixture of this kind.
  - ESSENTIAL. A dark-coloured resinous mass. A great heat and violent effervescence being produced by this mixture. Native resins supposed the same.
  - EMPYREUMATIC. Little known. By solution.
  - FOSSILE. A substance resembling amber. By solution.
- SULPHUR *. Here there is no proper union of substances; but if sulphur is boiled in this acid, it becomes less inflammable and more fixed than any ordinary sulphur.
- ALCOHOL.
  - *Vitriolic æther.* By careful solution and distillation, the æther being separated by the addition of water.
  - *Spiritus vitrioli dulcis.* By solution and distillation.
  - *Oleum destillatio dulcis.* By continuing the heat after the æther has arisen.
  - *Oleum anodynum minerale.* By redistilling the residuum of the last with alcohol. A medicine much celebrated by Hoffman.
  - *Sulphur.* By pushing the heat after the oil comes over. It is to be observed that this is produced in every combination of this acid with inflammables or metals.
- METALS.
  - GOLD *. Imperfectly. By a particular process after being separated from aqua regia.
  - SILVER *. By solution, after it has been precipitated from the nitrous acid by alkalis. The fumes which arise in this solution are inflammable.
  - COPPER. *Blue vitriol.* This is sometimes a native production, but in this way it is never pure. It is artificially prepared by solution in a very concentrated acid, and crystallizing it.
  - IRON.
    - *Green vitriol*, or *copperas.* Obtained at large by a particular process from pyrites; or by solution, *&c.* in a diluted acid. This is the basis of all black dyes, ink, *&c.* as it strikes a black colour with vegetable astringents.
    - *Salt of steel.* By calcining the crystals of green vitriol till they are converted into a white powder.
    - *Colcothar of vitriol.* By continuing the calcination till it assumes a brown colour.
  - LEAD.
    - *Saturnus vitriolicus.* A solution in a boiling heat, but is again precipitated when cold.
    - An indissoluble concrete. By precipitation from the nitrous acid.
  - TIN. *Jupiter corrosivus.* By a boiling heat in a concentrated acid.
- SEMI-METALS.
  - ANTIMONY *. *A metallic salt.* By elective attraction from butter of antimony.
  - ZINC. *White vitriol.* Often found in its native state. Artificially made by solution and crystallization in a diluted acid. Used by painters for drying.
  - BISMUTH. A corroded calx. By solution in a concentrated acid.
  - ARSENIC. - - - By ditto.
  - MERCURY.
    - *Ignis Gehenne*, or infernalis of Paracelsus. By a boiling heat, and repeated coctions with fresh acid when it is evaporated.
    - *Turpeth mineral*, or mercurius precipitatus flavus. By evaporating to driness, and then washing with water.
  - COBALT. A rose-coloured mixture. By solution. If this is precipitated by a fixt alkali, and again dissolved, the liquor appears of a beautiful red.
- EARTHS.
  - CALCARIOUS EARTHS.
    - A corroded calx. By simple corrosion. This when perfectly edulcorated with water is found to be a true gypsum.
    - *Selenites.* By precipitation from a very dilute solution of chalk in the nitrous acid, by means of the vitriolic acid.
    - *Gypsum*, or *Paris-plaster.* Often found in a native state. May be artificially formed by precipitating from a solution of chalk in a very concentrated nitrous acid. Used as a cement; for taking impressions from medals, *&c.*
    - *Talc, asbestos, &c.* A native production which cannot be perfectly imitated by art. Used for holding objects in microscopes, making incombustible cloth, *&c.*
  - MAGNESIA. *Epsom*, or *magnesia Glauber's salt.* By solution and crystallization. Much used in medicine for the same purposes as real Glauber's salt.
  - EARTH of ALUM. *Alum.* By solution, crystallization, *&c.* Used by dyers as a preparatory for taking on the colours, papermakers, goldsmiths, *&c.*
  - EARTH of ANIMALS, OSTEOCOLLO, *&c.* By solution. The mixtures of these are not applied to any particular use.
  - CLAY *. *Alum.* By digesting pure clay for some time in this acid, and exposing it for some time to the air, an alum is produced; and, if the clay is precipitated from this aluminous concrete, it is found to be a pure earth of alum, soluble in all acids.
  - FLINT *. A thickish coagulum. By digesting the liquor silices in the vitriolic acid.
- WATER. An acidulated water. Sometimes, though seldom, found issuing along with native springs. Applied to no particular use.

NITROUS ACID.

- ACIDS.
  - VITRIOLIC, as above.
  - MURIATIC. *Aqua regia.* By solution. This is the only proper menstruum for gold; and it is a solution of tin in this menstruum which is the basis of the scarlet dye.
  - VEGETABLE, and all others. By ditto. These compounds have no particular names, nor are applied to any particular uses in medicine or arts.
- ALKALIS.
  - VEGETABLE. *Common nitre.* A native production. Made artificially by solution and crystallization. This deflagrates with oily or metallic bodies, and is the foundation of gun-powder.
  - FOSSILE. *Cubic nitre.* By solution.
  - VOLATILE. *Nitrous ammoniac.* By solution. This differs from all the other ammoniacal salts by being soluble in alcohol.
- OILS.
  - EXPRESSED. A thick bituminous-like substance. Upon the mixture a considerable degree of heat is generated, and sometimes, though very seldom, actual flame is produced.
  - ESSENTIAL. Ditto. A more violent heat is generated upon the mixture with these oils than any other, and with many of them an actual flame is produced.
  - EMPYREUMATIC. This mixture has no name, nor is it applied to any remarkable use in arts.
  - FOSSILE. - - Ditto.
- ALCOHOL.
  - *Nitrous æther.* By digesting; the æther arising to the surface.
  - *Spiritus nitri dulcis.* By digesting a little, and then distilling.
- METALS.
  - GOLD *. *Slightly impregnated.* By a boiling heat in close vessels, after the ordinary method of separating silver from gold by the nitrous acid. It spontaneously subsides in the air.
  - SILVER.
    - *A fluid solution.* By solution. This when diluted with water stains hair and bones black; as also marble, agate, jasper, *&c.* of different colours.
    - *Sal metallorum.* By solution and crystallization.
    - *Catharticum lunare, lunar caustic*, or *lapis infernalis.* By inspissitating the solution to driness.
  - COPPER. A green-coloured solution. By solution.
  - IRON. A greenish solution, if a diluted acid is employed; if otherwise, it is of a yellowish colour: evaporated to driness, it deliquates in the air.
  - LEAD.
    - A yellow solution. By dissolving in a diluted acid. If much water is added, the metal is precipitated.
    - *Saturni fulminans.* By inspissating the solution. This explodes when put upon the fire with greater force than nitre, and has been proposed to be used as an ingredient in gun-powder to augment its force.
  - TIN. A solution or corroded calx. By a careful solution without heat it remains suspended; if otherwise, it falls down in form of a calx. This is commonly supposed to be the composition used in dying scarlet; but by mistake: for it is a solution of tin in aqua regia that communicates that fine colour to cochineal. The same solution is the basis of the powder which tinges glass of a ruby colour. It is the precipitate of gold from aqua regia by means of tin.
- SEMI-METALS.
  - BISMUTH.
    - A greenish solution. By using a concentrated acid. This might be applied in some cases in the art of dying; but is not yet come into general use.
    - *Magistery of bismuth.* By precipitating from the solution by means of water. This has been employed as a cosmetic, but is inefficacious and unsafe. If mixed with pometum, this stains hair of a dark colour without injuring it.
  - MERCURY.
    - A limpid solution, intensely corrosive. By solution.
    - *Red precipitate.* By evaporating the solution to driness, and then calcining till it becomes red.
    - *Mercurius corrosivus fusus.* By precipitating from the nitrous acid by fixt alkali.
    - *White precipitate.* - By ditto with the volatile alkali.
  - ZINC. A corroded solution. By the ordinary means.
  - ANTIMONY.
    - A colourless calx. By simple corrosion.
    - *Bezoardic mineral.* By distilling from butter of antimony, after having added the nitrous acid.
    - *Antimonium diaphoreticum.* By adding nitre to crude antimony, and deflagrating.
    - *Cerusa antimonii.* By deflagrating regulus of antimony with nitre.
  - COBALT.
    - A red liquor. By solution either in its calcined or metallic state.
    - *Rose-coloured crystals.* By adding muriatic acid, and allowing it to crystallize.
    - *Green sympathetic ink.* By dissolving these crystals in water. The solution is red when cold, and green when warm: when wrote with, it disappears when dry; but when held to the fire it becomes green, and again disappears when cold.
  - NICKEL. A green-coloured liquor. By solution.
- EARTHS.
  - CALCARIOUS.
    - *Deliquescent crystals.* - By ditto and crystallization.
    - *Baldwin's phosphorus.* By ditto and evaporating to driness.
  - EARTH of ALUM, and all other absorbent earths. By solution. The compounds have no names nor any remarkable properties hitherto discovered.
  - CRYSTALLINE EARTHS *. By solution after precipitation from the liquor silices.
- WATER. *Acidulated water.* By solution.

- ACIDS.
  - VITRIOLIC, and NITROUS. As in the former part of this table.
  - VEGETABLE, and all others yet known. By solution: but as none of these mixtures are applied to any particular purpose, we take no notice of them.
- ALKALIS.
  - VEGETABLE. *Digestive salt.* By solution and crystallization.
  - FOSSILE.
    - *Common salt.* Commonly obtained by evaporating sea-water to driness; or artificially made by mixing the acid and alkali, and crystallizing.
    - *Sal gem.* A native fossile salt, found in mines in Poland, Spain, *&c.* of the same nature as common salt, but more pure.
  - VOLATILE. *Common ammoniac.* Obtained at large by a particular process from soot. Artificially made by mixing the acid and alkali, and crystallizing.
- OILS *. By solution. The union here is but imperfect, nor have they any particular name.
- ALCOHOL. *Spiritus salis dulcis.* By digesting, and afterwards distilling. The acid here is never totally dulcified.
- METALS.
  - GOLD *. *A yellow liquor.* By boiling a calx of gold (in whatever way obtained) in this acid. It does not act upon it in its metallic state.
  - SILVER *.
    - *A fluid solution.* By dissolving the ore of silver in this acid. It does not act upon pure metallic silver.
    - *Luna cornea.* By elective attraction from the nitrous acid.
  - COPPER. *A green deliquescent inflammable salt.* By solution and inspissating to driness.
  - IRON. *Tinctura martis aurea.* By solution. The iron is in some measure rendered volatile by this operation.
  - LEAD.
    - A limpid solution. By a boiling heat, and frequent cohobations with fresh acid.
    - *Cornea Saturni.* By precipitation from the nitrous acid.
  - TIN *.
    - A corroded powder. By simple corrosion.
    - *Butter of tin.* By distilling from corrosive sublimate.

The MURI... ned with these bodies, viz.

ZINC. A solution of a very slight yellow colour. ... By employing a very concentrated acid.

The MURIATIC ACID can be combined with these bodies, *viz.*

- TIN *. { A corrod[...]
  - *Butter of tin.* By distilling from corrosive sublimate.
- MERCURY *. A colourless crystalline mass, extremely acrid. By corrosion, employing the fumes of a very concentrated acid.
- SEMI-METALS.
  - BISMUTH *. A solution very slightly impregnated. By employing a very concentrated acid.
  - ZINC. A solution of a very slight yellow colour.
  - ARSENIC *. *Butter of arsenic.* By distilling corrosive sublimate with arsenic; the arsenic uniting with the acid, and leaving the mercury.
  - MERCURY *.
    - *Mercur. corrosiv. albus.* By precipitation from the nitrous acid.
    - *Corrosive sublimate.* By subliming from sal ammoniac, common salt, or many other bodies.
    - *Mercurius dulcis.* By resubliming corrosive sublimate with more quicksilver.
    - *Mercurial panacea.* By subliming corr. sub. nine times, and digesting for some time in spirit of wine.
  - COBALT. A reddish solution. By the ordinary means. It becomes green by a gentle heat.
  - PLATINA *. A fluid solution. With difficulty effected, after having been precipitated from aqua regia by alkalis.
  - NICKEL. A green solution. By the ordinary means.
- EARTHY.
  - CALCARIOUS.
    - *Liquid shell.* By solution. A substance whose effects in medicine have been greatly extolled.
    - *Ol. calcis per deliquium.* By evaporating liquid shell to driness. It naturally deliquesces.
    - *Fixt ammoniac.* By solution and crystallization. This sometimes appears luminous in the dark when struck with a hammer.
  - OSTEOCELLO, MAGNESIA, and other absorbents. By solution; but the properties or uses of these are not known.
- WATER. *Acidulated water.* Generating heat by mixture.

VINEGAR, or VEGETABLE ACID can be combined with these bodies, *viz.*

- ACIDS. VITRIOLIC, NITROUS, and MURIATIC, as in the above table. It likewise unites with all other acids, generating heat; but the properties or uses of these are not known.
- ALKALIS.
  - VEGETABLE. *Regenerated tartar.* By solution and crystallization.
  - FOSSILE. *Polychrest of Rochelle.* By ditto.
  - VOLATILE. *Spiritus mendereri.* By solution.
- OILS *. The union here is imperfect, nor have any of them obtained particular names.
- ALCOHOL. A mixture much used for anointing sprains, &c.
- METALS.
  - SILVER *. *Lunar caustic.* By dissolving in this acid a precipitate of silver from the vitriolic acid by means of fixt alkali, and evaporating the solution to driness.
  - COPPER. *Verdegris.* By solution and crystallization; or at large, by stratifying copper plates with the husks of the grape.
  - IRON. *Sal martis aperiens.* By solution and crystallization.
  - LEAD.
    - *Ceruse.* By exposing, in certain circumstances, thin plates of lead to the fumes of vinegar.
    - *Saccharum Saturni.* By solution and crystallization.
  - TIN *. This is not properly dissolved; but the acid is evidently impregnated. By the ordinary means of solution.
- SEMI-METALS.
  - ZINC. A colourless solution of a sweetish taste. By digesting for some time.
  - MERCURY *.
    - *A fluid solution.* By employing a precipitate of mercury from the nitrous acid by alkalis.
    - *A red calx.* By long digestion with fluid mercury.
  - ANTIMONY *. *Vinum benedictum.* This is not a proper solution of the metal, but the acid is impregnated with an emetic quality.
  - ARSENIC. *Vinum arsenicum.* By ditto.
  - BISMUTH. An austere stiptic liquor. By strong coction.
- EARTHY.
  - CALCARIOUS EARTHS. *Earthy salts.* Not known in medicine or arts.
  - MAGNESIA. *Dr Black's purging salt.* By solution. It unites with all the other absorbent earths; but the properties of these mixts are unknown.
- WATER. *Acidulated water.*

ACID of URINE.

- ACIDS of all kinds. The nature of these not known.
- ALKALI. VOLATILE. A glass-like saline substance called *microcosmic salt.* The acid is always found in this state by evaporating urine.
- OILS. *Baldwin's phosphorus.* By distilling with substances that contain oils or inflammable matters.
- METALS.
  - LEAD. An inflammable malleable mass. By calcining the dry salt with lead.
  - TIN. A mass resembling zinc; and inflammable. By ditto.
  - IRON.
    - A true *phosphorus.* By ditto.
    - A bluish solution. By employing a watery solution of the acid.
  - COPPER. A corroded powder, or green solution. By a boiling heat in a watery solution of the acid.
- SEMI-METALS.
  - MERCURY. A semi-opaque mass. By fusion with the acid in its solid form.
  - ZINC.
    - A corroded powder, soluble in water. By solution in the acid in a watery situation.
    - A true *phosphorus.* By fusion with the dry acid.
  - ANTIMONY.
    - A solution in the ordinary way.
    - A brilliant striated mass. By fusion with the dry acid.
  - BISMUTH. A mixture but little changed in appearance from ordinary bismuth. By fusion.
  - ARSENIC. A whitish semi-transparent deliquescent mass. By fusion.
  - COBALT. A reddish tincture. By solution.
- VITRESCENT EARTHS. Glass of different sorts. By fusion.

ACID of AMBER.

- ALKALI.
  - FIXED. A neutral saline mass which would not crystallize. By solution.
  - VOLATILE.
    - A neutral ammoniacal oleaginous liquor, extremely volatile. By solution with a pure alkali.
    - *Liquor cornu cervi succinatus.* By solution, using salt of hartshorn.
- OIL. FOSSILE. *Amber.* A native production; but may be again artificially formed by uniting these together by solution.
- METALS.
  - COPPER. It dissolves very slowly in its metallic state; but corrodes it much more readily when calcined.
  - IRON. Dissolves a part into a colourless liquor, but corrodes a great deal more into a crocus.
- SEMI-METAL. ZINC. A fluid solution.
- The effects of this acid upon other bodies are not yet known.

ACID of ANTS.

- ACIDS of all kinds. The properties not known.
- ALKALIS.
  - FIXED. A deliquescent neutral salt. By solution and crystallization.
  - VOLATILE. A neutral liquor that would not crystallize.
- METALS.
  - SILVER *. By solution. The calx of silver precipitated from aqua fortis by alkalis; but does not act upon it in its metallic state.
  - COPPER. Beautiful green crystals. By dissolving and crystallizing calcined copper. It acts slowly upon it in its metallic state.
  - IRON. A metallic salt. It dissolves this metal with great facility.
  - LEAD *. A salt resembling Saccharum Saturni. By dissolving the red calx of lead. But it does not act upon it in its metallic state.
- SEMI-METAL. ZINC. Elegant crystals. By the ordinary means.
- The effects of this acid upon other bodies, or the uses to which these combinations might be applied, are not yet sufficiently known.

ACID of BORAX.

- ALKALI. FOSSILE. *Borax.* A native substance, which may be imitated by art. It is of great use in promoting the fusion of metals and earths.
- ALCOHOL. A solution with a considerable heat, which burns with a green flame.
- WATER. A solution in a considerable heat. The other mixtures with this acid not known.

ACID of ANIMALS. We know as yet but little of the nature of this acid; and its combinations with other bodies have not hitherto been examined.

The FIXED ALKALI, whether VEGETABLE or FOSSILE, can be united with the following bodies; but the vegetable is best known.

- ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable; and acid of Urine, of Amber, of Ants, of Borax; as in the former part of this table.
- ALKALIS of all sorts. The uses of these mixtures are not known.
- OILS.
  - EXPRESSED. *Soap.* The best hard soap is made of olive-oil and fossile alkali. The ordinary white soap of this country is made of tallow and potash; black soap, with whale-oil and potash.
  - ESSENTIAL. *Saponaceous mass.* Best made by pouring spirit of wine upon caustic alkali and then oil, digesting and shaking.
  - EMPYREUMATIC. This mixture dissolves gold when precipitated from aqua regia; and is the basis of the fine colour called *Prussian blue;* and has various other properties, as yet but little known.
  - FOSSILE. This has no name, nor are the properties well known; but from some observations that have been made on native soapy waters, it is probable that it would keep linen much longer white than any other kind of soap.
- SULPHUR.
  - *Hepar sulphuris.* By injecting alkalis upon melted sulphur.
  - *Lac sulphuris.* By dissolving sulphur in an alkaline lixivium, and precipitating by an acid.
- METALS.
  - GOLD *. After having precipitated it from aq. regia it dissolves it, if the alkali has been calcined with animal-substances.
  - SILVER *. After having precipitated it from the nitrous acid, it dissolves it if the alkali has been calcined in contact with the flame.
  - TIN. A corroded powder. By the ordinary means of solution.
  - COPPER. By ditto.
  - LEAD. A fluid solution. By ditto. This stains hair black.
  - IRON *. A blood-coloured solution. By dropping a solution of iron in the nitrous acid, into an alkaline lixivium.
- SEMI-METALS.
  - MERCURY *. A fluid solution. After precipitating it from acids; if the alkali is in too large proportions, it then dissolves it, especially if the alkali has been calcined in contact with the flame.
  - ZINC *. By solution, after having precipitated it from the nitrous acid.
  - BISMUTH *. By solution, after having precipitated it from the nitrous acid.
  - ANTIMONY.
    - *Kermes mineral.* By dissolving antimony in an alkaline lixivium, filtering, and allowing it to stand in a cool place till it precipitates.
    - *Golden sulphur of antimony.* By dissolving a crude antimony in an alkaline lixivium, and precipitating by an acid.
    - *Hepar antimonii.* By deflagrating crude antimony with nitre.
    - *Crocus metallorum.* Is hepar antimonii pulverised and edulcorated with water.
    - *Diaphoretic antimony.* By deflagrating regulus of antimony with nitre.
    - *Antimoniated nitre.* By dissolving diaphoretic antimony in water, and allowing it to crystallize.
    - *Magistery of antimony.* By precipitating a solution of diaphoretic antimony by adding vinegar.
    - *Regulus antimonii medicinalis.* By fusing crude antimony with alkali. This is not properly a compound of alkali and antimony, but of another kind. But as it is a term much used, it was proper to explain it.
  - ARSENIC *. A metallic arsenical salt. By a particular elective attraction from regulus of antimony and nitre.
- EARTHS.
  - CHRYSTALLINE.
    - *Liquor silicum.* By fusion with twice their weight of alkalis.
    - *Glass.* By fusion with a much smaller proportion of alkali. This is the composition of crystal glass, and all others commonly used.
  - ABSORBENTS. Argillaceous, and all kinds of earths. *Glass.* By fusion; differing in quality according to the nature of the ingredients. Glass is likewise produced with it in fusion with metals.
- WATER. *Alkaline lixivium,* when caustic, or even the ordinary solution of mild alkali, is a fluid of great power in washing, blacking, &c.
- AIR. FIXT. *Mild alkali.* This is the general state in which alkalis are found; but if they are rendered caustic by means of quick-lime or otherwise, they again absorb it from the air, or from many other bodies, by elective attraction. When perfectly mild, this alkali may be made to assume a crystalline form.

The VOLATILE ALKALI, or SPIRIT of SAL AMMONIAC, can be united with these bodies, *viz.*

- ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable; of Urine, of Amber, of Ants.
- ALKALI, as above.
- OILS.
  - EXPRESSED. Has no name. By solution.
  - ESSENTIAL. *Sal volatile oleosum.* By ditto with some difficulty, unless the alkali is in a caustic state.
  - EMPYREUMATIC. A pungent oily substance, of great power in medicine. The principal one of this kind in use is spirit of hartshorn.
  - FOSSILE. A particular kind of soapy substance.
- SULPHUR. Smoking spirit of sulphur. By distilling sal ammoniac, quick-lime, and sulphur.
- ALCOHOL *. By distilling alcohol from volatile alkalis, it acquires a caustic fiery taste; but the union is not complete.
- METALS.
  - GOLD *.
    - *Aurum fulminans.* A powder obtained by precipitating it from aqua regia by volatile alkalis.
    - A liquid solution. By adding a large proportion of alkali after it has been precipitated from aqua regia. This deposites the gold when long exposed to the air. The curious vegetation called *arbor Dianæ* is formed by adding mercury to this solution.
  - SILVER *. A solution. After it has been precipitated from the nitrous acid.
  - COPPER.
    - A blue-coloured solution. By the ordinary means. This when evaporated to driness, and mixed with tallow, tinges the flame green.
    - Sapphire-coloured crystals. By crystallizing the solution.
    - *Venus fulminans.* By evaporating the solution to driness.
    - *Aqua cerulea sapphirina.* By mixing sal ammoniac, quick-lime, and thin plates of copper, with water, and allowing them to remain a night.
  - IRON. By ordinary solution.
  - LEAD. By ditto.
  - TIN. The mixts that are produced by these metals are little known.
- SEMI-METALS.
  - BISMUTH *. By solution, after having precipitated it from the nitrous acid.
  - ANTIMONY.
  - PLATINA *. By solution, after having precipitated it from aqua regia.
  - COBALT. A reddish liquor. By solution.
  - NICKEL. A blue liquor. By ditto.
- WATER. This solution might be of use in washing or bleaching; but, unless in particular cases, would be too expensive. It coagulates with alcohol.
- AIR. FIXT. Mild volatile alkali. The usual state in which it is found; nor has any method yet been discovered of rendering it solid but in this state.

EXPRESSED OILS.

- ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, of Urine, of Amber, as in the foregoing part of this table.
- ALKALIS: Fixt, and Volatile, as above.
- OILS: Effential, Empyreumatic, and Foffile. By mixture; but their ufes are not much known.
- SULPHUR. *Balfam of Sulphur.* By folution in a boiling heat.
- ALCOHOL. After expreffed oils are freed from foap or plaifters, they are foluble in alcohol; but not in their ordinary ftate.
- METALS.
  - TIN *. A kind of plaifter. By folution when the tin is in the ftate of a calx.
  - LEAD *. Ditto. By boiling the calx of lead in oils. This is ufed for cements in water-works. The common white paint is a mixture of this lefs perfect.
- SEMI-METALS. ZINC *. Ditto. By ditto.
- CALCARIOUS EARTHS. Ditto. By mixture when in a cauftic ftate.

ESSENTIAL OILS.

- ACIDS: Vitriolic, Nitrous, &c. as above.
- ALKALIS: Fixt, and Volatile, as above.
- OILS of all kinds. By folution or mixture.
- SULPHUR. A balfam of fulphur. By folution, imperfectly: better by adding effential oils to the folution made by expreffed oils or hepar fulphuris.
- ALCOHOL.
  - Imperfect mixture. By folution.
  - Aromatic waters. By diftillation.
- METALS.
  - COPPER. By folution.
  - LEAD. By ditto.
- WATER. Diftilled water of the fhops. By diftilling recent vegetable fubftances with water.

EMPYREUMATIC OILS.

- ACIDS: Vitriolic, and Nitrous, as above.
- ALKALIS: Fixt, and Volatile, as above.
- OILS of all kinds. By mixture.
- ALCOHOL. By folution. By repeated diftillations the oils are rendered much more fubtile.

FOSSILE OILS.

- ACIDS: Vitriolic, and Nitrous, as above.
- ALKALIS: Fixt, and Volatile, as above.
- OILS of all kinds. By mixture.
- SULPHUR. With fome difficulty, by folution.
- ALCOHOL. - - - By ditto.

SULPHUR.

- ACID *: Vitriolic; with the phenomena above defcribed.
- ALKALIS: Fixt, and Volatile, as above.
- OILS: Expreffed, Effential, and Foffile, as above.
- METALS.
  - SILVER. A mafs of a red like colour. By adding fulphur to red-hot filver, and fufing; found alfo with it in the ftate of an ore.
  - LEAD. A fparkling friable mafs, hardly fufible. By deflagrating fulphur with lead. This in a native ftate forms the ore of lead called *galena.*
  - COPPER. A black brittle mafs; eafily fufed. By adding fulphur to red-hot copper, or ftratifying with fulphur and fufing. Naturally in fome yellow pyrites.
  - IRON.
    - A fpungy-like drofs, eafily fufible. By putting fulphur to red-hot iron. This is alfo found naturally in the common yellow or brown pyrites.
    - A fulminating compound. By mixing filings of iron with fulphur, moiftening them with water, and preffing them hard, they in a few hours burft out into flame. This compofition has been employed for imitating earthquakes.
    - *Crocus martis.* By deflagrating with iron.
    - *Crocus martis aperiens.* By calcining the crocus martis in the fire till it affumes a red appearance.
    - *Crocus martis aftringens.* By pufhing the heat ftill further.
  - TIN. A dark-coloured mafs, refembling antimony. By fufion.
- SEMI-METALS.
  - MERCURY.
    - *Ethiops mineral.* By heating flowers of fulphur, and pouring the mercury upon it, and ftirring it well. Its natural ore is called *cinnabar.*
    - *Factitious cinnabar.* By applying the mercury and fulphur to each other in their pure ftate, and fubliming.
    - *Cinnabar of antimony.* By fubliming corrofive fublimate and crude antimony; or the refiduum, after diftilling butter of antimony.
  - BISMUTH. A faint greyifh mafs, refembling antimony. By fufion. If in its metalline ftate, the fulphur feparates in the cold; but not fo if the calx has been employed.
  - ANTIMONY. *Crude antimony.* By fufion.
  - ZINC *. A very brittle, dark-coloured, fhining fubftance. With fome difficulty, by keeping it long in a moderate fire, and covering it feveral times with fulphur, and keeping it conftantly ftirred.
  - ARSENIC.
    - *Yellow arfenic.* By fufing it with 1-10th its weight of fulphur.
    - *Red arfenic.* By ditto with 1-5th its weight of fulphur.
    - *Ruby of fulphur,* or arfenic, or golden fulphur. By fubliming when the proportions are equal.
    - *Orpiment.* A natural production; not perfectly imitable by art; compofed of fulphur and arfenic. Much ufed as a yellow paint.
  - NICKEL. A compound; compact and hard as lead; of a bright metallic appearance; internally yellow. By fufion.
- WATER. *Gas fylveftræ.* By receiving the fumes of burning fulphur in water. This ought rather to be called a union of the volatile vitriolic acid with water.

ALCOHOL.

- ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, and of Borax, as above.
- ALKALI *: Volatile, as above.
- OILS: Expreffed, Effential, Empyreumatic, and Foffile, as above.
- METALLIC calces, in fome particular cafes.
- WATER. By folution.

GOLD.

- ACIDS: Vitriolic *, Nitrous *, and Muriatic *. In the circumftances and with the phenomena above defcribed.
- ALKALIS: Fixt *, and Volatile *, as above.
- METALS.
  - SILVER. By fufion. And the fame is to be underftood of all the combinations of metals, unlefs particularly fpecified.
  - LEAD. A very brittle mafs. Gold is rendered pale by the leaft admixture with this.
  - TIN. Remarkably brittle. The fmalleft particle of tin falling upon a furnace renders all the gold or filver melted in it extremely brittle.
  - COPPER. Paler and harder than pure gold. This mixture is ufed in all our coins, the copper being called the alloy.
  - IRON. Silver-coloured, hard and brittle; very eafily fufed.
- SEMI-METALS.
  - MERCURY. Soft like a pafte called an *amalgamum.* By folution; it being in this cafe called *amalgamation*; and the fame is to be underftood of the folution of any other metal in quick-filver.
  - ZINC. A bright and whitifh compound, admitting of a fine polifh, and not fubject to tarnifh; for which qualities it has been propofed as proper for making fpeculi for telefcopes.
  - ARSENIC. Brittle; and the gold is thus rendered a little volatile.
  - ANTIMONY. A fine powder for ftaining glafs of a red colour. By calcination.
  - BISMUTH *. A brittle whitifh regulus; volatile in the fire.
  - PLATINA. Ductile, and of a dufky colour. This has been employed to debafe gold, as it is of the fame fpecific gravity, and is not difcoverable by the ufual tefts for difcovering the purity of gold.
  - COBALT.
  - NICKEL. White and brittle.

SILVER.

- ACIDS: Vitriolic *, Nitrous, Muriatic *, Vegetable *, and Acid of Ants *, as above.
- ALKALIS: Fixt *, and Volatile *, as above.
- SULPHUR, as above.
- METALS.
  - GOLD, as above.
  - LEAD. Very brittle.
  - TIN. Extremely brittle, as much fo as glafs.
  - COPPER. Harder than filver alone. Ufed in fmall proportions as alloy in coins.
  - IRON. A hard whitifh compound.
- SEMI-METALS.
  - MERCURY *. By amalgamation with filver-leaf, or calx of filver precipitated by copper, but not by falts. This is ufed for filverizing on other metals, in the fame way as the amalgamum of gold.
  - ZINC. Hard, fomewhat malleable, and of a white colour.
  - ANTIMONY. A brittle mafs.
  - BISMUTH. A whitifh femi-malleable body.
  - ARSENIC. Brittle; the filver being rendered in part volatile.
  - PLATINA. Pretty pure and malleable. Difficult of fufion; and in part feparates when cold.
  - COBALT.
- CHRYSTALLINE EARTHS, and other vitreous matters. A fine yellow opaque glafs. The fineft yellow paint for porcelain is procured from a glafs mixed with filver.

LEAD.

- ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, of Urine, of Ants *, as above.
- ALKALIS: Fixt, and Volatile, as above.
- OILS: Expreffed *, and Effential, as above.
- SULPHUR, as above.
- METALS.
  - GOLD and Silver, as above.
  - TIN. A little harder than either of the metals, and eafily fufed: hence it is ufed as a folder for lead; and it forms the principal ingredients of pewter. If the fire is long continued, the tin floats on the furface.
  - COPPER *. Brittle and granulated, like tempered iron or fteel when broke. By throwing pieces of copper into melted lead. The union here is very flight.
  - IRON *. An opaque brownifh glafs. By a great degree of heat if the iron has been previoufly reduced to the ftate of a calx; but never in its metallic ftate.
- SEMI-METALS.
  - MERCURY *. By amalgamation. Effected only in a melting heat, unlefs fome bifmuth has been previoufly united with the mercury.
  - ZINC. Hard and brittle. By pouring zinc on melted lead. If the zinc is firft melted, and the lead injected upon it, it then deflagrates.
  - ANTIMONY *.
  - BISMUTH. A grey-coloured femi-malleable body, eafily fufed; and thence ufed as a folder for lead or tin.
  - ARSENIC.
    - A grey-coloured brittle mafs; eafily fufed, and extremely volatile.
    - A hyacinth-coloured glafs. By fufion in a confiderable heat. This glafs is eafily fufed; and is a much more powerful flux than pure glafs of lead.
  - PLATINA. Of a leafy or fibrous texture, and purplifh or blue colour, when expofed to the air. If a large proportion of platina is ufed, it feparates in the cold.
  - COBALT. The nature of this compound is not known.
  - NICKEL. A brittle metallic body.
- CRYSTALLINE EARTHS. A thin glafs. By fufion in a moderate heat.

TIN.

- ACIDS: Vitriolic *, Nitrous *, Muriatic, Vegetable *, of Urine, as above.
- ALKALIS: Fixt, and Volatile, as above.
- OIL: Expreffed *, as above.
- SULPHUR, as above.
- METALS.
  - GOLD, Silver, and Lead, as above.
  - COPPER. A brittle mafs. When the copper is in fmall proportions, it is firmer and harder than pure tin. This in right proportions with a little zinc, forms bell-metal.
  - IRON. A white brittle compound. By heating filings of iron red-hot, and pouring melted tin upon them. A metal refembling the fineft filver is made of iron, tin, and a certain proportion of arfenic.
- SEMI-METALS.
  - MERCURY. This amalgamum forms foils for mirrors; and forms the yellow pigment called *aurum mofaicum.* By being fublimed with fulphur and fal ammoniac.
  - ZINC. Hard and brittle. When the zinc is in fmall proportions, it forms a very fine kind of pewter.
  - ANTIMONY *. *Regulus veneris.* By elective attraction from copper and crude antimony.
  - BISMUTH. Bright, hard, and fonorous, when a fmall proportion of bifmuth is ufed. This is very eafily fufed; and employed as a folder.
  - ARSENIC. A fubftance in external appearance refembling zinc.
  - PLATINA. A coarfe hard metal which tarnifhes in the air.
  - COBALT. By fufion.
  - NICKEL. A brittle metallic mafs.
- CRYSTALLINE EARTHS, or other vitreous matters. An opaque white vitreous mafs, which forms the bafis of white enamels.

- ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, of Urine, of Amber, of Ants, as above.
- ALKALIS: Fixt, and Volatile, as above.
- OIL: Effential, as above.
- SULPHUR, as above.
- METALS.
  - GOLD, Silver, Lead *, and Tin, as above.
  - IRON. Harder and paler than copper. [illegible]

SULPHUR, as above.
COPPER. METALS: Gold, Silver, Lead *, and Tin, as above.
METAL. Iron. Harder and paler than copper. Eaſily fuſed.

SEMI-METALS.
- Mercury *. A curious amalgum. Soft at firſt, but afterward brittle. By triturating mercury with verdigris, common ſalt, vinegar, and water.
- Zinc.
  - *Braſs.* Commonly made by cementation with calamine. The larger the proportion of zinc, the paler, harder, and more brittle is the braſs.
  - *Prince's metal, pinſhbeck,* and other metals reſembling gold. By employing zinc in ſubſtance in ſmall proportions. The beſt pinſhbeck about 1-4th of zinc.
  - *Spelter.* A native ſubſtance, found in Cornwall, conſiſting of zinc and copper, and uſed as a ſolder.
- Antimony. By fuſion.
- Bismuth. A paliſh brittle maſs. Somewhat reſembling ſilver.
- Arsenic. *White copper.* By pouring arſenic, fuſed with nitre, upon copper in fuſion. If too large a proportion of arſenic is uſed, it makes the compound black and apt to tarniſh.
- Platina. A white and hard compound, which does not tarniſh ſo ſoon as pure copper, and admits of a fine poliſh.
- Cobalt. White and brittle.
- Nickel. White and brittle, and apt to tarniſh.

IRON.
ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, of Urine, of Amber, of Ants, as above.
ALKALIS: Fixt *, and Volatile, as above.
SULPHUR, as above.
METALS: Gold, Silver *, Lead *, Tin, and Copper, as above.
SEMI-METALS.
- Zinc. A white ſubſtance reſembling ſilver.
- Antimony. The magnetic quality of the iron is totally deſtroyed in this compound.
- Bismuth. In a ſtrong heat, this emitteth flames.
- Arsenic. A whitiſh, hard, and brittle compound. By fuſing with ſoap or tartar. A metal reſembling fine ſteel is made by fuſing caſt iron with a little arſenic and glaſs.
- Platina. With caſt iron it forms a compound remarkably hard, ſomewhat ductile, and ſuſceptible of a fine poliſh.
- Cobalt. A compound remarkably ductile. By fuſion in a moderate heat.
- Nickel. A brittle maſs.

VITRESCENT EARTHS. A tranſparent glaſs. In general blackiſh; but ſometimes yellow, green, or blue. The colour is influenced by the degree of heat as well as nature of the ingredients.

MERCURY.
ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable *, of Urine, as above.
ALKALI: Fixt *, as above.
SULPHUR, as above.
METALS: Gold, Silver *, Lead *, Tin, and Copper, as above.
SEMI-METALS.
- Zinc. An amalgum. Soft or hard, according to the proportions employed.
- Antimony *. By melting the regulus, and pouring it upon boiling mercury. By frequently diſtilling from this amalgum, the mercury is rendered much more pure, and is then called *animated mercury.*
- Bismuth. A ſilverizing for iron. By putting this amalgum upon iron, and evaporating the mercury. It has much the appearance of ſilver.
- Platina. The compound reſulting from this mixture is not known.
- Cobalt. By mixing firſt with nickel, and then adding mercury.

ZINC.
ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, of Urine, of Amber, of Ants, as above.
OIL: Expreſſed *, as above.
SULPHUR *, as above.
METALS: Gold, Silver, Lead, Tin, Copper, and Iron, as above.
SEMI-METALS.
- Mercury, as above.
- Antimony. This mixture is applied to no particular uſe.
- Arsenic. A black and friable maſs.
- Platina. A hard ſubſtance.
- Cobalt. The particular nature and properties of this mixt is not known.

ANTIMONY.
ACIDS: Vitriolic *, Nitrous, Vegetable *, and Urinous. With the phenomena, and by the means above deſcribed.
ALKALIS: Fixed and Volatile, as above.
SULPHUR, as above.
METALS: Gold, Silver, Lead, Tin *, Copper, and Iron, as above.
SEMI-METALS.
- Mercury, and Zinc, as above.
- Bismuth, A maſs reſembling regulus of antimony.
- Arsenic. The nature and qualities of this mixt are not known.
- Platina. A hard maſs.
- Cobalt. Nature unknown.
- Nickel. Ditto.

VITREOUS EARTHS. A thin penetrating glaſs; which is a powerful flux of metals.

BISMUTH.
ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, and urinous; with the phenomena, &c. above deſcribed.
ALKALIS: Fixed *, and Volatile *, as above.
SULPHUR, as above.
METALS: Gold, Silver, Lead, Tin, Copper, and Iron, as above.
SEMI-METALS.
- Mercury and Antimony, as above.
- Arsenic. Nature not known.
- Platina. This mixture changes its colour much on being expoſed to the air.
- Cobalt *. By mixing firſt with nickel or regulus of antimony, and then adding cobalt; but it cannot be united by itſelf.
- Nickel. This mixt is not known.

VITREOUS MATTERS. A yellow glaſs. The ore of biſmuth affords with theſe a blue glaſs; but this is probably owing to ſome mixture of cobalt with it.

ARSENIC.
ACIDS: Vitriolic, Muriatic *, Vegetable *, and Urinous; with the phenomena, &c. above mentioned.
ALKALIS: Fixt, and Volatile; with the phenomena, and by the means mentioned above.
SULPHUR, as above.
METALS: Gold, Silver, Lead, Tin, Copper, and iron, as above.
SEMI-METALS.
- Zinc, Antimony, and Biſmuth, as above.
- Platina.
- Cobalt.
- Nickel. The phenomena attending theſe mixtures have not been as yet particularly obſerved.

VITREOUS MATTERS. A glaſs which greatly promotes the fuſion of other matters. The arſenic muſt firſt be prepared by diſſolving and precipitating from alkalis.

PLATINA.
ACIDS: Muriatic *; with the phenomena, &c. mentioned above.
ALKALI: Volatile, as above.
METALS: Gold, Silver, Tin, Copper, and Iron, as above.
SEMI-METALS.
- Mercury, Zinc, Biſmuth, and Arſenic, as above.
- Cobalt.
- Nickel. The phenomena attending theſe mixtures not yet obſerved.

COBALT.
ACIDS: Vitriolic, Nitrous, Muriatic, and Urinous; with the phenomena, &c. as above deſcribed.
ALKALI: Volatile, as above.
METALS: Gold, Silver, Lead, Tin, Copper, and Iron, as above.
SEMI-METALS.
- Mercury *, Zinc, Antimony, Biſmuth *, Arſenic, and Platina, as above.
- Nickel. The properties of this compound not known.

EARTHY. Calx of Flint.
- *Zaffre.* By mixing calcined cobalt with calx of flint, and moiſtening them with water, and preſſing them cloſe in wooden tubs.
- *Smalt.* By vitrifying theſe with the addition of a little potaſh.

NICKEL.
ACIDS: Nitrous, and Muriatic; with the phenomena, &c. as mentioned above.
ALKALI: Volatile, as above.
SULPHUR, as above.
METALS: Gold, Lead, Tin, Copper, and Iron, as above.
SEMI-METALS: Antimony, Biſmuth, Arſenic, Platina, and Cobalt, as above.

ABSORBENT EARTHS.
ACIDS: Vitriolic, Nitrous, Muriatic, and Vegetable; with the phenomena, and by the aſſiſtances above mentioned.
ALKALIS: Fixed, as above.
EARTHY.
- Crystalline. By this mixture they are both much eaſier melted into glaſs than by themſelves, but not without the addition of ſome alkali.
- Argillaceous. This mixture eaſily runs into a glaſs without any addition.

WATER. *Lime-water.* By ſolution. It is ſometimes found flowing out of the earth in ſprings; and as it always quits the water when expoſed to the air, it is there depoſited on the banks of the ſtreams, forming the ſtony incruſtations called *petrifications:* And filtring through the pores of the earth, and dropping through the roofs of ſubterraneous caves, it forms the curious incruſtations found hanging from the roof of ſuch places; ſometimes aſſuming forms ſtupenduouſly magnificent.

AIR. Fixt. *Lime-ſtone.* It is from the quality that quick-lime has of abſorbing its air, and again with it reſuming its ſtony conſiſtence, that it is fitted for a cement in building; and the great hardneſs of the cements in old buildings is owing to the air being more perfectly united with theſe than in newer works.

CRYSTALLINE or VITRESCENT EARTHS.
ACIDS: Vitriolic *, and Nitrous *; with the phenomena, &c. as above mentioned.
ALKALI: Fixed, as above.
METALS: Lead, Tin, Copper, and Iron, as above.
SEMI-METALS: Antimony, Biſmuth, Arſenic, and Cobalt, as above.
ABSORBENT EARTHS: as above.
ARGILLACEOUS EARTHS. A maſs running into glaſs in a moderate heat.
WATER. Although this is not ſoluble in water by any operation that we are acquainted with, yet, from its cryſtalline form, it is probable that it has been once ſuſpended; and certainly it is ſo at this day in thoſe petrifying ſprings whoſe incruſtations are of the cryſtalline ſort.

ARGILLACEOUS EARTHS, with Abſorbent and Cryſtalline Earths, as above. With water it only unites into a paſte of a mechanical nature.

EXPLANATION OF THE TABLES.

It was imagined, that a ſyſtematic view of the ſeveral chemical bodies, arranged under diſtinct claſſes, would be of uſe to convey a clear idea of this ſubject to the mind, and ſerve to impreſs it better upon the memory of the reader; and with this view the firſt table was compoſed, the ſeveral parts of which are ſo plain as to admit of no explanation.

The ſame cauſes induced us to think, that a ſyſtematic view of the ſeveral compounds reſulting from the mixture of theſe ſimple bodies would be agreeable to the public; and on that account the ſecond table was compiled; in which we have followed the ſame general arrangement as in the firſt: Shewing, in the firſt place, the ſeveral bodies with which the vitriolic acid can be combined; then proceeding to the nitrous acid, the muriatic, &c. through all the other claſſes, in the ſame order as in the foregoing table.--- In the firſt column, then, on the left hand, is placed a ſimple body, which can be united with ſome one or more individuals of each of thoſe ſpecies which are put in the ſecond column, and the particular ſubſtance of each ſpecies with which it can be united is put in the third column; after which is placed the name and properties of the compound, the operation by which they are united, &c. And in the enumeration of theſe bodies with which any one can be combined, they are placed in the ſame order as is generally obſerved; beginning with acids, and proceeding to alkalis, oils, ſulphur, &c. through all the claſſes. An example of the manner of reading the table will make all this plain.

At the top of the firſt column, on the left hand, is placed the *Vitriolic Acid,* which can be combined with ſome particular kind of each of thoſe ſpecies of bodies enumerated in the ſecond column, included within the crotchet oppoſite to it. By this it appears that it can be combined with acids, alkalis, oils, ſulphur, alcohol, metals, ſemi-metals, earths, and water. The particular kinds of each claſs with which it can be united are placed in the third column; by which it appears, that of the claſs of acids it can be united with the nitrous acid, and with it form a mixture, the only property of which, that has been obſerved, is, that it readily inflames oils. It likewiſe unites with the muriatic and all other acids, as there mentioned. Under the claſs of alkalis, it appears that it can be united with the vegetable, foſſile, and volatile alkalis. With the firſt of which it forms the ſubſtance called *vitriolated tartar,* and the two other ſubſtances there enumerated, by the operations there mentioned. With the foſſile alkali it forms *Glauber's ſalt;* and with the volatile alkali, *ſecret ſal ammoniac;* by the means there mentioned. All the other articles throughout the table are to be read in the ſame manner.

In the ſame way we proceed through the whole of the table, taking each ſimple chemical body in its order, and, placing it in the firſt column, ſhew what others it can be united with. But it is to be obſerved, that as we advance in the table we put down only the names of thoſe ſubſtances which have been already examined; becauſe under each of theſe the particular mixts formed by this union have been already deſcribed. Thus, looking along the firſt column till you come to *Fixt Alkali,* you find in the ſecond column, at the top of the crotchet belonging to this article, *Acids,* and, following it, Vitriolic, Nitrous, Muriatic, &c. with a reference to the foregoing parts of the table; and if you look back to the article *Vitriolic Acid,* under the article *Alkalis* in the ſecond column, you find both the vegetable and foſſile, with the compounds reſulting from this mixture, ſo that it was unneceſſary to repeat it over again under the article *Alkali.* By the ſame means the union of this with the nitrous and other acids are found under each particular acid. And the ſame method is to be obſerved with regard to every reference to the end of the table.

We once propoſed to have omitted mentioning any of theſe articles which had been already deſcribed, from which the references are made; but were induced to place them as in the table, becauſe by means of theſe it is eaſy to ſee, at one view, all the bodies that any one particular body can be united with; whereas, without this, if any one had wanted to know this particular, he behoved to have turned to every article that preceded it. For example, if the article *Biſmuth* was to be examined with this view; turn to it, in the firſt column near the end; at once you ſee with what particular acids, alkalis, ſulphur, and metals, it can be joined with; whereas if theſe had been here omitted, it would have been neceſſary to have conſulted every article preceding it before you could have known which it could, and which it could not be united with.

It is unneceſſary to ſay much about the uſes that may be made of this table, as they are pretty obvious. The principal one is to ſhow, at one view, what bodies any one can be united with, as in the example juſt now given. Again, if it was wanted to know if any one particular ſubſtance could unite with any other particularly ſpecified, it is here at once ſeen. Let it be (*e. g.*) required to know if copper and zinc can be united; turn to the article *Copper* in the firſt column, and ſearch among the ſemi-metals; you there find *Zinc,* and ſee that this compound forms braſs, prince's-metal, and ſpelter. And in the ſame way any other ſubſtance may be examined. If, on the other hand, by glancing along the compounds (which are here printed in italics) you meet with any particular ſubſtance whoſe compoſition you want to know, it is at once diſcovered. Thus, for example, common nitre has catched your eye, of whoſe compoſition you would wiſh to be informed. By looking to the left hand, you find *Vegetable Alkali* (which in the firſt table is ſhown to be the ſame with *Potaſh*); and by looking to the firſt column oppoſite to it, you find the *Nitrous Acid* (or *Aq. Fortis*); from which you at once are informed that it is compoſed of aq. fortis and potaſh.

CHEMOSIS, a diſeaſe of the eyes, proceeding from an inflammation, when the white of the eye ſwells above the black, and overtops it to ſuch a degree, that there appears a ſort of gap between them.

Others define it to be an elevation of the membrane which ſurrounds the eye, and is called the white; being an affection of the eye, like white fleſh.

CHENOPODIUM, in botany, a genus of the pentandria digynia claſs. The calix conſiſts of five leaves; it has no corolla; and there is but one lenticular ſeed. There are 18 ſpecies, 13 of which are natives of Britain, *viz.* the bonus henricus, common Engliſh mercury, or all-good; the urbicum, or upright blite; the rubrum, or ſharp-leaved gooſe-foot; the murale, common gooſe-foot, or ſow-bane; the hybridum, or maple-leaved blite; the album, or common orache; the viride, or green blite; the ſerotinum, or late-flowered blite; the glaucum, or oak-leaved blite; the vulvaria, or ſtinking orache; the polyſpermum, round-leaved blite, or all-ſeed; the maritimum, ſea blite, or white glaſs-wort; and the fruticoſum, ſhrub ſtone-crop, or glaſs-wort. The leaves of the vulvaria, or ſtinking orache, are ſaid to be an excellent anti hyſteric.

CHEPELIO, an iſland in the bay of Panama, and province of Darien, in South America, ſituated about three leagues from the city of Panama, which it ſupplies with proviſions: W. long. 81°, N. lat. 9°.

CHEPSTOW, a market-town in Monmouthſhire, ſituated on the river Wye, near its mouth, about ten miles ſouth of Monmouth: W. long. 2° 40′, N. lat. 51° 40′.

CHEQ, or CHERIF, the prince of Mecca, who is, as it were, high-prieſt of the law, and ſovereign pontiff of all the Mahometans, of whatever ſect or country they be. See CALIPH.

The grand ſignior, ſophies, moguls, khans of Tartary, *&c.* ſend him yearly preſents, eſpecially tapeſtry to cover Mahomet's tomb withal, together with a ſumptuous tent for himſelf, and vaſt ſums of money to provide for all the pilgrims during the ſeventeen days of their devotion.

CHERBURG, a port-town of France, in the province of Normandy, ſituated on a bay of the Engliſh channel, oppoſite to Hampſhire, in England: W. long. 1° 40′, N. lat. 49° 45′.

CHEREM, in Jewiſh antiquity, the ſecond and greater ſort of excommunication among the Jews.

The cherem deprived the excommunicated perſon of almoſt all the advantages of civil ſociety: he could have no commerce with any one, could neither buy nor ſell, except ſuch things as were abſolutely neceſſary for life; nor reſort to the ſchools, nor enter the ſynagogues; and no one was permitted to eat or drink with him.

The ſentence of cherem was to be pronounced by ten perſons, or at leaſt in the preſence of ten: but the excommunicated perſons might be abſolved by three judges, or even by one, provided he were a doctor of the law. The form of this excommunication was loaded with a multitude of curſes and imprecations, taken from different parts of the ſcripture.

CHERESOUL, the capital of Curdiſtan, in Aſiatic Turky, and the ſeat of the beglerbeg, or viceroy, of the province: E. long. 45°, N. lat. 36°.

CHERLERIA, in botany, a genus of the decandria trigynia claſs. The calix conſiſts of five leaves; it has five petals leſs than the leaves of the calix, and five bifid nectaria; the antheræ are alternately barren; and the capſule has three cells and as many valves. There is but one ſpecies, *viz.* the ſedoides, a native of Switzerland.

CHERLESQUIOR, in Turkiſh affairs, denotes a lieutenant-general of the Grand Signior's armies.

CHERMES, in zoology, a genus of inſects belonging to the order of inſecta hemiptera. The roſtrum is ſituate on the breaſt; the feelers are longer than the breaſt; the four wings are deflected; the breaſt is gibbous; and the feet are of the jumping kind. There are 17 ſpecies, and the trivial names are taken from the plants which they frequent, as the chermes graminis, or graſs-bug; the chermes ulmi, or elm-bug, *&c.*

CHERRY TREE, in botany. See PRUNUS.

CHERRY-ISLE, in geography, an iſland ſituated in the north or frozen ocean, between Norway and Greenland: E. long. 20°, N. lat 75°.

CHERSO, the capital of an iſland of the ſame name, in the gulf of Venice, and ſubject to the Venetians: E. long 15°, N lat 45° 25′.

CHERSONESUS, among geographers, the ſame with a peninſula. See PENINSULA

CHERTSEY, a market-town of Surry, about ſeven miles weſt of Kingſton: W. long. 30′, N. lat. 51° 25′.

CHERUB, or CHERUBIN, a celeſtial ſpirit, which in the hierarchy is placed next to the ſeraphim. See HIERARCHY.

The ſeveral deſcriptions which the ſcripture gives us of cherubins, differ from one another; but all agree in repreſenting a figure compoſed of various creatures, as a man, an ox, an eagle, and a lion.

CHERVIL, in botany. See CHÆROPHYLLUM.

CHERWEL, a river, which, ariſing in Northamptonſhire, runs ſouthwards by Banbury, and unites its waters with thoſe of the Iſis, near Oxford.

CHESHAM, a market-town of Buckinghamſhire, about nine miles ſouth-eaſt of Aileſbury: W. long. 35′, N. lat. 51° 36′.

CHESHIRE, a maritime county of England, bounded by Staffordſhire on the eaſt, and by the Iriſh ſea on the weſt: its chief commodities are ſalt and cheeſe, the laſt of which is much eſteemed all over Britain.

CHESNUT-TREE, in botany. See FAGUS.

CHESS, an ingenious game, performed with different pieces of wood, on a board divided into ſixty-four ſquares or houſes; in which chance has ſo ſmall a ſhare, that it may be doubted whether a perſon ever loſt but by his own fault.

Each gameſter has eight dignified pieces, *viz.* a king, a queen, two biſhops, two knights, and two rooks; alſo eight pawns: all which, for diſtinction ſake, are painted of two different colours, as white and black.

As

As to their difpofition on the board, the white king is to be placed on the fourth black houfe from the corner of the board, in the firft and lower rank; and the black king is to be placed on the fourth white houfe on the oppofite or adverfary's end of the board. The queens are to be placed next to the kings, on houfes of their own colour. Next to the king and queen, on each hand, place the two bifhops; next to them, the the two knights; and laft of all, on the corners of the board, the two rooks. As to the pawns, they are placed without diftinction, on the fecond rank of the houfe, one before each of the dignified pieces.

Having thus difpofed the men, the onfet is commonly begun by the pawns, which march ftraight forward in their own file, one houfe at a time, except the firft move, when it can advance two houfes, but never moves backwards: the manner of their taking the adverfary's men, is fide-ways, in the next houfe forwards; where having captivated the enemy, they move forward as before. The rook goes forward or crofs-ways through the whole file, and back again. The knight fkips backward and forward to the next houfe, fave one, of a different colour, with a fidling march, or a flope, and thus kills his enemies that fall in his way, or guards his friends that may be expofed on that fide. The bifhop walks always in the fame colour of the field that he is placed in at firft, forward and backward, aflope, or diagonally, as far as he lifts. The queen's walk is more univerfal, as fhe takes all the fteps of the before-mentioned pieces, excepting that of the knight; and as to the king's motion, it is one houfe at a time, and that either forward, backward, floping, or fide-ways.

As to the value of the different pieces, next to the king is the queen, after her the rooks, then the bifhops, and laft of the dignified pieces comes the knight. The difference of the worth of pawns, is not fo great as that of noblemen; only, it muft be obferved, that the king's bifhop's pawn is the beft in the field, and therefore the fkilful gamefter will be careful of him. It ought alfo to be obferved, that whereas any man may be taken, when he falls within the reach of any of the adverfary's pieces, it is otherwife with the king, who, in fuch a cafe, is only to be faluted with the word *check*, warning him of his danger, out of which it is abfolutely neceffary that he move; and, if it fo happen that he cannot move without expofing himfelf to the like inconveniency, it is check-mate, and the game is loft.

CHEST, in commerce, a kind of meafure, containing an uncertain quantity of feveral commodities.

A cheft of fugar, *v. g.* contains from ten to fifteen hundred weight; a cheft of glafs, from two hundred to three hundred feet; of Caftile foap, from two and an half to three hundred weight; of indigo, from one and an half to two hundred weight, five fcore to the hundred.

CHEST, or THORAX, in anatomy. See p. 277.

CHESTER, the capital city of Chefhire, fituated fixteen miles fouth of Liverpool: W. long. 3°, N. lat. 53° 15′. It is a bifhop's fee, and gives the title of earl to the prince of Wales.

New-CHESTER, the capital of a county of the fame name in Penfilvania, in North America, fituated on the river Delawar, fouth of Philadelphia: W. long. 74°, N. lat. 40° 15′. Its harbour is fine and capacious, admitting veffels of any burden.

CHESTERFIELD, a market-town of Derbyfhire, fifteen miles north of Derby, W. long. 1° 25′, N. lat. 53° 20′. It gives the title of earl to a branch of the noble family of Stanhope.

CHEVALER, in the menage, is faid of a horfe when in paffaging upon a walk or trot, his off fore-leg croffes or overlaps the near fore-leg every fecond motion.

CHEVALIER, in a general fenfe, fignifies a knight, or horfeman.

CHEVAUX DE FRISE, in fortification, a large joift, or piece of timber, about a foot in diameter, and ten or twelve in length, into the fides whereof are driven a great number of wooden pins, about fix foot long, armed with iron points, and croffing one another. See FORTIFICATION.

CHEVERON, in heraldry. See CHEVRON.

CHEVIL. See KEVIL.

CHEVIOT, or TIVIOT-HILLS, run from north to fouth through Cumberland, and were formerly the borders or boundaries between England and Scotland, where many a bloody battle has been fought between the two nations, one of which is recorded in the ballad of Chevy-chafe.

CHEVISANCE, in law, denotes an agreement or compofition, as an end or order fet down between a creditor and his debitor, *&c.*

In our ftatutes, this word is moft commonly ufed for an unlawful bargain, or contract.

CHEVRON, or CHEVERON, in heraldry, one of the honourable ordinaries of a fhield, reprefenting two rafters of an houfe, joined together as they ought to ftand; it was anciently the form of the priefteffes head attire: fome fay, it is a fymbol of protection; others, of conftancy; others, that it reprefents knights fpears, *&c.* It contains the fifth part of the field, and is figured as in Plate LV. fig. 3.

A chevron is faid to be abafed, when its point does not approach the head of the chief, nor reach farther than the middle of the coat; mutilated, when it does not touch the extremes of the coat; cloven, when the upper pieces are taken off, fo that the pieces only touch at one of the angles; broken, when one branch is feparated into two pieces; couched, when the point is turned towards one fide of the efcutcheon; divided, when the branches are of feveral metals, or when metal is oppofed to colour; inverted, when the point is turned towards the point of the coat, and its branches towards the chief.

Per CHEVRON, in heraldry, is when the field is divided only by two fingle lines, rifing from the two bafe points, and meeting in the point above, as the chevron does.

CHEVRONED,

CHEVRONED, is when the coat is filled with an equal number of chevrons, of colour and metal.

CHEVRONEL, a diminutive of chevron, and as such only containing half a chevron.

CHEVRONNE, or CHEVRONNY, signifies the dividing of the shield several times chevron-wise.

CHEWING-BALLS, a kind of balls made of asafœtida, liver of antimony, bay-wood, juniper-wood, and pellitory of Spain; which being dried in the sun, and wrapped in a linen-cloth, are tied to the bit of the bridle for the horse to chew: they create an appetite; and it is said, that balls of Venice treacle may be used in the same manner with good success.

CHIAMPA, the south division of Cochin-china, a country of the East-Indies.

CHIAN *earth*, in pharmacy, one of the medicinal earths of the ancients, the name of which is preserved in the catalogues of the materia medica, but of which nothing more than the name has been known for many ages in the shops.

It is a very dense and compact earth, and is sent hither in small flat pieces from the island of Chios, in which it is found in great plenty at this time. It stands recommended to us as an astringent. They tell us, it is the greatest of all cosmetics, and that it gives a whiteness and smoothness to the skin, and prevents wrinkles, beyond any of the other substances that have been celebrated for the same purposes.

CHIAPA, the capital of a province of the same name in Mexico, situated about 300 miles east of Acapulco: W. long. 98°, N. lat. 16° 30′.

CHIARASCO, a fortified town of Peidmont in Italy, situated on the river Tanaro, twenty miles south-east of Turin, and subject to the king of Sardinia: E. long. 7° 45′, N. lat. 44° 40′.

CHIARENZA, a port-town of the north-west coast of the Morea, opposite to the island Zant, in the Mediterranean, and subject to the Turks: E. long. 21° 15′, N. lat 37° 35′.

CHIARO-SCURO, among painters. See CLARO-OBSCURO.

CHICHESTER, the capital city of Sussex, situated fifty-two miles south-west of London, and twelve miles east of Portsmouth: W. long. 50′, and N. lat. 50° 50′. It is a bishop's see, and sends two members to parliament.

New CHICHESTER, a port-town of Pensilvania, situated on the river Delawar, below Chester. See CHESTER.

CHICK, or CHICKEN, in zoology, denotes the young of the gallinaceous order of birds, especially the common hen. See PHASIANUS.

CHICKEN-*pox*. See *Small*-POX, and MEDICINE.

CHICK-*weed*, in botany. See ALSINE.

CHICKLING-*pea*, in botany, a name given to the lathyrus. See LATHYRUS.

CHICUITO, or CUYO, a province of South America, bounded by the province of La Plata on the northeast, and by Chili on the west.

CHIDLEY, or CHIMLEY, a market-town of Devonshire, about eighteen miles north-west of Exeter: W. long. 4°, N. lat. 51°.

CHIEF, a term signifying the head or principal part of a thing or person. Thus we say, the chief of a party, the chief a family, *&c.*

CHIEF, in heraldry, is that which takes up all the upper part of the escutcheon from side to side, and represents a man's head. See Plate LXV. fig. 4.

It is to take up just the third part of the escutcheon, as all other honourable ordinaries do, especially if they are alone on the shield; but if there be several of them, they must be lessened in proportion to their number, and the same holds when they are cantoned, attended and bordered upon by some other figures; then the painter or engraver may be allowed to bring them into a smaller compass, to the end that all that is represented about the ordinaries may appear with some proportion and symmetry. Chiefs are very much varied, for they may be couvert, supported, crenellé, surmounted, abaisé, rempli, dentillé, engreslé, canellé, danché, nebulé, fleurdelezée, fleuronné, vair, echequeté, lozangé, burellé, patté, fretté, gironné, chaperonné, chappé, mantelé, emmanché, chaussé, vestu or revestu. See COUVERT, SUPPORTED, *&c.*

In CHIEF, imports something borne in the chief part or top of the escutcheon.

CHIEF *lord*, the feudal lord, or lord of an honour on whom others depend.

CHIEF-*justice of the king's bench and common pleas.* See JUSTICE.

CHIEFTAIN, denotes the captain, or chief, of any class, family, or body of men: thus, the chieftains, or chiefs, of the highland clans, were the principal noblemen or gentlemen of their respective clans.

CHIERI, a fortified town of Peidmont in Italy, situated eight miles east of Turin: E. long. 7° 45′, N. lat. 44° 50′.

CHILBLAINS, in medicine. See PERNIO.

CHILD-*bed.* } See MIDWIFERY.
CHILD-*birth.* }

CHILDERMAS-*day*, or INNOCENT'*s-day*, an aniversary held by the church, on the 28th of December, in commemoration of the children at Bethlehem, massacred by order of Herod.

CHILI, a province of south America, bounded by Peru on the north, by the province of La Plata on the east, by Patagonia on the south, and by the Pacific ocean on the west; lying between 25° and 45° S. lat. and between 75° and 85° W. long. But some comprehend Patagonia in Chili, extending it to cape Horn, in 57° 30′ S. lat.

CHILIAD, denotes a thousand of any things, ranged in several divisions, each whereof contains that number.

CHILIARCHA, or CHILIARCHUS, in antiquity, a military officer, who had the command of a thousand men.

CHILIASTS, in church-history. See MILLENARIANS.

CHILMINAR, CHELMINAR, or TCHELMINAR, the most beautiful piece of architecture remaining of all antiquity, being the ruins of the famous palace of Persepolis, to which Alexander the Great, in a drunken fit, set fire, at the instigation of Thais the courtezan:

the word comes from the Perfian *tchehle minar*, that is to fay, forty towers.

Don Garcias de Silva Figueroa, Pietro della Valle, Sir John Chardin, and Le Brun, have been very particular in defcribing thefe ruins.

There appear, fay they, the remains of near fourfcore columns, the fragments of which are at leaft fix feet high; but there are only nineteen can be called entire, with another detached from the reft, about an hundred and fifty paces: a rock of hard black marble ferves as a foundation to the edifice: the firft plan of the houfe is afcended to by ninety-five fteps, all cut in the rock; the gate of the palace is about twenty feet wide, with the figure of an elephant on one fide, and that of a rhinoceros on the other, thirty feet high, and both of polifhed marble: near thefe animals there are two columns, and not far from thence the figure of a pegafus. After paffing this gate, are found fragments of magnificent columns in white marble, the fmalleft of which are fifteen cubits high, the largeft eighteen, having forty flutings three full inches wide each; from whence we may judge of their thicknefs and other proportions. Near the gate is feen an infcription on a fquare piece of black marble, containing about twelve lines; the characters are of an extraordinary figure, refembling triangles, or pyramids: befides this, there are other infcriptions, the characters of which refemble the Hebrew, Chaldaic, or Syriac; others the Arabic or Perfian; and others, in fine, the Greek characters. Dr Hyde, who hath explained the Greek infcription, by fupplying fome words that are effaced, obferves, that the infcriptions are engraved very negligently, and perhaps by fome foldiers; or if they are the work of an engraver, he thinks that he was from Palmyra, and confequently that they are in the Phœnician tongue: he adds, that as they are in praife of Alexander, they were probably done in the time of that conqueror.

CHILTERN, a chain of chalky hills, running from eaft to weft through Buckinghamfhire.

CHIMÆRA, in geography, a port town of Turky in Europe, fituated at the entrance of the gulph of Venice, in the province of Epirus, about thirty-two miles north of the city Corfu, near which are the mountains of Chimæra, which divide Epirus from Theffaly: E. long. 20° 40′, and N. lat. 40° 20′.

CHIMAY, the name of a great lake, lying in the province of Acham, between the Eaft-Indies and China.

CHIMERA, a fabulous monfter, which the poets feign to have the head of a lion, the body of a goat, and the tail of a dragon; and add, that this odd beaft was killed by Bellerophon. The foundation of the fable was, that in Lycia there was a burning mountain, or vulcano, of this name: that the top of this mountain was feldom without lions, nor the middle, which had very good grafs, without goats; that ferpents bred at the bottom, which was marfhy; and that Bellerophon rendered the mountain habitable.

By a chimera, among the philofophers, is underftood a mere creature of the imagination, compofed of fuch contradictions and abfurdities as cannot poffibly any where exift but in thought.

CHIMES *of a clock*, a kind of a periodical mufic, produced at equal intervals of time, by means of a particular apparatus added to a clock.

CHIMNEY, in architecture, a particular part of a houfe, where the fire is made, having a tube or funnel to carry away the fmoke. See ARCHITECTURE.

CHINA, including Chinefe Tartary, a large empire, fituated between 95° and 135° E. long. and between 21° and 55° N. lat. being accounted two thoufand miles in length, and one thoufand five hundred in breadth; it is bounded by Ruffian Tartary on the north, by the Pacific ocean on the eaft and fouth, and by Tonquin, Tibet, and the territories of Ruffia on the weft. It is ufually divided into fixteen provinces, which will be defcribed in their alphabetical order. In thefe provinces there are computed to be one hundred and fifty-five capital cities, one thoufand three hundred and twelve of the fecond rank, two thoufand three hundred and fifty feven fortified towns, and upwards of ten millions of families, which may amount to about fifty millions of people.

The principal commodities of this country are filk, tea, China ware, Japan-ware, and gold duft; of all which the maritime ftates of Europe import great quantities, fending them filver in return.

CHINA-*root*, in pharmacy, a medicinal root, brought both from the Eaft and Weft Indies, thence diftinguifhed into oriental and occidental; it is the root of a fpecies of fmilax. See SMILAX.

CHINA-*ware*. See PORCELAIN.

CHINCA, a port-town of Peru, in South America, fituated in an extenfive valley, on a river of the fame name, about fixty miles fouth of Lima: W. long. 76°, and S. lat. 13°.

CHIN COUGH, a convulfive kind of cough, which children are chiefly fubject to. See MEDICINE.

CHINESE, in general, denotes any thing belonging to China. See CHINA.

It is obferved by fome, that the Chinefe language has no analogy with any other language in the world: it only confifts of three hundred and thirty words, which are all monofyllables, at leaft they are pronounced fo fhort that there is no diftinguifhing above one fyllable or found in them; but the fame word, as pronounced with ftronger or weaker tone, has different fignifications; accordingly, when the language is accurately fpoke, it makes a fort of mufic, which has a real melody, that conftitutes the effence and diftinguifhing character of the Chinefe tongue.

As to the Chinefe characters, they are as fingular as the language; the Chinefe have not, like us, any alphabet, containing the elements, or, as it were, the principles of their words: inftead of an alphabet they ufe a kind of hieroglyphics, whereof they have above eighty thoufand.

As the Chinefe pretend to an antiquity both with regard to their nation and arts, far beyond that of any other nation, it will not perhaps be unacceptable to give

give a ſhort view of theſe pretenſions, principally extracted from their own writers. But, when any thing is quoted from the Chineſe hiſtory, it is abſolutely neceſſary to attend, 1. To the times purely fabulous and mythological; 2. To the doubtful and uncertain times; and, 3. To the hiſtorical times, when the Chineſe hiſtory, ſupported by indiſputable monuments, begins to proceed on ſure grounds.

1. Some aſcribe to Tiene-hoang, a book in eight chapters, which contains the origin of letters. They add, that the characters uſed by the Sane hoang were natural, without any determinate form, that they were nothing but gold and precious ſtones.

Lieou-jou, author of Ouai-ki, ſays, that Tiene-hoang gave names to the ten *KANE*, and to the twelve *TCHI*, to determine the place of the year: this is meant of the cyclic characters.

Tiene-hoang ſignifies emperor of heaven. They call him alſo *Tiene ling*, the intelligent heaven; *Tſee jun*, the ſon who nouriſhes and adorns all things; and finally *Tchong-tiene-hoang-kune*, the ſupreme king of the middle heaven, *&c.* This Tiene-hoang ſucceeded Pouane-cou.

The Ouai-ki ſays, that Ti-hoang (emperor of the earth), the ſucceſſor of Tiene-hoang, divided the day and the night, and appointed thirty days to make one moon. The book Tong li, quoted in Lopi, adds further, that this emperor fixed the winter-ſolſtice to the eleventh moon. A proof that the Chineſe year was originally very incorrect, and that the courſe of it was regulated only by that of the ſeaſons, is, that for a long time, to expreſs a year, they ſaid a change of the leaves.

This Ti-hoang, ſay they, was father of Tiene-hoang, and of Gine-hoang who follows.

They give Gine-hoang (ſovereign of men) nine brothers, and pretend, that they divided the government among them. They were nine brothers (ſays Yuene-leoa-ſane) who divided the earth among them, and built cities, which they ſurrounded with walls. It was under this prince (ſays Lopi), that there firſt began to be a diſtinction between the ſovereign and the ſubject; they drank, they eat, and the two ſexes united.

After theſe three emperors which we have juſt now named, they place the period named *Ou-long* (the five Long or dragons) compoſed of five different families. But they do not tell us their names, nor the duration of their reigns. In theſe times (ſays an author) men dwelt in the bottom of caves, or perched upon trees as it were in neſts. This fact contradicts the invention of building cities, and ſurrounding them with walls, which they place under the reign of Gine-hoang; but we will meet with many ſuch contradictions in the ſequel.

They ſay nothing of the third Ki. Of the fourth, named *Ho lo*, and compoſed of three families, they ſay, that the Ho-lo taught men to retire into the hollows of rocks. This is all they ſay of it. Neither do they ſay any thing of the fifth Ki, named *Liene tong*, and compoſed of ſix families; of the ſixth Ki, named *Su ming*, and compoſed of four families.

It is a folly to dwell upon the epocha of theſe ſix Ki; nothing is more abſurd. Lopi cites an author who generouſly gives them 1,100,750 years duration; Lopi ſays himſelf, that the five firſt Ki after Gine hoang make in all 90,000 years.

The ſeventh Ki is named *Sune-fei*, and comprehends twenty-two families. But they ſay nothing under all theſe reigns that has any relation to the arts or ſciences. Only under the twenty-ſecond and laſt, named *Tſee-che-chi*, they ſay, that it was not till then men ceaſed to dwell in caves. Is it not a palpable abſurdity, that after ſo many ages, and under kings of whom they relate ſo many wonders, they had not yet found out the art of building huts to ſhelter them from the winds and rains!

The eighth Ki, named *Yne-ti*, contains thirteen families or dynaſties. Tchine-fang-chi, the firſt of this period, reigned after Tſee-che-chi, and founded the firſt family. They ſay, that at the beginning men covered their bodies with leaves and herbs; ſerpents and beaſts were very numerous; the waters which had overflowed, were not yet returned into their channels; and the miſery of mankind was extreme. Tchine-fang taught men to prepare ſkins, to take off the hair with rollers of wood, and uſe them againſt the winds and froſt which incommoded them very much. He taught them alſo to make a kind of web of their hair, to ſerve them as a covering to their heads againſt the rain. They obeyed him with joy; he called his ſubjects *people clothed with ſkins*; he reigned 350 years. To Tchine-fang-chi ſucceeded Chou-chane-chi, then Hai-kouei-chi, of whom they ſay nothing which has any relation to our ſubject.

The fourth prince, who alſo ſucceeded Hai-kouei-chi, was named *Hoene-tune*; he founded the fourth dynaſty, (for each of theſe princes which we have juſt now mentioned, was the founder of a family or dynaſty.) In the hiſtory of this king, Lopi quotes Lao-chene-tſee, who ſpeaks thus:

"The ancient kings wore their hair diſhevelled, without any ornament upon their heads. They had neither ſceptre nor crown, and they governed their people in peace. Being of a beneficent diſpoſition, they cheriſhed all things, and put no perſon to death. Always giving, and never receiving any thing, their ſubjects, without dreading their power as maſters, revered their virtue in their hearts. Then heaven and earth obſerved a moſt beautiful order, and every thing flouriſhed in a ſurpriſing manner. The birds built their neſts ſo low, that they might be reached with the hand; all the animal creation tamely ſubmitted to the will of man. Then the juſt medium was obſerved, and harmony reigned over all. They did not reckon the year by the days. There was no diſtinction between within and without, between mine and thine. In this manner reigned Hoene-tune. But when mankind had degenerated from this happy ſtate, birds and beaſts, inſects and ſerpents, all together, and as it were in concert, made war againſt them."

To this dynaſty of Hoene-tune, ſucceeded that of Tong-hou-chi, containg ſeven kings which are not named. To this fifth dynaſty ſucceeded the ſixth, whoſe founder was Hoang-tane-chi.

The 7th, the dynaſty of Ki-tong-chi *.

The 8th, the dynaſty of Ki-y-chi *.

The

The 9th, the dynaſty of Ki-kiu-chi *.

The 10th, the dynaſty of Hi-ouei-chi *.

The 11th, the dynaſty of Yeou-tſao-chi.

The 12th, the dynaſty of Soui-gine.

The 13th and laſt, the dynaſty of Yong-tching-chi.

Of theſe ſeven kings, or founders of dynaſties, which remain to be conſidered to complete the number of dynaſties included in this eighth period, nothing is ſaid of thoſe marked * that has any relation to our ſubject.

As to Yeou-tſao-chi, founder of the eleventh dynaſty, whoſe reign, ſay they, laſted more than 300 years, and whoſe family, they add, continued more than 100 generations during the ſpace of 12 or 18,000 years: here is what we find recorded.

Hane-tſee ſays, that, in the firſt ages of the world, animals multiplied very faſt; and that men being but few, they could not ſubdue the beaſts and ſerpents.

Yene-tſee ſays alſo, that the ancients, either perched on trees, or ſtretched in hollow caves, poſſeſſed the univerſe, (Tiene-hia, that is to ſay, China). Theſe good kings (continues he) breathed nothing but charity without any ſhadow of hatred. They gave much, and took nothing. The people did not go to pay their court to them, but all the world ſubmitted to their virtues.

Lopi and Ouai-ki ſay almoſt in the ſame words, that, in the moſt remote antiquity, men ſheltered themſelves in the hollows of rocks, that they dwelt in deſerts, and lived in ſociety with all the other creatures. They had no thought of doing any injury to the beaſts, and the beaſts did not think of hurting them. But in the ſucceeding ages they became too wiſe, which made the animals rebel; armed with claws, teeth, horns, and venom, they aſſaulted man, and man was not able to reſiſt them. Yeou tſao reigned then. He was the firſt who built houſes of wood, in the form of birds neſts; he perſuaded men to retire into them to avoid the wild beaſts. They did not know as yet how to cultivate the earth, they lived on herbs and fruits. They drank the blood of animals, they devoured their fleſh quite raw, they ſwallowed the hair and the feathers. This is what they ſay of Yeou-tſao chi: after him comes Soui gine, founder of the 12th dynaſty.

Soui-gine chi is eſteemed the inventor of fire.

On the ſummit of the mountain Pou-tcheou, ſays an author, are to be ſeen the walls of Juſtice. The ſun and the moon cannot approach them; there is no difference of ſeaſons there, nor viciſſitudes of days and nights. This is the kingdom of light on the confines of Siouang mou. A ſaint (a great man) went to make a tour beyond the bounds of the ſun and moon: he beheld a tree, and upon that tree a bird, who made fire come out of it by picking it. He was ſurpriſed at this; he took a branch of this tree, and from thence ſtruck fire; from whence they called this great perſonage *Soui-gine*.

Other authors ſay alſo, that Soui-gine made fire with a certain kind of wood, and taught men to dreſs their victuals. By this means all diſeaſes, and all diſorders of the ſtomach and bowels were prevented. In this he followed the direction of heaven, and from thence was named *Soui-gine*.

They ſay further, that, in the days of Soui-gine, there was much water upon the earth, and that this prince taught men the art of fiſhing. He muſt, of conſequence, have invented nets or lines, which invention is after this aſcribed to Fou-hi.

One Long ma, or Dragon-horſe, brought him a kind of table, and the tortoiſe letters. Soui-gine is the firſt to whom they apply this event, but the ſame thing will be ſaid in the ſequel of ſeveral others.

Soui-gine was the firſt who gave names to plants and animals; and theſe names (ſay they) were ſo expreſſive, that the nature of every thing was known by its name. He invented weights and meaſures for the regulation of commerce, which had been unknown before him.

Anciently (ſays an author) men married at fifty, and women at thirty years of age: Soui-gine ſhortened this period, and appointed that young men ſhould marry at thirty, and girls at twenty.

Laſtly, the Liki ſays, that it was Soui-gine who firſt taught men urbanity and politeneſs.

It now remains to ſpeak of Yong tching-chi, the founder of the thirteenth and laſt dynaſty of this period.

In his time, they uſed ſlender cords on which they tied various knots, and this ſerved them inſtead of writing. But, after the invention of letters, how could they return again to the uſe of theſe cords, which is ſo limited and imperfect? This evidently implies a contradiction?

We come now to the ninth Ki or period, named *Chene-tong*. This ninth period will bring us down to the times of Fou hi. It comprehends twenty-one kings, whoſe names are as follow:

1. Sſe hoang, or Tſan hie,	12. Hiene-yuene,
2. Pe-hoang-chi,	13. He ſou,
3. Tchong hoang-chi,	14. Kai-tiene,
4. Tai-ting-chi,	15. Tſune liu chi,
5. Kouene liene,	16. Tcho jong,
6. Yene-chi,	17. Hao-yng,
7. Tai chi,	18. Yeou-tſao-chi,
8. Tching hoei-chi,	19. Tchu-ſiang-chi,
9. Li lou, or Hoei-chi,	20. Yne khang-chi,
10. Sohoang chi,	21. Vou hoai-chi.
11. Nuei-touane-chi,	

Liu-pou-ouei ſays plainly, that Sſe-hoang made letters. This Sſe-hoang, is called alſo *Tſang hie*. Some hiſtorians place him under Hoang-ti, whoſe miniſter they make him; while others make him a ſovereign prince, and much anterior to Hoang-ti.

The firſt inventor of letters was Tſang-hie, then the king Vou-hoai made them be engraved on the coin, and Fou-hi uſed them in the public acts for the government of the empire. But obſerve, that theſe three emperors were even before Chini-nong; how can it be ſaid then, that letters were not invented till under Hoang-ti? Such is the reaſoning of Lopi, who was quite confounded with theſe fabulous times.

To this criticiſm it may be anſwered, You have told us, that letters had been invented in the reign of Soui-gine, the 12th king of the eighth period; how then can you pretend to give the honour of this invention to

Tſang-

Tſang-hie, who, according to your own teſtimony, did not flouriſh till the ninth period? However this may be, Sſee-hoan (ſay ſome romancers) knew to form letters the moment he was born. He was endowed with great wiſdom, *&c.* After he had received the Ho-tou, he viſited the ſouth, went upon mount Yang-yu, and ſtopped on the bank of the river Lo. A divine tortoiſe carrying blue letters upon his ſhell, delivered them to him: then Sſee-hoang penetrated all the changes of heaven and earth; above he obſerved the various configurations of the ſtars; below he examined all the marks he had ſeen upon the tortoiſe; he viewed the plumage of birds, he took notice of the mountains, and of the rivers which flow from them, and of all this he compoſed letters. Some very learned Chineſe think, that this was the ancient kind of writing named *Ko-teou-chu*, which continued (ſay they) to the reign of the emperor Suene-ouang, that is, to the year 827 before J. C.

But Cong-yng-ta very well obſerves, that though the external figures of the letters have changed ſeveral times in ſome things, the ſix rules on which Tſang-hie formed them, have never ſuffered any change.

Then (continues Lopi) there was a difference between the ſovereign and the ſubject, relation between the father and the ſon, diſtinction between the precious and the vile; laws appeared, rites and muſic reigned. Puniſhments were inflicted with vigour. Thus Sſee-hoang laid the foundations of good government, he appointed officers for each affair, the ſmalleſt did not eſcape him; and thus heaven and earth arrived at their full perfection.

They ſay nothing of the ſucceſſor of Sſee-hoang which has any relation to our ſubject; but they ſay, that, under the reign of Tchong-hoang-chi, the third king of this period, they ſtill uſed ſlender cords for writing.

From this prince we come at once to Hiene-yuene, the 12th in order of this period, becauſe nothing is ſaid of his predeceſſors.

We find a great many things under the reign of this prince, becauſe he is the ſame with Hoang-ti, or at leaſt they have confounded theſe two princes together.

They aſcribe to Hiene-yuene the invention of cars. He joined two pieces of wood together, the one placed upright, and the other acroſs, to the honour of the Moſt High. It is from this he is called *Hiene-yuene.* The piece of wood placed acroſs is called *hiene*, and that which is placed upright is called *yuene.* Hiene-yuene ſtruck copper money, and made uſe of the balance to determine the weight of things. By this means he ruled the world in peace. *Ho* ſignifies merchandiſe in general. Formerly they wrote ſimply *hoa*, which ſignifies exchange. Theſe merchandiſes (ſay they) conſiſted in metal, *kine*, in precious ſtones, *yu*, in ivory, *tchi*, in ſkins, *pi*, in coined money, *tſuene*, and in ſtuffs, *pou*, &c.

They then denominated money (as is done ſtill) by the name of the reigning family. That of Hiene-yuene was one inch ſeven lines, and weighed twelve *tchu*, [the *tchu* is the 20th part of a *yo*, and a *yo* weighs 1200 little grains of millet]. They then ingraved letters on their money (as is ſtill done at preſent.) It is for this reaſon that *ven-tſee*, letters, ſignifies alſo a piece of money, which is called likewiſe *kini*, and *tſuene*, and *tao.*

Tcho-jong (16th emperor of the 9th period) hearing, at Cane-tcheou, the ſinging of birds, compoſed a muſic of union, whoſe harmony penetrated every where, touched the intelligent ſpirit, and calmed the heart of man, in ſuch a manner, that the external ſenſes were ſound, the humours in equilibrio, and the life very long. He called this muſic *Tſie-ouene*, that is to ſay, temperance, grace, and beauty.

But the deſign, and in ſome ſort the only aim of the ancient muſic of the Chineſe, according to their authors, was the harmony of the virtues, the moderation of the paſſions, elegance of manners, and, in a word, every thing that can contribute to the perfection of a good and wiſe government, *&c.* For they were perſuaded that muſic was capable of working all theſe miracles. It is difficult for us to believe them in this, eſpecially when we conſider the muſic which is at preſent uſed among them. But we appeal to the Greeks, who related as aſtoniſhing effects from this agreeable invention, whilſt the modern Greeks, like moſt part of the Orientals, have no muſic but a wretched and contemptible monotony.

The 17th king of the 9th period is named *Hao-yng.* In his time they cut down the branches of trees to kill beaſts with. Men were few. Nothing but vaſt foreſts were every where to be ſeen, and theſe frightful woods were filled with wild beaſts. How contradictory is this, and how incompatible with the times in which this prince is ſaid to have reigned!

The 18th king of the 9th period is called *Yeou-tſao-chi.* We have ſeen in the preceeding period, a prince of the ſame name. The Ouai-ki places this king at the beginning of the laſt ki, and gives him for ſucceſſor Souigine. At this rate, nine entire periods, or ki, muſt have elapſed before men knew how to build huts, or had the uſe of fire. Lopi follows another method: he has ranged Yeou-tſao-chi and Soui-gine in the preceeding period; and although the king we are now ſpeaking of bears the ſame name, he ſpeaks of him quite differently.

The 19th king of the 9th period is named *Tchu-ſiang-chi.*

They ſay, that he commanded Sſee-kouei to make a kind of guitar with five ſtrings named *ſe*, to remedy the diſorders of the univerſe, and preſerve every thing that had life.

The 20th king of the 9th period is named *Yne-khang-chi.*

In his time, the waters did not flow, the rivers did not purſue their uſual courſe, which occaſioned a great number of diſeaſes.

Yne-khang inſtituted the dances called *Ta-vou* (grand dances), with a view to preſerve health: for, as Lopi ſays, when the body is not in motion, the humours have not a free courſe; matter is amaſſed in ſome part, from whence come diſeaſes, which all proceed from ſome obſtruction.

The Chineſe alſo imagine, that a man's virtues may be known by his manner of touching the lute and drawing the bow, *&c.*

Thus the Chineſe make dances as well as muſic have a reference to good government; and the Liki ſay, that

that we may judge of a reign by the dances which are uſed in it.

The 21ſt and laſt king of the 9th period is named *Vou-hoai-chi*; but they relate nothing of this prince which is worthy of notice.

2. This is all that the fabulous times contain. If theſe times cannot enable us to fix the real epocha of various inventions, (as the Chineſe are ſo full of contradictions about the time of theſe different diſcoveries), we ſee at leaſt from them, that the origin of arts has been much the ſame among them as among other nations. We are now come down to Fou-hi, who is conſidered by the Chineſe hiſtorians as the founder of their monarchy. What they ſay of this prince and his ſucceſſors, has ſome more ſolidity in it than what we have hitherto ſeen.

FOU-HI.

The Ouai-ki, quoted in the Chineſe annals, thus deſcribes the manners of mankind in theſe days. "In the beginning, men differed nothing from other animals in their way of life. As they wandered up and down in the woods, and women were in common, it happened that children never knew their fathers, but only their mothers. They abandoned themſelves to luſt without ſhame, and had not the leaſt idea of the laws of decency. They thought of nothing but ſleeping and ſnoring, and then getting up and yawning. When hunger preſſed them, they ſought for ſomething to eat; and when they were glutted, they threw the reſt away. They eat the very feathers and hair of animals, and drank their blood. They clothed themſelves with ſkins quite hairy. The emperor Fou-hi began by teaching them to make lines for catching fiſh, and ſnares for taking birds. It was for this, that this prince was named *Fou hi-chi*. He taught them further to feed domeſtic animals, and to fatten them for ſlaughter; for which they gave him the ſirname of *Poa-hi-chi*."

It ſeems evident, that the ancient Chineſe had at firſt no other habitation than caves, the hollows of rocks, and natural dens. They were then infected with a kind of inſect or reptile called *iang*; and when they met, they aſked one another, Are you troubled with *iangs?* To this day they make uſe of this expreſſion, in aſking after any perſon's health; *Couei-iang?* What diſeaſe have you? How do you do? *Vou-iang*, I am without *iang*; that is to ſay, I am hearty, in perfect health, without any ailment.

It would be ſuperfluous to relate here, what the Chineſe ſay, in their annals, of the invention of characters, and of *coua*, after what hath been ſaid by F. Couplet and ſo many others on that ſubject. We ſhall only add, that the treatiſe *Hit-ſee* bears, that, at the beginning nations were governed by means of certain knots which they made on ſlender cords: that afterwards the ſaint introduced writing in their place, to aſſiſt the mandarins in performing all their offices, and the people in examining their conduct; and that it was by the ſymbol *Kouai*, that he conducted himſelf in the execution of his work.

Lopi, whom we have ſo often quoted already, ſays, that Fou-hi extracted from the ſymbol of ſix lines every thing that concerned good government. For example, *Li* gave him the hint of making lines for hunting and fiſhing, and theſe lines were a new occaſion of inventing ſtuffs for garments. Lopi adds, that it is a miſtake to imagine, that, in the times of Fou-hi, they ſtill uſed cords tied and knotted, and that books were not introduced till under Hoang-ti.

Fou-hi taught men to rear the ſix domeſtic animals, not only for food, but alſo for victims, in the ſacrifices which they offered to *Chine*, and to *Ki*. They pretend that Fou-hi regulated the rites *Kiao-chene*.

Fou-hi alſo inſtituted marriage: before this the intercourſe of the ſexes was indiſcriminate; he ſettled the ceremonies with which marriages were to be contracted, in order to render this great foundation of ſociety reſpectable. He commanded the women to wear a different dreſs from that of the men, and prohibited a man's marrying a woman of the ſame name, whether a relation or not, a law which is actually ſtill in force.

Fou-hi appointed ſeveral miniſters and officers to aſſiſt him in the government of the empire.

One of theſe officers made the letters, another drew up the calendar, a third built the houſes, a fourth practiſed medicine, a fifth cultivated the ground, a ſixth was the maſter of the woods and waters.

They pretend that Fou-hi applied himſelf very much to aſtronomy. The Tcheou-pi-ſouane ſays, that he divided the heavens into degrees. Lopi takes notice, that properly the heavens have no degrees, but that this term is uſed with relation to the path of the ſun in the courſe of a year.

The period of ſixty years is reckoned due to Fou-hi. The Tſiene-piene ſays plainly, that this prince made a calendar to fix the year, and that he is the author of Kia-tſe. The Sane-fene ſays the ſame thing; and the Hane-li-tchi ſays, that Fou-hi made the firſt calendar by the Kia-tſe; but the Chi-pene aſcribes this to Hoang-ti. This is one of theſe contradictions ſo common in the Chineſe hiſtorians.

The ſame Fou-hi, they ſay, made arms, and ordained puniſhments. Theſe arms were of wood, thoſe of Chin-nong were of ſtone, and Tchi-yeou made ſome of metal.

Fou-hi drained off the waters, and ſurrounded the cities with walls. In the mean time, as Chin-nong is eſteemed the firſt who made walls of ſtone, we muſt ſuppoſe that thoſe raiſed by Fou-hi were only of earth or brick.

Fou-hi gave rules to muſic. Thoſe who aſcribe this fine art to Hoang-ti are deceived (or *vice verſa.*) After Fou-hi had invented fiſhing, he made a ſong for the fiſhers. It was from his example that Chin nong made one for the labourers.

Fou-hi took of the wood of Tong; he made it hollow; and of it made a *kine* (a lyre, or what you pleaſe to tranſlate it) ſeven feet two inches long; the ſtrings were of ſilk, to the number of 27; he commanded this inſtrument to be named *Li*. Others ſay it had but 25 ſtrings,

ſtrings, others 10, and others only 5; (which of them ſhall we believe?) Beſides, others make this inſtrument only three feet ſix inches ſix lines in length.

Fou-hi made this inſtrument, ſay ſome, to ward off inchantments, and baniſh impurity of heart.

He took of the wood of *ſang*, and made alſo a guitar of 36, or rather of 50 ſtrings. This inſtrument ſerved to adorn the perſon with virtues, and to regulate the heart, &c. Laſtly, he made a third inſtrument of baked earth; after which, ſay they, ceremonies and muſic were in high eſteem.

The money which Fou-hi introduced, was of copper, round within to imitate heaven, and ſquare without to reſemble the earth.

He himſelf made trial of many medicinal plants (This is moſt commonly ſaid of Chin nong: but it is pretended, that Chin-nong finiſhed what Fou-hi had begun.)

This is all we read of Fou-hi. Several contradictions will be remarked in moſt of theſe traditions, eſpecially when we come to ſee in the ſequel, that almoſt all theſe inventions are aſcribed to the ſucceſſors of Fou-hi. From hence may be judged what regard is due to the beginnings of the Chineſe hiſtory.

We have ſtill ſome reigns to examine, before we have done with the fabulous and uncertain times.

They ſay of Koung-koung, that he employed iron in making hangers and hatchets.

They aſcribe to Niu-oua (who is the Eve of the Chineſe) ſeveral inſtruments of muſic. The inſtruments *ſeng* and *hoang* ſerved her, ſay they, to communicate with the eight winds. By means of *kouene*, or double flutes, ſhe united all ſounds into one, and made concord between the ſun, moon, and ſtars. This is called *perfect harmony*. Niu-oua had a guitar (*ſe*) of five ſtrings; ſhe made another of 50 ſtrings, whoſe ſound was ſo affecting, that it could not be borne; wherefore ſhe reduced theſe 50 ſtrings to 25, to diminiſh its force.

The emperor Chin-nong is very famous among the Chineſe, by the great diſcoveries which, they ſay, he made in medicine, agriculture, and even in the military art, ſince they believe, that, in the times of *Han*, they had a book of this prince on the military art.

A fondneſs for the marvellous has made ſome ſay, that, at three years of age, he knew every thing that concerned agriculture. The very name *Chin-nong*, in the Chineſe language, ſignifies, *the ſpirit of huſbandry*. Chin-nong took very hard wood, of which he made the coulter of the plough, and ſofter wood of which he made the handle. He taught men to cultivate the earth. They aſcribe to him the invention of wine. He ſowed the five kinds of grains on the ſouth of Mount Ki, and taught the people to make them their food.

Chin-nong commanded that they ſhould be diligent in gathering the fruits which the earth produced. He taught every thing relative to hemp, to the mulberry tree, and the art of making cloth and ſtuffs of ſilk. They owe alſo to Chin-nong the potters and the founders art; others, however, aſcribe pottery to Hoang-ti, and the art of melting metals to Tchi-yeou

Chin-nong invented fairs in the middle of the day. This was the origin of commerce and mutual exchange. He made uſe of money to facilitate trade. He inſtituted feſtivals.

Chin-nong diſtinguiſhed plants, determined their various properties, and applied them ſkilfully in the cure of diſeaſes. They ſay, that, in one day, he made trial of 70 kinds of poiſons, ſpoke of 400 diſeaſes, and taught 365 remedies. This makes the ſubject of a book, intitled, *Pouenetſao*, which they aſcribe to him, and which contains four chapters. Others alledge, and with reaſon, that this book is not ancient. They ſay, with as little truth, that Chin-nong made books ingraved on ſquare plates.

Chin-nong commanded Tſiou-ho-ki to commit to writing every thing relative to the colour of ſick perſons, and what concerned the pulſe, to teach how to examine its motions if they were regular and harmonious, and, for this end, how to feel it from time to time, and acquaint the patient.

Chin-nong compoſed ballads or ſongs on the fertility of the country. He made a very beautiful lyre, and a guitar adorned with precious ſtones, to form the grand harmony, to bridle concupiſcence, to elevate virtue to the intelligent ſpirit, and bring men back to the celeſtial verity.

Chin-nong aſcended a car drawn by five dragons. He was the firſt that meaſured the figure of the earth, and determined the four ſeas. He found 900,000 lys is weſt, and 850,000 is north and ſouth. He divided all this vaſt ſpace into kingdoms.

Among the ſucceſſors of Chin-nong they place Hoang-ti, and the rebel Tchi-yeou, whom they make the inventor of arms of iron, and ſeveral kinds of puniſhments. Tchi-yeou had the power of raiſing miſts and darkneſs extremely thick. Hoang-ti knew not how to attack and overcome him. He accompliſhed it, however, by forming a car, on which he placed a figure whoſe arm of itſelf always turned to the ſouth, in order to point out the four regions. Hoang-ti uſed the lance and buckler.

Tchi-yeou ordered ſabres, lances, and croſs-bows to be made. They aſcribe to Hoang-ti the *kia-tſe*, or cycle of 60 years; or at leaſt Ta-nao made it by his direction.

The Mandarin Tſang-kiai was charged to compoſe hiſtory. Yong-tcheng made a ſphere which repreſented the celeſtial orbs, and diſcovered the polar ſtar.

Li-cheou regulated numbers, and invented an inſtrument for computation, like to, or the ſame with that which is ſtill in uſe in China and India; and of which Martini, in his Decades, and la Loubere, in his voyage to Siam, have given us the deſign and deſcription.

Ling-lune, a native of Yuene-yu, in the weſt of Tahia, (that is, Khoraſſan), took reeds in the valley of Hiai-ki; he cut two of an equal length, and blew into them: this gave occaſion to the invention of bells. He adjuſted twelve of theſe reeds to imitate the ſong of ſong-hoang, the royal bird, (one of the fabulous birds of the Chineſe). He divided theſe reeds into twelve *lu*; ſix ſerved to imitate the ſong of the male, and ſix that of the female. Finally, this man brought muſic to perfection, and explained the order and arrangement of different ſounds. By means of theſe lu-lu, he governed the

the Khi of the Yne and of Yang, he determined the change of the four ſeaſons, and gave calculations for aſtronomy, geometry, and arithmetic.

Yong yuene, by order of Hoang-ti, made twelve bells of copper, which correſponded to the moons, and ſerved to adjuſt the five tones, and fix the ſeaſons, &c. fables.

Hoang ti invented a kind of diadem or tiara, called *Miene*. He ordered a blue and yellow robe to be made for himſelf, in imitation of the colours of heaven and earth. Having viewed the bird *hoei*, and conſidered the variety of its colours, as well as thoſe of the flowers, he made garments be dyed of different colours, to make a diſtinction between the great and ſmall, the rich and poor.

Nin-fong and Tche-tſiang invented mortars for pounding rice; kettles or caldrons: they invented the art of building bridges, and of making ſhoes; they made coffins for the dead; and men reaped great advantages from all theſe inventions. Hoei invented the bow, Y-meou arrows; Khy-pe invented the drum, which made a noiſe like thunder, trumpets and horns, which imitated the voice of the dragon.

Kong-kou and Hoa-hu, by order of the Emperor Hoang ti, hollowed a tree of which they made a ſhip; of the branches of the ſame tree they made oars; and by this means they were able to penetrate into places which ſeemed inacceſſible, and where men had never been.

For the tranſportation of merchandiſe by land, they alſo invented chariots under this reign, and trained oxen and horſes to draw them.

Hoang-ti alſo turned his thoughts to buildings, and gave models of them. He built a temple, called *Ho-kong*, in which he ſacrificed to *Chang-ti*, or to the Supreme Being.

With a view to facilitate commerce, Hoang-ti ſtruck money, called *kine-tao, knife of metal*, becauſe it had the ſhape of the blade of a knife.

Hoang-ti having obſerved that men died before the time fixed by nature, of diſeaſes which carried them off, he commanded Yu-fou, Ki-pe, and Lei-kong, three famous phyſicians of theſe times, to aſſiſt him to determine what remedies were proper for each diſeaſe.

Si-ling-chi, the chief conſort of that emperor, contributed on her part to the good of the ſtate, and taught the people the art of rearing ſilk-worms, of ſpinning their cods, and making ſtuffs of them.

The Ouai-ki takes notice, that Hoang-ti commanded China to be meaſured, and divided into provinces or tcheou. Each *tcheou* was compoſed of ten *che*, each *che* was compoſed of ten *tou*, and each *tou* contained ten *ye*, or ten cities. Theſe ten *ye*, or cities, had each five *ly*, or ſtreets, &c.

The empire of Hoang-ti, which, according to this hiſtorian, ſeems to have been conſiderable, extended on the eaſt to the ſea, on the weſt to Khong tong. It was bounded on the ſouth by Kiang, and on the north by the country of Hoene-jo

They ſay nothing that has any relation to the arts under the three princes who follow Hoang-ti; that is to ſay, under the reigns of Chao-hao, who reigned 84 years; of Tchouene-hio, who reigned 78 years; and of Cao ſine, who reigned 70 years. They obſerve only, that Chao-hao made them beat the watches with a drum: this ſuppoſes that they had then ſome inſtrument for marking the hours. The Se-ki adds, that this emperor levelled the highways, in order to render the mountains acceſſible, and that he cleared the channels of rivers. He made alſo a new kind of muſic, called *Ta-yuene*, to unite men and genii, and reconcile high and low.

3. After having overcome the fatigue of ſo many fabulous traditions, we now come to the hiſtorical times. But before we enter upon them, it will not be improper to make ſome reflections which are abſolutely neceſſary to ſhew how little regard is due to this ſort of traditions. Theſe reflections are thought to be ſo much the more important, as they will help to undeceive a great many people of the miſtake they are in about the Chineſe antiquities.

The Chineſe monarchy begun by three princes, diſtinguiſhed by the title of *Sane-hoang*, that is to ſay the *three Auguſti*. Theſe three Auguſti, according to the moſt generally received opinion, are *Fou-hi*, *Chine-nong*, and *Hoang-ti*. The five emperors, ſucceſſors of the Sane-hoang, are diſtinguiſhed by the title of *Ou-ti*, that is to ſay, *the five emperors*. The five emperors are, *Chao-hao*, *Tchouene-hio*, *Tico*, *Yao*, and *Chune*. This diviſion has been followed by Cong-ngane-coue, the great-grandſon of Confucius, in the eighth generation, and one of the moſt celebrated writers of the dynaſty of Hane. It has been adopted alſo by Hoang-fou-mi, and by moſt part of the beſt writers. The proofs of this opinion are taken partly from the book Tcheou-li, an ancient record, or ſtate of the empire, which many aſcribe to the famous Tcheou-cong, miniſter and brother of Vou-vang, who was the founder of the imperial dynaſty of Tcheou, eleven hundred and ſome odd years before the Chriſtian æra; partly from the commentaries of Tſo-kieou-mine on the Tchune-tſieou of Confucius's maſter. In theſe works, mention is made of the books, Sane-fene, and Ou-tiene, which, they ſay, are the hiſtories of the three Hoang, and of the five Ti: now, the two firſt chapters of Chou-king, which contain an extract of the hiſtories of Yao and of Chune, bore the title of *Tiene-yao* and *Tiene-Chune*; from whence it was concluded, that Yao and Chune were two of the five Ti; conſequently Fou-hi, Ching-nong, and Hoang-ti, were what are called the three Hoang; and Chao-hao, Tchouene-hio, Tico, Yao, and Chune, were the five Ti.

Theſe may perhaps be thought but feeble proofs to ſupport an hiſtorical fact of this kind; but thoſe who are of a contrary opinion, bring nothing to induce us to believe them, rather than Cong-ngane-coue and Hoang-fou mi.

Hou-chouang-hou, in a preface before the Tſiene-piene of Kine gine-chane confeſſes, that we find in the Tcheou-li, the exiſtence of the book of three Hoang, and that of five Ti: but he adds, that we do not find there the names of theſe eight monarchs; that, under the Tſin, they ſpoke of Tiene hoang, of Ti-hoang, and of Gine hoang; that Cong-ngane-coue, in his preface to Chou-

Chou-king, gives Fou hi, Chine nong, Hoang-ti, for the three Hoang, and that he takes Chao hao, Tchouene-hio, Tio, Yao, and Chune for the five Ti; but that we know not on what foundation he does this, since Confucius, in the Kia-yu, distinguishes by the title of *Ti*, all the kings after Fou hi. The same thing is proved by some passages of Tso-chi and of Liu-pou-ouei; from whence they conclude, that Fou-hi, Chine-nong, and Hoang ti are not the three Hoang, and that there are no other Hoang but heaven, earth, and man.

Tchine-huene retrenches Hoang-ti from the number of the Sane-hoang, and puts in his place Niu-oua, whom he ranges between Fou-hi and Chine nong. Others strike out Niu-oua, and put Tcho-yong in the place of Hoang-ti. Niu-oua was the sister of Fou hi, and Fou-hi, they say, reigned 115 years. At what age must this princess have mounted the throne, for they make her succeed her brother?

The famous Se ma-tsiene, to whom the Chinese, from their high esteem of him, have given the name of *Tai-sse-cong*, or *father of history*, will have Hoang-ti, Tchouene-hio, Cao-sine, Yao, and Chune to be the five Ti; and he gave these princes for their predecessors Soui-gine chi, Fou-hi, and Chine-nong, who, according to him, were the three Hoang. This opinion, since his time, has been embraced by several other writers, who depended upon his authority more than upon proofs which he could not produce.

Confucius says in his Kia yu, that the princes who had governed the empire began at Fou hi to take the name of *Ti* or Emperor. The same philosopher says further, in the treatise Hi-tsee, or commentary upon the Y-king, that anciently Fou hi governed China, that Chine nong succeeded him, that after them Hoang-ti, Yao, and Chune were seated on the throne. From so decisive a testimony, Hou-ou-sang, and several others with him, have not doubted, that these five princes named by Confucius were the Ou-ti, or five emperors. As to the Sane-hoang, they admitted Tiene hoang chi, Ti-hoang chi, Gine-hoang chi, as three chiefs of the people who had governed the empire before Fou-hi.

As it is from Tao-sse, that the several authors we have now quoted, have borrowed their idea of this chimerical division of the eight first Chinese emperors, into three Hoang and five Ti, it is necessary to relate what these religious think themselves. They have opinions peculiar to themselves about these first ages of the monarchy. They believe, that at the first there were three Augusti, Sane-hoang; then five emperors, Ou ti; next three kings, Sane-vang; and lastly, five Pa, Ou-pa; that is to say, five chiefs of Regulos.

This order so regularly observed of three and then five, which is repeated twice, shews plainly, that all this has no foundation in truth, but that it is a system invented at pleasure. Wherefore Tou-chong-chu, who lived under the Hane, explained this in an allegorical manner. The three Hoang were, according to him, the three powers, (heaven, earth, and man); The five Ti were the five duties (the duties of king and subject, of father and children, of husband and wife, of elder and younger brothers, of friends); the three Vang were the three lights, (sun, moon, and stars); finally, the five Pa were the five mountains, four of which are situated at the four cardinal points of the empire, and the fifth at the centre. Thus Tong-tchong-chu allegorized this this pretended succession of kings. But Lopi, who relates this explanation, adds, it was not his own. This is a point of criticism of little importance to us; let them, if they please, ascribe it to some other than Tong-tchong-chu; we have still ground to say, that it came from some writer who lived in an age not far from that of Tong-tchong-chu. This is enough for our present purpose, since we see from hence the little regard they then paid to this division, which they considered as chimerical. It would be in vain to attempt to reconcile all these contradictions. All these imaginary reigns are in the manner of the Tao-sse, who have darkened the origin of the Chinese monarchy by their fables and mythology. The ten Ki or periods are of their inventing; they gave them between two and three millions of years duration. But before these ten periods, they place three dynasties, viz. the dynasty of Thiene-hoang-chi, that of Ti-hoang-chi, and finally, that of Gine-hoang-chi. If we attend to the signification of these names, they must be interpreted thus: the *Sovereign of heaven*, the *Sovereign of earth*, the *Sovereign of men*. We see from hence, that the allegorical explanation of Tong-tchong-chu, which made the three Hoang signify the three powers, that is, heaven, earth, and man, is not without probability.

These three Hoang succeeded to Pouane-cou, otherwise Hoene-tune, the chaos, the origin of the world, which several of the Tao-sse take for the first man, or the first king who governed China.

The dynasty of Thiene-hoang-chi had thirteen kings, who reigned, say they, 18,000 years; then came the dynasty of Ti-hoang-chi, whose kings, to the number of eleven, make up a like duration of 18,000 years. Finally, to Ti-hoang-chi succeeded the Gine-hoang-chi, whose dynasty, composed of nine kings, furnishes a space of 45,600 years. These three sums added, give us precisely 81,600 years. But if we add to these three dynasties, those which are comprehended in each of the ten Ki, and which amount, according to some calculations, to more than 230; we shall find that the pretensions of the Chinese very much exceed those of the Chaldeans and Egyptians. For if we believe the calculations of various authors, from Pouane-cou to the death of Confucius, which happened in the year 479 before J. C. there is elapsed 276,000 years, or 2,276,000, or 2.759,860, or even 3,276,000; or, finally, which is a great deal more, 96,961,740 years: for we find all these different calculations.

It is visible enough, that these extravagant numbers can be nothing else but astronomical periods, contrived to give the conjunction of the planets in certain constellations, or calculations which have some relation to the ideas of the Tao sse, concerning the perpetual destructions and reproductions of worlds. In fact, some have endeavoured to make these numbers agree with the period of Tchao-cang-tsie, a famous philosopher in the days of Song, who had undertaken to determine the period of the duration of the world; for the system of the de-

ſtruction and reproduction of worlds was very current, not only in the ſect of Ju or of the learned, but alſo among the Bonzes, Ho-chang or the religious of Fo, and among the Tao-ſſe or followers of Lao-Kiune, that is to ſay, among the three great ſects, who have the moſt influence in the empire. Tchao-cang-tſie eſtabliſhed then a great period of 129,000 years, called *Yuene*, compoſed of twelve equal parts, called *hoei*, or *conjunctions*, which were each of 10,800 years. In the firſt conjunction, ſaid he, heaven was formed by little and little, by the motion which the Tai-ki, or the Supreme Being, impreſſed upon matter which was formerly at perfect reſt. During the ſecond conjunction, the earth was produced in the ſame manner. At the middle of the third conjunction, man and all other beings began to ſpring up, in the manner that plants and trees are produced in the iſlands, which afterwards preſerve their ſeveral kinds by their ſeeds. At the middle of the eleventh conjunction, all things ſhall be deſtroyed, and the world ſhall fall back again into its primitive chaos, from whence it ſhall not ariſe till after the twelfth conjunction is expired.

It is not difficult at preſent to conceive, that the Tao-ſſe had invented that prodigious number of reigns before Fou-hi, for no other reaſon, but to fill up that interval, which, according to them, had elapſed from the production of man, to the beginning of the Chineſe monarchy, that is to ſay, to the reign of Fou-hi. The ſame calculator determined the half of Yuene, or of his great period of 129,000 years, at the reign of Yao.

Theſe Tao-ſſe, as was ſaid already, laid down theſe ten ages or ten Ki as an indiſputable principle; each Ki comprehended ſeveral dynaſties, whoſe duration they determined as they thought fit, and as their calculation required: but if they were at liberty to increaſe or diminiſh the duration of the ten Ki, it was not the ſame as to their number, which was in ſome ſort a fundamental principle of their ſect, from which they were not allowed to depart.

Some miſſionaries, to whom this doctrine of Tao-ſſe was not unknown, imagined, that they diſcerned in theſe ten Ki, the ten generations before Noah; and as the writers cited by Lopi, and by Cong-ing-ta, ſay, that of theſe ten Ki, ſix were before Fou-he, and four after him; theſe ſame miſſionaries have imagined, that Fou-hi was Enoch. It muſt be owned, in the mean time, that Tchine-huene and ſeveral others do not obſerve the ſame order; that they place Chine-nong in the ninth Ki, Hoang-ti in the tenth, *&c.* By this computation Hoang-ti would be Noah, and Fou-hi Methuſelah, which contradicts their hypotheſis.

The opinion which conſiders the ten Ki of the Chineſe as the ten generations which preceded Noah, is very ingenious, and not improbable. Towards the end of the reign of Tcheou, about 300 years before the Chriſtian æra, ſome Jews travelled into China, who might have made the writings of Moſes known there, and, of conſequence, the ten generations which preceded the deluge: beſides, this knowledge was common to the Chaldeans, who might have penetrated into China before the Jews.

CHINEY, a city of the Auſtrian Netherlands, on the confines of the biſhopric of Liege, about twelve miles ſouth-eaſt of Namur: E. long. 5°, N. lat. 50° 20′.

CHINON, a town of France in the province of the Orleanois, about twenty three miles ſouth-weſt of Tours; E. long. 20′, and N. lat. 47° 15′.

CHIO, Chios, Xio, or Scio, an Aſiatic iſland, lying near the coaſt of Ionia, in Natolia or Leſſer Aſia, about one hundred miles weſt of Smyrna. It is called by the Turks Sakiſaduci, and is about one hundred miles in circumference; being chiefly inhabited by Chriſtians of the Greek church, who are ſaid to have three hundred churches in the iſland.

Chio is alſo the capital of the above iſland, ſituated on the eaſt coaſt: E. long. 27°, and N. lat. 38°.

CHIONANTHUS, or snow-drop-tree, in botany, a genus of the diandria-monogynia claſs. The calix divided into four oval ſegments; and the drupa contains but one ſeed. There are two ſpecies, *viz.* the virginica and zeylonica, both natives of the Indies.

CHIOZZO, or Chioggio, a town on an iſland of the ſame name, in the gulph of Venice, by which there is a paſſage into the Lagunes, ſituated about twelve miles ſouth of the city of Venice.

CHIPPENHAM, a borough-town in Wiltſhire, about twenty-two miles north-weſt of Saliſbury: W. long. 2° 12′, and N. lat. 51° 25′. It ſends two members to parliament.

CHIPPING, or Much-Wiccomb, a borough-town of Buckinghamſhire, about ten miles ſouth of Aileſbury: W. long. 42′, and N. lat. 51° 35′. It ſends two members to parliament.

CHIROGRAPHY, a writing under one's own hand.

CHIROMANCY, a ſpecies of divination, drawn from the different lines and lineaments of a perſon's hand; by which means, it is pretended, the inclinations may be diſcovered.

CHIRONIA, in botany, a genus of the pentandria monogynia claſs. The corolla is rotated; the piſtillum declines; the ſtaminæ are inſerted into the tube of the corolla; the antheræ are ſpiral; and the pericarpium is bilocular. There are eight ſpecies, none of them natives of Britain.

CHIRONOMY, in antiquity, the art of repreſenting any paſt tranſaction by the geſtures of the body, more eſpecially by the motions of the hands: this made a part of liberal education; it had the approbation of Socrates, and was ranked by Plato among the political virtues.

CHIROTONY, among eccleſiaſtical writers, denotes the impoſition of hands uſed in conferring prieſtly orders.

However, it is proper to remark, that chirotony originally was a method of electing magiſtrates, by holding up the hands.

CHIRVAN, a province of Perſia, lying on the weſtern coaſt of the Caſpian ſea.

CHIRURGERY. See Surgery.

CHISLEY-LAND, in agriculture, a ſoil of a middle nature between ſandy and clayey land, with a large admixture of pebbles.

CHISSEL, an inftrument much ufed in carpentry, mafonry, joinery, fculpture, *&c.* and diftinguifhed according to the breadth of the blade into half-inch chiffels, quarter-inch chiffels, *&c.* They have alfo different names according to the different ufes to which they are applied; as, 1. The former, ufed by carpenters, *&c.* juft after the work is fcribed: it is ftruck with a mallet. 2. The paring-chiffel, which is ufed in paring off the irregularities made by the former: this is preffed with the workman's fhoulder. 3. The fkew-former cleanfes acute angles with the point of its narrow edge. 4. The mortice chiffel, ufed in cutting deep fquare holes in wood, for mortices: it is narrow, but thick and ftrong, to endure hard blows. 5. Socket-chiffels, having their fhank made with a hollow focket at top, to receive a ftrong wooden fprig fitted into it with a fhoulder. 6. Ripping chiffel, having a blunt edge, with no bafil, ufed in tearing two pieces of woop afunder. And, 7. the gouge. See GOUGE.

CHITAU, in the materia medica, a kind of lignum-aloes, of a reddifh colour. See LIGNUM-ALOES.

CHIVALRY, in law, is a tenure of fervice, whereby the tenant is bound to perform fome noble or military office to his lord; and is either regal, when held only of the king; or common, fuch as may be held of a common perfon as well as the king: the former is properly called ferjeanty, and the latter efcuage.

A ftatute of Charles II. abolifhes all tenures by chivalry, in capite, *&c.* and ordains that all tenures fhall be conftrued to be free and common foccage.

CHIVES, in botany. See ANTHERÆ.

CHIUSI, a city of Italy, in the dutchy of Tufcany, fituated on the confines of the pope's territories, about thirty-five miles fouth-eaft of Sienna: E. long. 13°, and N. lat. 33°.

CHLAMYS, in antiquity, a military habit worn by the ancients over the tunica. It belonged to the patricians, and was the fame in the time of war that the toga was in the time of peace. This fort of gown was called picta, from the rich embroidery with figures in Phrygian-work; and purpurea, becaufe the ground-work was purple. The chlamydes of the emperors were all purple, adorned with a golden or embroidered border.

CHLORIS, in ornithology, the trivial name of a fpecies of Loxia. See LOXIA.

CHLOROSIS, in medicine, a difeafe commonly called the green-ficknefs, incident to young girls. See MEDICINE.

CHOCOLATE, in commerce, a kind of pafte, or cake, prepared of certain ingredients, the bafis of which is the cacao-nut.

The Indians, in their firft making of chocolate, ufed to roaft the cacao in earthen pots; and having afterwards cleared it of the hulks, and bruifed it between two ftones, they made it into cakes with their hands. The Spaniards improved this method: when the cacao is properly roafted, and well cleaned, they pound it in a mortar, to reduce it into a coarfe mafs which they afterwards grind on a ftone, till it be of the utmoft finenefs: the pafte being fufficiently ground, is put quite hot into tin moulds, in which it congeals in a very little time. The form of thefe moulds is arbitrary; the cylindrical ones, holding two or three pounds, are the moft proper, becaufe the bigger the cakes are, the longer they will keep. Obferve, that thefe cakes are very liable to take any good or bad fcent, and therefore they muft be carefully wrapt up in paper, and kept in a dry place. Complaints are made, that the Spaniards mix with the cacao nuts too great a quantity of cloves and cinnamon, befides other drugs without number, as mufk, ambergrife, *&c.* The grocers of Paris ufe few or none of thefe ingredients; they only chufe the beft nuts, which are called Caracca, from the place from whence they are brought, and with thefe they mix a very fmall quantity of cinnamon, the frefheft vanilla, and the fineft fugar, but very feldom any cloves. Among us in England, the chocolate is made of the fimple cacao, excepting that fometimes fugar, and fometimes vanilla is added.

Chocolate ready made, and cacao pafte, are prohibited to be imported from any part beyond the feas. If made and fold in Great Britain, it pays inland-duty 1 s. 6 d. per lb. avoirdupoife: it muft be inclofed in papers containing one pound each, and produced at the excife-office, to be ftamped. Upon three days notice given to the officer of excife, private families may make chocolate for their own ufe, provided no lefs than half an hundred weight of nuts be made at one time.

CHOENIX, a dry meafure, containing a forty-eighth part of a medimnus, or fix bufhels. Hence the celebrated proverb of Pythagoras, *Super chœnice ne fedeas.*

CHOIR, that part of the church or cathedral where choirifters fing divine fervice: it is feparated from the chancel, where the communion is celebrated; and alfo from the nave of the church, where the people are placed: the patron is faid to be obliged to repair the choir of the church.

CHOLEDOCHUS, in anatomy. See Vol. i. p. 265.

CHOLER. See BILE.

CHOLERA *morbus*, in medicine. See MEDICINE.

CHONDRILLA, in botany, a genus of the fyngenefia polygamia æqualis clafs. The calix is caliculated; the receptacle is naked; the pappus is fimple, and furnifhed with a ftipes; and the flofcules are numerous. There is but one fpecies, *viz.* the jancæa, a native of Germany.

CHONDROPTERYGII, in ichthyology, a term formerly applied to the order of fifhes, now called amphibia nantes by Linnæus. See AMPHIBIA.

CHOPIN, or CHOPINE, a liquid meafure, ufed both in Scotland and France, and equal to half their pint. See PINT, and MEASURE.

CHORASSAN, a province of Perfia, on the north-eaft, adjoining to Ufbec Tartary; this was the ancient Bactria, and the native country of the late Kouli Kan.

CHORD, in geometry, a right line drawn from one part of an arch of a circle to the other. Hence,

CHORD *of an arch* is a right line joining the extremes of that arch. See TRIGONOMETRY.

CHORDS, or CORDS, in music, are strings, by the vibration of which the sensation of sound is excited, and by the divisions of which the several degrees of tune are determined.

CHORD is also used in music for the note or tone to be touched or sounded: in this sense the fifth is said to consist of five chords or sounds.

CHORDAPSUS, in medicine, a disease of the intestines, when to the touch they feel like stretched cords: it is the same with the iliac passion.

CHORDEE, in medicine and surgery, a symptom attending a gonorrhœa, consisting in a violent pain under the frenum, and along the duct of the urethra, during the erection of the penis, which is incurvated downwards. These erections are frequent and involuntary. See MEDICINE.

CHOREUS, in ancient poetry. See TROCHEE.

CHORGES, or GORGES, a town of Dauphiny, in France, about six miles east of Gap: E. long. 6°, and N. lat. 44° 36′.

CHORIAMBUS, in ancient poetry, a foot consisting of four syllables, whereof the first and last are long, and the two middle ones are short; or, which is the same thing, it is made up of a trochæus and iambus: such is the word nōbĭlĭtās.

CHORION, in anatomy, the exterior membrane which invests the fœtus in the uterus.

CHOROBATA, or CHOROBATES, a kind of water-level among the ancients, of the figure of the letter T, according to Vitruvius's description.

CHOROGRAPHY, the art of making a map of some country or province.

CHORUS, in dramatic poetry, one or more persons present on the stage during the representation, and supposed to be by standers without any share in the action.

Tragedy in its origin was no more than a single chorus, who trod the stage alone, and without any actors, singing dithyrambics or hymns in honour of Bacchus. Thespis, to relieve the chorus, added an actor, who rehearsed the adventures of some of their heroes; and Æschylus, finding a single person too dry an entertainment, added a second, at the same time reducing the singing of the chorus, to make more room for the recitation. But when once tragedy began to be formed, the recitative, which at first was intended only as an accessory part to give the chorus a breathing time, became a principal part of the tragedy. At length, however, the chorus became inserted and incorporated into the action: sometimes it was to speak, and then their chief, whom they called corryphæus, spoke in behalf of the rest: the singing was performed by the whole company; so that when the coryphæus struck into a song, the chorus immediately joined him.

The chorus sometimes also joined the actors in the course of the representation, with their plaints and lamentations on account of any unhappy accidents that befel them: but the proper function, and that for which it seemed chiefly retained, was to shew the intervals of the acts: while the actors were behind the scenes, the chorus engaged the spectators; their songs usually turned on what was exhibited, and were not to contain any thing but what was suited to the subject, and had a natural connection with it; so that the chorus concurred with the actors for advancing the action. In the modern tragedies the chorus is laid aside, and the fiddles supply its place. Mr Dacier looks on this retrenchment as of ill consequence, and thinks it robs tragedy of a great part of its lustre; he therefore judges it necessary to re-establish it, not only on account of the regularity of the piece, but also to correct, by prudent and virtuous reflections, any extravagancies that might fall from the mouths of the actors, when under any violent passion.

Mr Dacier observed also, that there was a chorus, or grex, in the ancient comedy; but this is suppressed in the new comedy, because it was used to reprove vices by attacking particular persons; as the chorus of the tragedy was laid aside to give the greater probability to those kind of intrigues which require secrecy.

CHORUS, in music, is when, at certain periods of a song, the whole company are to join the singer in repeating certain couplets, or verses.

CHOTZIM, a frontier-town of Moldavia, on the confines of Poland, situated on the river Niester, and subject to the Turks: E. long. 27°, and N. lat. 48°.

CHOUG, a town of Syria, upon the road from Aleppo to Sayde, called by some travellers Shoggle.

CHOUGH, in ornithology. See CORVUS.

CHREMNITZ, the principal of the mine-towns in Upper Hungary, situated about sixty-eight miles north-east of Presburg, and subject to the house of Austria: E. long. 19°, and N. lat. 48° 45′.

CHREMPS, in ichthyology. See SPARUS.

CHRISM, oil consecrated by the bishop, and used in the Romish and Greek churches in the administration of baptism, confirmation, ordination, and extreme unction.

Order of CHRIST, a military order, founded by Dionysius I. king of Portugal, to animate his nobles against the Moors.

The arms of this order are gules, a patriarchal cross, charged with another cross argent: they had their residence at first at Castromarin, afterwards they removed to the city of Thomar, as being nearer to the Moors of Andalusia and Estremadura.

CHRIST is also the name of a military order in Livonia, instituted in 1205, by Albert bishop of Riga. The end of this institution was to defend the new Christians, who were converted every day in Livonia, but were persecuted by the heathens. They wore on their cloaks a sword with a cross over it, whence they were also denominated brothers of the sword.

CHRIST-BURGH, a town of Poland, near the lake Draussen, and about three Polish miles from Marienburgh.

CHRIST-CHURCH, a borough town of Hampshire, thirty miles south-west of Wincester, near the sea-coast: W. long. 2°, N. lat. 50° 40′. It sends two members to parliament.

CHRIST-*thorn*, in botany. See RHAMNUS.

Most

Moſt CHRISTIAN *king*, one of the titles of the king of France.

The French antiquaries trace the origin of this appellation up to Gregory the Great, who, writing a letter to Charles Martlet, occaſionally gave him that title, which his ſucceſſors have ſince retained.

CHRISTIAN *religion*, that inſtituted by Jeſus Chriſt. See RELIGION.

CHRISTIANS, thoſe who profeſs to believe the Chriſtian religion. See RELIGION.

CHRISTIANS *of St John*, a ſect of Chriſtians very numerous in Balſara and the neighbouring towns: they formerly inhabited along the river Jordan, where St John baptized, and it was from thence they had their name. They hold an anniverſary feaſt of five days, during which they all go to the biſhop, who baptizes them with the baptiſm of St John. Their baptiſm is alſo performed on rivers, and that only on Sundays; they have no notion of the third perſon in the Trinity, nor have they any canonical book, but abundance full of charms, *&c.* Their biſhoprics deſcend by inheritance, as our eſtates do, though they have the ceremony of an election.

CHRISTIANS *of St Thomas*, a ſort of Chriſtians in a peninſula of India, on this ſide of the gulf: they inhabit chiefly at Cranganor, and the neighbouring country: theſe admit of no images, and receive only the croſs, to which they pay a great veneration: they affirm, that the ſouls of the ſaints do not ſee God till after the day of judgment: they acknowledge but three ſacraments, *viz.* baptiſm, orders, and the euchariſt: they make no uſe of holy oils in the adminiſtration of baptiſm, but after the ceremony anoint the infant with an unction compoſed of oil and walnuts, without any benediction. In the euchariſt, they conſecrate with little cakes made of oil and ſalt, and inſtead of wine make uſe of water in which raiſins have been infuſed.

CHRISTIANA, a town of Norway, in the province of Aggerhuys, ſituated on a bay of the ſea, a hundred miles north of Gottenburgh: E. long. 10° 15′, N. lat. 59° 30′.

CHRISTIANOPLE, a port-town of Sweden, ſituated on the Baltic ſea, in the territory of Bleking, and province South Gothland, about thirteen miles north-eaſt of Carleſcroon: E. long. 15° 40′, and N. lat. 57°.

CHRISTIANSBURGH, a Daniſh factory upon the gold-coaſt of Africa, near Acra.

CHRISTIANSTADT, a town of Sweden, ſituated on the river Helles, in the territory of Bleking, and province of South Gothland, forty-five miles weſt of Carleſcroon: E. long. 14° 40′, N. lat 56° 30′.

CHRISTMAS, a feſtival of the Chriſtian church, obſerved on the 25th of December, in memory of the nativity of Jeſus Chriſt.

CHRISTOPHER-*herb*, in botany. See CHRISTOPHORIANA.

CHRISTOPHERS, or *St* CHRISTOPHERS, one of the Caribbee iſlands, to which Columbus gave his Chriſtian name: W. long. 62°, N. lat. 71° 30′.

It is about twenty miles long, and ſeven broad; and has a high moun- H R
ſome rivulets run down.
cotton, ginger, and indigo. middle, from whence
and lies about ſixty miles weſt o e is chiefly ſugar,

CHRISTOPHORIANA, in botany. British colony,

CHROASTACES, in natural hiſtory, a ge
cid gems, comprehending all thoſe of variable A.
as viewed in different lights; of which kinds are
opal and the aſteria, or oculus cati. See OPAL, and ASTERIA.

CHROMA, in muſic, a note or character of time, uſually termed a quaver.

Chroma is alſo a graceful way of ſinging, or playing with quavers and trilloes.

CHROMATIC, in the ancient muſic, the ſecond of the three kinds into which the conſonant intervals were ſubdivided into their concinnous parts. The other two kinds are enharmonic and diatonic.

CHROMATIC, in painting, a term uſed to ſignify the colouring, which makes the third part in the art of painting.

CHROMIS, in ichthyology. See SPARUS.

CHRONIC, or CHRONICAL, among phyſicians, an appellation given to diſeaſes that continue a long time, in contradiſtinction to thoſe that ſoon terminate, and are called *acute*. See MEDICINE.

CHRONICLE, in matters of literature, a ſpecies or kind of hiſtory, diſpoſed according to the order of time, and agreeing in moſt reſpects with annals. See ANNALS.

Books of CHRONICLES, in the canon of ſcripture, two ſacred books, called by the Greeks *paralipomena*, that is, remains, additions, or ſupplements, as containing many circumſtances omitted in the other hiſtorical books.

CHRONOGRAM, a ſpecies of falſe wit, conſiſting in this, that a certain date or epocha is expreſſed by numeral letters of one or more verſes: ſuch is that which makes the motto of a medal ſtruck by Guſtavus Adolphus, in 1632.

ChrIſtVs DVX, ergo trIVMphVs.

CHRONOLOGY, the ſcience or doctrine of time, in ſo far as it regards hiſtory, whether civil or eccleſiaſtical.

The buſineſs of chronology, is to aſcertain and adjuſt the various epochas, æras, and other periods mentioned in hiſtory; ſo that the revolutions of empires and kingdoms, and other remarkable events, may be truly ſtated. For the principles of chronology, ſee ASTRONOMY, *Of the diviſion of time.*

CHRONOMETER, in general, denotes any inſtrument or machine, uſed in meaſuring time; ſuch are dials, clocks, watches, *&c.* See CLOCK, DIAL, *&c.*

CHRONOSCOPE, denotes much the ſame with chronometer. See the preceding article.

CHROSTASIMA, in natural hiſtory, a genus of pellucid gems, comprehending all thoſe which appear of one ſimple and permanent colour in all lights: ſuch are the diamond, carbuncle, ruby, garnet, amethyſt, ſapphire, beryl, emerald, and the topaz. See DIAMOND, CARBUNCLE, *&c.*

C H R see Falco.

, a ftate of reft and

CHRYSAETUS, in ornibutterflies, moths, and fe-

CHRYSALIS, in natcts, muft pafs through before feeming infenfibilwinged or moft perfect ftate. See veral other kiтory.

they arriнEMOIDES, in botany. See Osteo-Natум.

CHRSANTHEMUM, in botany, a genus of plants belonging to the fyngenefia polygamia fuperflua clafs. The receptacle is naked, it has no pappus; the calix is hemifpherical and imbricated; and the fcales on the margin are membranaceous. There are nineteen fpecies, two of which are natives of Britain, *viz.* the fegetum, or corn mary-gold; and the leucanthemum, or ox-eye daify.

CHRYSOBALANUS, in botany, a genus of the icofandria monogynia clafs. The corolla confifts of five petals; the calix has five teeth; and the drupa contains a nut with five furrows. There is but one fpecies, *viz.* the icaco, a native of America.

CHRYSOBERYL, a kind of beryl with a tincture of yellow. See Beryl.

CHRYSOCOLLA, in natural hiftory, a fpecies of green ochres. See Ochra.

CHRYSOCOMA, in botany, a genus of plants belonging to the fyngenefia polygamia æqualis clafs. The receptacle is naked; the pappus is fimple; the calix is imbricated and hemifpherical; and the ftylus is hardly longer than the flofcules. There are nine fpecies, none of which are natives of Britain.

CRYSOGONUM, or Moth-mullein, in botany, a genus of plants belonging to the fyngenefia polygamia neceffaria clafs. The receptacle is paleaceous; the pappus is monophyllous, and three-teethed; the calix confifts of five leaves; and the feeds are caliculated, and involved in four leaves. There is but one fpecies, a native of Virginia.

CHRYSOLITE, in natural hiftory, a gem which the ancients knew under the name of the topaz; and the true chryfolite of the ancients, which had its name from its fine gold-yellow colour, is now univerfally called topaz by modern jewellers. See Topaz.

Chrysolite-*pafte*, a kind of glafs made in imitation of natural chryfolite, by mixing two ounces of prepared cryftal, with ten ounces of red-lead, adding twelve grains of crocus martis made with vinegar; and then baking the whole for twenty-four hours, or longer, in a well luted cucurbit.

CHRYSOMELA, in zoology, a genus of infects, belonging to the order of coleoptera. The antennæ are fhaped like bracelets, and thicker on the outfide; and neither the breaft nor the elytra are marginated. There are no lefs than 127 fpecies, principally diftinguifhed by differences in their colour.

CHRYSOPHYLLUM, in botany, a genus of the pentandria monogynia clafs. The corolla is bell-fhaped, and divided into ten fegments, which alternately fpread wider; and the berry contains ten feeds. There are but two fpecies, both natives of America.

CHRYSOPRASUS, or Chrysoprasius, the tenth of the precious ftones, mentioned in the Revelations, as forming the foundation of the heavenly Jerufalem.

The chryfoprafius is a fpecies of prafius, of a pale but pure green colour, with an admixture of yellow.

CHRYSOSPLENIUM, in botany, a genus of the decandria digynia clafs. The calix is divided into four or five coloured fegments; it has no corolla; and the capfule has two beaks, and one cell containing many feeds. The fpecies are two, *viz.* the alternifolium, or alternate leaved golden faxifrage; and the oppofitifolium, or common golden faxifrage; both natives of Britain.

CHRYSTAL, or Crystal. See Crystal.

CHUB, or Chubb, in ichthyology. See Cyprinus.

CHURCH, has different fignifications, according to the different fubjects to which it is applied. 1. It is underftood of the collective body of Chriftians, or all thofe over the face of the whole earth who profefs to believe in Chrift, and acknowledge him to be the Saviour of mankind. This is what the ancient writers call the catholic or univerfal church. Sometimes the word church is confidered in a more extenfive fenfe, and divided into feveral branches; as the church militant, is the affembly of the faithful on earth; the church triumphant, that of the faithful already in glory; to which the Papifts add the church patient, which, according to their doctrines, is that of the faithful in purgatory.

2. Church is applied to any particular congregation of Chriftians, who affociate together and concur in the participation of all the inftitutions of Jefus Chrift, with their proper paftors and minifters. Thus we read of the church of Antioch, the church of Alexandria, the church of Theffalonica, and the like.

3. Church denotes a particular fect of Chriftians diftinguifhed by particular doctrines and ceremonies. In this fenfe, we fpeak of the Romifh church, the Greek church, the reformed church, the church of England, *&c.*

The Latin or weftern church, comprehends all the churches of Italy, France, Spain, Africa, the north, and all other countries whither the Romans carried their language. G. Britain, part of the Netherlands, of Germany, and of the North, have been feparated from hence ever fince the time of Henry VIII. and conftitute what we call the reformed church, and what the Romanifts call the weftern fchifm.

The Greek or eaftern church, comprehends the churches of all the countries anciently fubject to the Greek or eaftern empire, and through which their language was carried; that is, all the fpace extended from Greece to Mefopotamia and Perfia, and thence into Egypt. This church has been divided from the Roman, ever fince the time of the emperor Phocas.

The Gallican church, denotes the church of France, under the government and direction of their refpective bifhops and paftors. This church has always enjoyed certain franchifes and immunities, not as grants from popes, but as derived to her from her firft original, and which fhe has taken care never to relinquifh. Thefe liberties depend upon two maxims; the firft, that the pope

pope has no authority or right to command or order any thing either in general or in particular, in which the temporalities and civil rights of the kingdom are concerned; the second, that notwithstanding the pope's supremacy is owned in cases purely spiritual, yet, in France, his power is limited and regulated by the decrees and canons of ancient councils received in that realm.

4. The word church is used to signify the body of ecclesiastics, or the clergy, in contradistinction to the laity. See CLERGY.

5. Church is used for the place where a particular congregration or society of Christians assemble for the celebration of divine service. In this sense, churches are variously denominated, according to the rank, degree, discipline, &c. as metropolitan church, patriarchal church, cathedral church, parochial church, collegiate church, &c. See METROPOLIS, PATRIARCH, &c.

CHURCH-*reeves*, the same with church-wardens.

CHURCH-STRETTON, a market-town of Shropshire, about twelve miles south of Shrewsbury: W. long. 2° 50′, N. lat. 52° 35′.

CHURCH-*wardens*, formerly called church-reeves, are officers chosen yearly, in Easter week, by the minister and parishoners of every parish, to look after the church, church-yard, church-revenues, &c. also to observe the behaviour of the parishoners in relation to such misdemeanors as appertain to the censure or jurisdiction of the ecclesiastical court.

They are to be chosen by the joint consent of the minister and his parishoners; and by custom, the minister may chuse one, and the parishoners another; or, if there be a custom for it, the parishoners may elect both, though it is against the canon. They were sworn into their office by the archdeacon; and if he refuses to swear a church-warden, a mandamus may issue out to compel him: for as the church-wardens have a trust reposed in them by the parish, as temporal officers, the parishoners are the proper judges of their abilities to serve, and not the archdeacon who swears them.

The church wardens are a corporation to sue, and be sued, for the goods of the church: they are to take care of the repairs of the church; and if they erect or add any thing new to the same, they must have the consent of the parishoners, or vestry; and if in the church, the license of the ordinary: they have, with consent of the minister, the placing of the parishoners in the seats of the body of the church, appointing gallery keepers, &c. reserving to the ordinary a power to correct the same. In London, the church-wardens have this authority in themselves: there also they are bound to fix fire-cocks, keep engines, &c. in their parishes, under the penalty of 10l.

Besides their ordinary power, the church-wardens have the care of the benefice during its vacancy: they are to join with the overseers of the poor in making rates for their relief, setting up trades for employing them, placing out poor apprentices, settling poor persons, &c. It is their duty to collect the charity-money upon briefs read in churches; they are to sign the certificates of those persons who receive the sacrament, to qualify them to bear offices, &c.

CHURCHING *of women after child-birth*, an office in the liturgy, containing a thanksgiving to be used by women after being delivered from the great pain and peril of child-birth.

CHURN-OWL, in ornithology. See CAPRIMULGUS.

CHURN-WORM, in zoology. See GRYLLOTALPA.

CHUSAN, or CHEUXAN, an island on the eastern coast of China, near the province of Chekiam: E. long. 124°, N. lat. 30° 40′.

CHUSISTAN, a province in the south-west part of Persia, bounded by the gulph of Persia on the south, and by the province of Eyraca-Agem on the north.

CHUTON, CHUTTON, a market-town of Somersetshire, about seven miles north-east of Wells: W. long. 2° 36′, N. lat. 51° 25′.

CHYLE, in the animal œconomy, a milky fluid, secreted from the aliments by means of digestion.

The principles of the chyle seem to be sulphureous, mucilaginous, saline, and aqueous. It is a kind of natural emulsion, both with regard to the colour, the ingredients, and the manner of preparation. There is this difference between the artificial and natural emulsion, that the latter is far more pure, and is prepared with much greater apparatus, not by the sudden expression of part of the liquid, but by a gentle and successive percolation. The chyle is made sooner or later, according to the difference of the temperaments, strength, aliments and customs: therefore how many hours chylification requires, cannot be certainly determined. When the chyle enters the villous oscula of the lacteals, it is not a fluid extracted merely from the aliment and drink, but a mixture of fluids; that is, the saliva and thinner mucus of the mouth, and the two fluids of the œsophagus, one proceeding from the villous membrane of the tube itself, the other from its glands. To these may be added the glutinous fluid of the stomach, the pancreatic juice, the fluid of peyer's glands, which are very numerous in the small intestines. Hence the reason appears, why men may live upon bread and water, why the oriental nations use rice in the room of all kinds of pulse, and why acids, spirituous liquors, saline things, and many vegetable juices, herbs, roots, acrid and aromatic substances, are the least fit to generate chyle.

CHYLIFICATION, the formation of the chyle, or the act whereby the food is changed into chyle.

Chylification commences by comminuting the aliment in the mouth, mixing it with saliva, and chewing it with the teeth; by these means the food is reduced into a kind of pulp, which, being received into the stomach, mixes with the juices thereof; and thus diluted, begins to ferment or putrify, and, assuming a very different form from what it had before, grows either acid or rancid. Here it meets with a juice separated from the blood by the glands of that part, whose excretory ducts open into the cavity of the stomach:

ftomach: by the commixture of thefe liquors, whether of faliva or the juice of the ftomach, a proper menftruum is compofed, by which the parts of the aliment are ftill more and more divided by its infinuating into their pores, and acquire ftill a greater likenefs to the animal fluids. The ftomach, by means of its mufcular fibres, contracting itfelf, does gradually dicharge its contents by the pylorus into the duodenum; in which gut, after a fmall femicircular defcent, it meets with the pancreatic juice and bile; both which joining it, renders fome part of the aliment more fluid, by ftill difuniting the groffer part from the more pure, and here the chylifaction is made perfect. The bile which abounds with lixivial falts, and apt to entangle with the groffer parts of the concocted aliment, ftimulates the guts, and cleanfes their cavities of the mucous matter feparated from the blood by the glands of the guts, and lodged in their cavities; which not only moiftens the infide of the guts, but defends the mouth of the lacteal veffels from being injured by alien bodies which often pafs that way.

The contents of the inteftines move ftill on, by means of the periftaltic motion of the guts; whilft thofe thinner parts, fitted to the pores of the lacteal veffels, are abforbed by them: the thicker move ftill more flowly on, and by the many ftops they continually meet with by the connivant valves, all the chyle or thin parts are at length entirely abforbed; the remains being merely excrementitious, are only fit to be protruded by ftool.

In the paffage through the fmall inteftines, the finer part of the mafs, which we call the chyle (as has been already obferved) enters the orifices of the lacteal veffels of the firft kind, wherewith the whole mefentery is intermixed, which either alone, or together with the meferaic veins. difcharge themfelves into the glands, at the bafis of the mefentery.

Then the chyle is taken up by the lacteals of the fecond kind, and is conveyed into glands between the two tendons of the diaphragm, called Pecquet's refervatory; whence it is carried to the heart by the thoracic duct, and the fubclavian vein: and here it firft mixes with the blood, and in time becomes affimilated thereto.

CHYLOSIS, among phyficians, the act of reducing the aliment in the ftomach to chyle.

CHYME, or CHYMUS, in the common fignification of the word, denotes every kind of humour which is incraffated by concoction, under which notion it comprehends all the humours fit or unfit for preferving and nourifhing the body, whether good or bad. It frequently imports the fineft part of the chyle, when feparated from the fæces, and contained in the lacteal and thoracic duct.

CHYMISTRY, or CHEMISTRY. See CHEMISTRY.

CHYMOLOGI, an appellation given to fuch naturalifts as have employed their time in inveftigating the properties of plants from their tafte and fmell.

CHYMOSIS, in medicine, the act of making or preparing chyme. See CHYME.

CHYMOSIS is alfo a diftortion of the eye-lids, arifing from an inflammation; alfo an inflammation of the cornea tunica in the eye.

CIALIS, the name of the capital of a kingdom of that name in independant Tartary, fituated on the road from Samarcand to China.

CIBDELOPLACIA, in natural hiftory, a genus of fpars debafed by a very large admixture of earth: they are opaque, formed of thin crufts, covering vegetables and other bodies, by way of incruftations.

Of this genus we have the following fpecies: 1. A greyifh-white one, with a rough furface. 2. A whitifh brown one: both thefe are friable. 3. A hard, pale-brown kind, which is the oftecolla of the fhops. 4. The whitifh-grey kind, with a fmooth furface: this is the unicornu foffile and ceratites of authors. 5. The whitifh-brown coralloide kind.

CIBDELOSTRACIA, in natural hiftory, terrene fpars, deftitute of all brightnefs and tranfparence, formed into thin plates, and ufually found coating over the fides of fiffures, and other cavities of ftone, with congeries of them of great extent, and of plain or botroyide furfaces.

Of thefe there are ufually reckoned feven kinds: the firft is the hard, brownifh-white cibdeloftracium, found in Germany: the fecond is the hard, whitifh cibdeloftracium, with thin crufts, and a fmoother furface, found alfo in the Harts-foreft in Germany: the third is the hard, pale-brown cibdeloftracium, with numerous very thin crufts, found in fubterranean caverns in many parts of England as well as Germany: the fourth is the white, light, and friable cibdeloftracium, found alfo in Germany, but very rarely in any part of England: the fifth is the light, hard, pale-brown cibdeloftracium, with a fmooth furface, found in almoft all parts of the world: the fixth is the whitifh, friable, cruftaceous cibdeloftracium, with a rougher furface, frequent in Germany and England; and the feventh is the brownifh-white, friable cibdeloftracium, with a dufty furface, found in feveral parts of Ireland, as well as Germany.

CICADIA, in zoology, a genus of infects belonging to the order of hemiptera. The beak is inflected; the antennæ are fetaceous; the four wings are membranaceous and deflected; and the feet, in moft of the fpecies, are of the jumping kind. The fpecies are fifty-one. The larvæ of feveral of this genus evacuate great quantities of a frothy matter upon the branches and leaves of plants, in the midft of which they conftantly refide.

CICATRICULA, among natural hiftorians, denotes a fmall whitifh fpeck in the yolk of an egg, fuppofed to be the firft rudiments of the future chick.

CICATRIX, in furgery, a little feam or elevation of callous flefh rifing on the fkin, and remaining there after the healing of a wound or ulcer. It is commonly called a fcar. See SURGERY.

CICATRIZANTS, in pharmacy, medicines which affift nature to form a cicatrix. Such are arminian bole, powder of tutty, dificcativum rubrum, &c.

Cicatrizants are otherwife called efcharotics, epulotics, incarnatives, agglutinants, &c.

CICELY. See MYRRHIS.

CICER, or CHICK-PEA, in botany, a genus of the diadelphia decandria clafs. The calix is divided into five fegments, of the fame length with the corolla, the four uppermoft fegments lying upon the vexillum; and the legumen or pod is turgid, rhomboidal, and contains two feeds. There is but one fpecies, *viz.* the arietinum, a native of Spain.

CICERBITA, in botany. See SONCHUS.

CICHORIUM, or SUCCORY, in botany, a genus of the fyngenefia polygamia æqualis clafs. The receptacle is paleaceous; the calix is caliculated; and the pappus has five teeth on its margin. The fpecies are three, only one of which, *viz.* the intybus, or wild cichory, is a native of Britain. The leaves and root are detergent, aperient, and attenuating.

CICINDELIA, in zoology, a genus of infects belonging to the order of coleoptera. The antennæ are fetaceous; the jaws are prominent, and furnifhed with teeth; the eyes are a little prominent; and the breaft is roundifh and marginated. There are fourteen fpecies.

CICONIA, in ornithology. See ARDEA.

CICUTA, in botany, a genus of the pentandria digynia clafs. The fruit is furrowed and ovated. The fpecies are three, only one of which, *viz.* the virofa, or long-leaved water-hemlock, is a native of Britain.

CICUTA is alfo a fynonime of the conium. See CONIUM.

CICUTARIA, in botany, a fynonime of the æthufa, phellandrium, *&c.*

CIDARIS, in antiquity, the mitre ufed by the Jewifh high-priefts. The Rabbins fay, that the bonnet ufed by priefts in general was made of a piece of linen-cloth fixteen yards long, which covered their heads like a helmet or a turbant: and they allow no other difference between the high-prieft's bonnet, and that of other priefts, than this, that one is flatter and more in the form of a turbant; whereas that worn by ordinary priefts, rofe fomething more in a point.

CIDARIS, in conchyliology, the trivial name of a fpecies of echinus. See ECHINUS.

CIFALU, or CEFALEDI, a port-town of Sicily, thirty-fix miles eaft of Palermo: E. long. 13° 32′, N. lat. 38° 30′.

CILIA, the EYE-LASHES, in anatomy. See Vol. I. p. 291.

CILIARE, or LIGAMENTUM CILIARE, in anatomy. See Vol. I. p. 290.

CILIARIS, in anatomy. See Vol. I. p. 291.

CILIATED *leaf*, among botanical writers, one furrounded all the way with parallel filaments, fomewhat like the hairs of the eye-lids.

CILICIUM, in Hebrew antiquity, a fort of habit made of coarfe ftuff, formerly in ufe among the Jews in times of mourning and diftrefs. It is the fame with what the Septuagint and Hebrew verfions call fack-cloth.

CILLEY, the capital of a territory of the fame name in Stiria, and the circle of Auftria in Germany: E. lon. 15° 35′, N. lat. 46° 35′.

CIMA, or SIMA, in architecture, the fame with cymatium or ogee. See OGEE.

CIMEX, or BUG, in zoology, a genus of infects belonging to the order of hemiptera. Linnæus enumerates no lefs than 121 fpecies. The lectularius, or common houfe-bug, is a well known infect. The methods of expelling them are various; as, oil of turpentine, the fmoke of corn-mint, of narrow-leaved wild-crefs, of herb-robert, of the reddifh agaric, of muftard, of Guiney pepper, of peats or turf, *&c.* But cleanlinefs is the only remedy againft vermin of every kind.

CIMOLIA *terra*, in natural hiftory, a fpecies of white marle, which is ponderous and friable, and makes a confiderable effervefcence with aqua fortis.

CINALOA, a province of Mexico, in North America, lying on the Pacific Ocean, oppofite to the fouth end of California.

CINAN, a city of China, the metropolis of the province of Zantung, fituated in 37° N. lat. and 30′ eaft of Pekin.

CINCHONA, in botany, a genus of the pentandria monogynia clafs. The corolla is bell-fhaped; and the capfule is below the flower, and opens at the bafe. There is but one fpecies, *viz.* the officinalis, a native of Peru. The Peruvian bark, which is the bark of this tree, is brought to us in pieces of different fizes, fometimes rolled up into fhort thick quills, and fometimes flat: the outfide is brownifh, and generally covered in part with a whitifh mofs; the infide is of a yellowifh, reddifh, or rufty iron colour. It has a lightly aromatic fmell, fomewhat mufty, yet not difagreeable; a bitterifh, aftringent tafte, which dwells long upon the tongue, accompanied with a degree of aromatic warmth. The fmall, thin, flat pieces are by fome accounted the beft; by others, the quill fort, with the roughest coat, efpecially if of a bright cinnamon colour on the infide; though the large flat pieces, whether rough or fmooth, of a lighter or darker colour, are often of equal goodnefs. The beft bark is that which is ftrongeft in fmell and tafte: this likewife proves friable betwixt the teeth, and does not feparate into fibres; it breaks, not fhivery, but clofe and fmooth.

The virtues of this bark, as a febrifuge, were difcovered by the Indians about the year 1500: Europe did not become acquainted with it till 1649: nor was it received into general practice till feveral years after this; fome ill confequences enfuing from its imprudent ufe, having brought it for a time into difrepute. At prefent, it is looked upon as the moft effectual remedy in intermittent fevers of almoft every kind, and fafe in all ages and conftitutions; provided it be judicioufly and feafonably adminiftered, and due regard be had to the circumftances of the difeafe. The modern practice, previous to the ufe of this medicine, ufually gives an emetic at the beginning of a paroxyfm: in fome cafes a cathartic, and in plethoric habits venæfection, are premifed: thefe render the bark not only more fafe, but likewife more certain and fpeedy in its operation: where thefe evacuations are neglected, or not fufficiently plentiful, the difeafe, if of long ftanding,

ftanding, fcarce yields to the *cortex*; or if it appears at length fubdued, yet the patient does not recover his ftrength, and foon fuffers a relapfe. The ufe of the bark is begun at the end of a paroxyfm, and repeated, in the quantity of half a dram (more or lefs, according to the circumftances of the patient) every third or fourth hour during the intermiffion: where the fever is of the bilious kind, and accompanied with great heat, a little nitre is joined: in all cafes, moderate exercife generally promotes its effect. At firft, it ufually loofens the belly, and fometimes operates as if a cathartic had been taken; and by this means fupplies the omiffion of evacuations before its exhibition: if the purging continues, the medicine does not anfwer the purpofes intended by it: in fuch cafe, a little opium is added, which effectually fuppreffes the flux: if after this the patient continues too coftive, recourfe is had to glyfters. The loofenefs, however, ought not to be ftopt too foon: on the contrary, where the bark does not itfelf produce this effect, it is neceffary, as Dr Mead informs us, to join to it a little rhubarb, fo as to occafion for a time two ftools a day; by this means the difeafe is more effectually cured, and lefs fubject to be followed by a dropfy, or ill habit of body; after a dram or two of rhubarb have been taken, it is to be difcontinued, and the bark exhibited by itfelf. After the fever has been removed, the medicine is continued for fome time longer, to prevent a relapfe; and evacuations, unlefs abfolutely neceffary, abftained from. The difeafe is neverthelefs feldom completely cured before fome very confiderable evacuation, either by ftool, urine, or perfpiration, enfues: if this does not fucceed fpontaneoufly, cathartics, diuretics, or diaphoretics, are given in conjunction with the bark; otherwife the patient continues weak, and without appetite, till either the difeafe returns, or changes into one of a different kind.

In fymptomatic agues, hectic and purulent fevers, cacochymic habits, and where the hypochondres are fwelled and diftended, this medicine is improper, and for the moft part prejudicial. Its manifeft aftringency forbids its ufe in obftructions of the abdominal vifcera, or fuppreffion of any critical evacuation; until the obftruction is firft removed, or the evacuation had its due courfe.

In acute, inflammatory, or malignant fevers, the bark does not feem to have any good effect. Neverthelefs, in the decline of long nervous fevers, or after a remiffion, when from bad habit, old age, fatigue, or the like, the patient is extremely weak, and the pulfe low, the *cortex* proves a medicine of excellent fervice; provided that there is no extravafation, that the veffels remain entire, and pus is not already formed.

Peruvian bark has likewife been found eminently ferviceable in gangrenes and mortifications, proceeding either from an internal or external caufe. In all the cafes of this kind, where it proved fuccefsful, it occafioned a kind fuppuration, which degenerated when the ufe of the medicine was difcontinued, and again turned kindly upon refuming it. Some have been hence induced to try the *cortex* in variolous cafes, where either the puftules did not rightly fuppurate, or petechiæ fhewed a difpofition to a gangrene; and here likewife it anfwered expectation: the empty veficles filled with matter, watery fanies changed into thick white pus, the petechiæ became gradually of a pale colour, and at length difappeared, and the pox began to turn fooner than was expected.

The bark has been applied likewife, and not without fuccefs, to the cure of periodic head-achs, hyfteric and hypochondriac fits, and other diforders, which have regular intermiffions. By its aftringency and aromatic quality, it ftrengthens the whole nervous fyftem, and proves ufeful in weaknefs of the ftomach, and fundry chronical diforders, proceeding from too great laxity of the fibres. In obftinate uterine fluxes, and old gleets, bark joined with chalybeates has notable effects.

The virtues of Peruvian bark refide chiefly in a refinous fubftance, and hence are extracted in perfection by rectified fpirit. By ftrong coction in water, the refin is melted out, and mingled with the water; which whilft hot appears tranfparent, but in cooling grows turbid, and depofites great part of the refin to the bottom. Water elevates in diftillation the aromatic part of the bark; pure fpirit brings over nothing. Hence an aqueous extract proves not only lefs in quantity, but likewife inferior in quality to one made with rectified fpirit. Proof-fpirit extracts the virtues of this drug in tolerable perfection, in the cold; heat enables it to take up more than it can retain when cold. Spirit of fal ammoniac, prepared with fixt alkaline falts, gains very little from the *cortex*, either with or without heat: the fpirit prepared with quicklime, and the dulcified fpirit, in a few hours become ftrongly impregnated with its fmell and tafte.

The officinal preparations of bark are an extract refin, fpirituous tincture, tincture in volatile fpirit, and compound tincture. It is an ingredient alfo in the ftomachic tincture.

The fubftances ufually joined with bark in prefcription feem calculated either to promote its efficacy, or merely for reducing it into the intended form; without much regard to its agreeablenefs, and the conveniency of taking it: this is neverthelefs a point of great confequence, as its tafte, and the quantity which is neceffary, make the patient too frequently loath it, before enough has been taken to produce the defired effect. If defigned to be given in the folid form of a bolus, electuary, *&c.* it fhould be made up, not, as is cuftomary, with fyrups, but with mucilages: with the former, it fticks about the mouth and fauces, whence its tafte remains for a confiderable time; with the latter, it paffes freely, fcarce leaving any tafte in the mouth. Aromatics do not prevent the tafte of the bark from difcovering itfelf; extract of liquorice very effectually conceals it. The extract of logwood alfo, joined to that of bark, and a proper quantity of mucilage, form a very elegant and agreeable compofition.

CINCLUS, in ornithology. See TRINGA.

CINCTURE,

CINCTURE, or CEINTURE, in architecture, a ring, lift, or orlo at the top and bottom of the shaft of a column, separating the shaft at one end from the base, and at the other from the capital. See ARCHITECTURE.

CINERARIA, in ornithology. See MOTACILLA.

CINNABAR, in natural history, is either native or factitious. The native cinnabar is an ore of quick-silver, moderately compact, very heavy, and of an elegant, striated red colour. In this ore the quick-silver is blended in different proportions with sulphur. It is so rich an ore, as to be no other than mercury impregnated with a small quantity of sulphur, just enough to reduce it to that state, being commonly more than six parts of mercury to one of sulphur; and even the poorest cinnabar yields one half mercury: it is of a very bright, glittering appearance, when fresh broken, and is usually found lodged in a bluish, indurated clay, though sometimes in a greenish talcy stone.

For the method of separating mercury from cinnabar, see MERCURY.

Factitious CINNABAR, a mixture of mercury and sulphur sublimed, and thus reduced into a fine red glebe. The best is of a high colour, and full of fibres, like needles.

The receipt for making it, according to the late college-dispensatory, is as follows. Take of purified quick-silver, twenty-five ounces; of sulphur, seven ounces; melt the sulphur, and stir the quick-silver into it while fluid; if it take fire, let it be immediately extinguished, by covering it with another vessel. When cold, let it be rubbed into a fine powder. Let this powder be put into a subliming vessel, and setting it over a gentle fire, raise it by degrees till the whole is sublimed into a red, striated, heavy mass, which perfectly resembles native cinnabar. This, as well as the native cinnabar, is excellent in epilepsies, and in all complaints of the head and nerves. But the factitious is rather to be preferred, as it doth not excite nauseas, vomitings, and other disorders which arise from vitriolic and perhaps arsenical particles blended by nature among some of the masses of the native mineral.

Cinnabar is likewise used by painters as a colour, and is rendered more beautiful, by grinding it with gum-water and a little saffron.

CINNAMON-TREE, in botany. See LAURUS.

CINNAMON-WATER is made by distilling the bark first infused in spirit of wine, brandy, or white-wine.

Clove-CINNAMON is the bark of a tree growing in Brazil, which is often substituted for real cloves.

White CINNAMON, called also Winter's bark, is the bark of a tree frequent in the islands of St Domingo, Guadalupe, *&c.* of a sharp biting taste like pepper. Some use it instead of nutmeg; and in medicine it is esteemed a stomachic and antiscorbutic.

CINOLOA, or CINALOA, the capital of the province of Cinaloa, in North America, about thirty miles east of the bay of California: W. long. 113°, and N. lat. 25°. See CINALOA.

CINQUEFOIL, *quinquefolium*, in botany. See POTENTILLA.

CINQUE-PORTS, an appellation given to five port-towns, situated on the coast of Kent and Sussex, over-against France, and famous in English history.

The cinque-ports are Hastings, Dover, Hithe, Romney, and Sandwich; which have had large privileges granted them, on account of their former great importance, being then not only the keys of the kingdom, but considerable for their maritime strength: thus, we are told, that they were obliged to provide eighty ships at their own charge for forty days, as often as the king should have occasion in his wars.

CINQUE-PORT is also a particular kind of fishing-net much used in standing water, so called on account of the five entrances into it.

CINTRA, a cape and mountain of Portugal, in the province of Estremadura, usually called the rock of Lisbon, situated on the north side of the entrance of the river Tagus: W. long. 10° 15′, N. lat. 39°.

CINYRA, or CINNOR, in Jewish antiquity, generally translated cithara, lyra, *&c.* a musical instrument used before the flood, and invented by Jubah the son of Lamech.

CION, or CYON, among gardeners, denotes a young sprig, or sprout of a tree.

CIPHER, or CYPHER, one of the Arabic characters, or figures, used in computation, formed thus, 0. See ARITHMETIC.

CIPHER is also a kind of enigmatic character, composed of several letters interwoven, which are generally the initial letters of the persons names for whom the ciphers are intended.

CIPHER denotes likewise certain secret characters disguised and varied, used in writing letters that contain some secret, not to be understood but by those between whom the cipher is agreed on.

CIPPUS, in antiquity, a low column, with an inscription, erected on the high roads, or other places, to shew the way to travellers, to serve as a boundary, to mark the grave of a deceased person, *&c.*

CIRCÆA, or ENCHANTERS NIGHTSHADE, in botany, a genus of the diandria monogynia class. The corolla consists of two petals; the corolla has likewise two leaves; and the capsule contains but one seed. The species are three, two of which are natives of Britain, *viz.* the lutitiana, or enchanters-nightshade; and the alpina, or mountain enchanters-nightshade.

CIRCASSIA, a country situated between 40° and 50° E. long. and between 45° and 50° N. lat.

It is bounded by Russia on the north, by Astracan and the Caspian sea on the east, by Georgia and Dagestan on the south, and by the river Don and the Palus Meotis on the west.

The Circassian Tartars form a kind of republic, but sometimes put themselves under the protection of Persia, and sometimes of Russia, or the Turks. They live mostly in tents, removing from place to place for the benefit of pasturage; and are chiefly remarkable for the beauty of their children, the seraglios of Turky and

and Persia being usually supplied with boys and young virgins from this and the neighbouring country of Georgia.

CIRCENSIAN GAMES, a general term under which was comprehended all combats exhibited in the Roman circus, in imitation of the Olympic games in Greece. Most of the feasts of the Romans were accompanied with Circensian games; and the magistrates, and other officers of the republic, frequently presented the people with them, in order to procure their favour. The grand games were held five days, commencing on the 15th of September. There were six kinds of games exhibited: the first was wrestling, and fighting with swords, with staves, and with pikes; the second was racing; the third, leaping; the fourth, quoits, arrows, and cestus; all which were on foot; the fifth was horse-coursing: the sixth courses of chariots.

CIRCIA, in ornithology, a species of anas, called in english the summer-teal, and all over of a dusky yellowish brown, with black feet.

CIRCINALIS, in botany, a name used by some for adiantum, maiden-hair. See ADIANTUM.

CIRCLE, in geometry, a plane figure comprehendred by a single curve line, called its circumference, to which right lines drawn from a point in the middle, called the centre, are equal to each other. To find the area of a circle, see PRACTICAL GEOMETRY.

CIRCLES *of the sphere*. See GEOGRAPHY and ASTRONOMY.

CIRCLES *of latitude*. See GEOGRAPHY.

CIRCLES *of longitude*. See GEOGRAPHY.

Horary CIRCLES, in dialling, are the lines which shew the hours on dials, though these be not drawn circular, but nearly streight. See DIALLING.

Horary CIRCLE, on the globe. See GEOGRAPHY.

Polar CIRCLE. See GEOGRAPHY.

CIRCLE, in logic, or *logical* CIRCLE, is when the same terms are proved *in orbem* by the same terms; and the parts of the syllogism alternately by each other, both directly and indirectly.

CIRCLES *of the empire*, such provinces and principalities of the German empire as have a right to be present at diets. Maximilian I. divided the empire into six, and some years after into ten circles. This last division was confirmed by Charles V. The circles, as they stand in the Imperial Matricola, are as follows, Austria, Burgundy, the Lower Rhine, Bavaria, Upper Saxony, Franconia, Swabia, Upper Rhine, Westphalia, and the Lower Saxony.

CIRCOLO MEZZO, in the Italian music, denotes a diminution of four quavers or semiquavers, which represent a semicircle, proceeding by conjoint degrees.

CIRCUIT, in law, signifies a longer course of proceedings than is needful to recover the thing sued for.

CIRCUIT, also signifies the journey, or progress, which the judgestake twice every year, through the several counties of England and Wales, to hold courts and administerjustice, where recourse cannot be had to the king's courts at Westminster: hence England is divided into six circuits, *viz.* the Home circuit, Norfolk circuit, Midland circuit, Oxford circuit, Western circuit, and Northern circuit.

In Wales there are but two circuits, North and South Wales: two judges are assigned by the king's commission to every circuit.

CIRCUIT *court*, in Scots law, the judges of the supreme criminal court, or court of justiciary, are divided into three separate courts, consisting of two judges each; and the kingdom into as many districts. In certain boroughs of every district, each of these courts by rotation are obliged to hold two courts in the year, in spring and autumn; which are called circuit courts. See SCOTS LAW, *Of the supreme judges and courts of Scotland*.

CIRCULAR, in a general sense, any thing that is described or moved in a round, as the circumference of a circle, or surface of a globe.

CIRCULAR NUMBERS, called also spherical ones, according to some, are such whose powers terminate in the roots themselves.

Thus, for instance, 5 and 6, all whose powers do end in 5 and 6, as the square of 5 is 25, the square of 6 is 36, *&c.*

CIRCULAR SAILING is the method of sailing by the arch of a great circle. See NAVIGATION.

CIRCULATION, the act of moving round, or in a circle: thus we say, the circulation of the blood, *&c.*

CIRCULATION *of the blood*, the natural motion of the blood in a living animal, whereby that fluid is alternately carried from the heart into all parts of the body, by the arteries, from whence it is brought back to the heart again by the veins.

This motion is chiefly caused by the the dilatation and contraction of this organ, and is the principle on which life depends; for when it ceases in any part, it dies; when it is diminished, the operations are weak; and, when it ceases totally, life is extinguished.

All the veins discharge themselves into the ventricles of the heart; from hence all the arteries arise: the blood expelled out of the right ventricle must be carried, through the pulmonary artery, into the lungs; from which it must be returned, by the pulmonary veins, to the left ventricle; from the left ventricle the blood, thus imported, is, by the constriction of that part, again expelled into the aorta, and by it distributed all over the rest of the body, and thence is returned again to the right ventricle by the cava, which completes the circulation.

This circulation becomes actually visible, with the assistance of a microscope, especially in fish, frogs, *&c.* wherein the inosculation, or union of the extremities of the arteries with those of the veins, together with the globules of the blood flowing from the one into the other, may be plainly seen.

The auricles of the heart being large hollow muscles, furnished with a double series of strong fibres, proceeding with a contrary direction to the opposite tendons, the one adhering to the right ventricle, the other to the sinus venosus; as also with innumerable

veins and arteries; by the contractile force of these auricles, the blood will be vigorously expressed and driven into the right ventricle, which, upon this contraction, is rendered flaccid, empty, and disposed to admit it.

Now, if the right ventricle, thus full of blood, by the contraction of its fibres, press the blood towards the aperture again, the venous blood at the same time pouring in, will drive it back again into the cavity, and mix it more intimately, till, rising up against the parietes, it raise the valvulæ tricuspides, which are so connected to the fleshy columns extended on the opposite side, as that, when laid quite down, they cannot close the parietes of the right ventricle; these it thrusts towards the right auricle, till being there joined, they stop the passage very closely, and prevent any return.

By the same means, the same blood rises into the three semilunar valves, placed in the extremity of the other mouth, and lying open to the pulmonary artery; these it shuts close against the sides of the artery, and leaves a passage into the artery alone: the blood carried by this artery into the lungs, and distributed by its branches through the whole substance thereof, is first admitted into the extremities of the pulmonary vein, called arteria venosa; whence passing into four large vessels, which unite together, it is brought to the left sinus venosus, or trunk of the pulmonary vein, by the force of whose musculous structure it is driven into the left ventricle, which, on this occasion, is relaxed, and by that means prepared to receive it.

Hence, as before, it is driven into the left ventricle, which is relaxed by the same means; and by the valvulæ mitrales opening, admit it into the left ventricle, and hinder its flux into the pulmonary vein: from hence it is forced into the aorta, at whose orifice there are three semilunar valves, which also prevent a reflux, by closing the same.

The motion of the blood in living animals is attended with the following phenomena: 1. Both the venous sinuses are filled, and grow turgid at the same time. 2. Both auricles grow flaccid at the same time, and both are filled at the same time with blood, impelled by the contractile force of its correspondent muscular venous sinus. 3. Each ventricle contracts and empties itself of blood at the same time; and the two great arteries are filled and dilated at the same time. 4. As soon as the blood, by this contraction, is expelled, both ventricles being empty, the heart grows larger and broader. 5. Upon which the muscular fibres of both venous sinuses contract, and express the blood contained in them into the ventricle of the heart. 6. In the mean time the venous sinuses are again filled as before, and the auricles, *&c.* return into their former habitude. 7. This alteration continues till the animal begins to languish under the approach of death, at which time the auricles and venous sinuses make several palpitations, for one contraction of the ventricle.

In a fœtus, the apparatus for the circulation of the blood is somewhat different from that in adults. The septum, which separates the two auricles of the heart, is pierced through with an aperture, called the foramen ovale, and the trunk of the pulmonary artery, a little after it has left the heart, sends out a tube into the descending aorta, called the communicating canal. The fœtus being born, the foramen ovale closes by degrees, and the canal of communication dries up, and becomes a simple ligament.

As to the velocity of the circulating blood, and the time wherein the circulation is completed, several computations have been made. By Dr Keil's account, the blood is driven out of the heart into the aorta with a velocity which would carry it twenty-five feet in a minute: but this velocity is continually abated in the progress of the blood, in the numerous sections or branches of the arteries, so that before it arrive at the extremities of the body, its motion is greatly diminished. The space of time wherein the whole mass of blood ordinarily circulates, is variously determined. Some state it thus: Supposing the heart to make two thousand pulses in an hour, and that at every pulse there is expelled an ounce of blood; as the whole mass of blood is not ordinarily computed to exceed twenty-four pounds, it must be circulated seven or eight times over in the space of an hour.

The circulation of the blood was first discovered in England, in the year 1728, by Dr Harvey.

CIRCULATION *of the sap of vegetables*. See Vol. I. p. 45.

CIRCULATION, in chemistry, is an operation whereby the same vapour, raised by fire, falls back, to be returned and distilled several times.

CIRCULATION *of money*. See COMMERCE, and MONEY.

CIRCULUS, in chemistry, an iron instrument in form of a ring, which being heated red hot, and applied to the necks of retorts and other glass vessels, till they grow hot, a few drops of cold water thrown upon them, or a cold blast, will make the necks fly regularly and evenly off.

Another method of doing this, is to tie a thread, first dipt in oil of turpentine, round the place where you would have it break; and then setting fire to the thread, and afterwards sprinkling the place with cold water, the glass will crack exactly where the thread was tied.

CIRCUMAJENTES MUSCULI, or OBLIQUI MUSCULI, in anatomy. See Vol. I. p. 290.

CIRCUMAMBIENT, an appellation given to a thing that surrounds another on all sides; chiefly used in speaking of the air.

CIRCUMCISION, the act of cutting off the prepuce; a ceremony in the Jewish and Mahommetan religions, wherein they cut off the foreskin of their males, who are to profess the one or the other law.

Among the Jews, the time for performing this rite was the eighth day, that is, six full days after the child was born: the law of Moses ordained nothing with respect to the person by whom, the instrument with which, or the manner how, the ceremony was to be performed; the instrument was generally a knife of stone. The child is usually circumcised at home, where the father, or godfather, holds him in his arms, while the operator takes

takes hold of the prepuce with one hand, and with the other cuts it off; a third person holds a porringer, with sand in it, to catch the blood; then the operator applies his mouth to the part, and having sucked the blood, spits it into a bowl of wine, and throws a styptic powder upon the wound. This ceremony was usually accompanied with great rejoicings and feasting, and it was at this time that the child was named in presence of the company. The Jews invented several superstitious customs at this ceremony, such as placing three stools, one for the circumcisor, the second for the person who holds the child, and the third for Elijah, who, they say, assists invisibly at the ceremony, *&c.*

The Jews distinguished their proselytes into two sorts, according as they became circumcised, or not: those who submitted to this rite were looked upon as children of Abraham, and obliged to keep the laws of Moses; the uncircumcised were only bound to observe the precepts of Noah, and were called noachidæ.

This ceremony, however, was not confined to the Jews: Herodotus and Philo Judæus observe, that it obtained also among the Egyptians and Ethiopians. Herodotus says, that the custom was very ancient among each people, so that there was no determining which of them borrowed it from the other. The same historian relates, that the inhabitants of Colchis also used circumcision; whence he concludes, that they were originally Egyptians.

The Turks never circumcise till the seventh or eighth year, as having no notion of its being necessary to salvation. The Persians circumcise their boys at thirteen, and their girls from nine to fifteen. Those of Madagascar cut the flesh at three several times; and the most zealous of the relations present, catches hold of the preputium, and swallows it.

Circumcision is practised on women by cutting off the foreskin of the clitoris, which bears a near resemblance and analogy to the preputium of the male penis. We are told that the Egyptian captive women were circumcised; and also the subjects of Prester John.

Circumcision is also the name of a feast, celebrated on the first of January, in commemoration of the circumcision of our Saviour.

CIRCUMDUCTION, in Scots law. When parties in a suit are allowed a proof of addigeamus after the time limited by the judge for taking that proof is elapsed, either party may apply for circumduction of the time of proving; the effect of which is, that no proof can afterwards be brought, and the course must be determined as it stood when circumduction was obtained. See Scots Law, title *Pobation.*

CIRCUMFERENCE, in a general sense, denotes the line or lines bounding a plane figure. However, it is generally used in a more limited sense, for the curve line which bounds a circle, and otherwise called a periphery; the boundary of a right-lined figure being expressed by the term perimeter.

CIRCUMFERENTOR, an instrument used by surveyors, for taking angles. See Practical Geometry.

CIRCUMFLEX, in grammar, one of the accents. See Accent.

CIRCUMGYRATION, denotes the whirling motion of any body round a center: such is that of the planets round the sun.

CIRCUMLOCUTION, a paraphrastical method of expressing one's thoughts, or saying that in many words which might have been said in few.

CIRCUMPOLAR *stars*, an appellation given to those stars, which by reason of their vicinity to the pole move round it without setting.

CIRCUMSCRIBED, in geometry, is said of a figure which is drawn round another figure, so that all its sides or planes touch the inscribed figure.

CIRCUMSCRIPTION, in natural philosophy, the termination, bounds, or limits of any natural body.

CIRCUMSTANCE, a particularity which, though not essential to any action, yet doth some way effect it.

CIRCUMSTANTIBUS, in law, a term used for supplying and making up the number of jurors (in case any impanelled appear not, or appearing are challenged by any party) by adding to them so many of the persons present as will make up the number, in case they are properly qualified.

CIRCUMVALLATION, or *line of* Circumvallation, in the art of war, is a trench bordered with a parapet, thrown up quite round the besieger's camp, by way of security against any army that may attempt to relieve the place, as well as to prevent desertion.

CIRCUMVOLUTION, in architecture, denotes the torus of the spiral line of the ionic volute.

CIRCUS, in antiquity, a great building of a round or oval figure, erected by the ancients, to exhibit shews to the people.

The Roman circus was a large oblong edifice, arched at one end, encompassed with porticoes, and furnished with two rows of seats, placed ascending over each other. In the middle was a kind of foot-bank, or eminence, with obelisks, statues, and posts at each end. This served them for the courses of their bigæ and quadrigæ.

Those that have measured the circus say, that it was 2187 feet long, and 960 broad; so that it was the greatest building in Rome: some say it would contain 150,000 people, others 260,000, or 300,000.

Circus, in zoology, See Falco.

CIRENCESTER, a borough-town of Gloucestershire, situated on the river Churn, fifteen miles south-east of Gloucester: W. long. 2°, noth lat. 51° 42′ It sends two members to parliament.

CIRLUS, in ornithology. See Emberiza.

CIRRI, among botanists, fine strings or thread-like filaments, by which some plants fasten themselves to walls, trees, *&c.* such are those of ivy.

Cirri, in ichthyology, certain oblong and soft appendages, not unlike little worms, hanging from the under jaws or mouths of some fishes: these cirri, commonly translated *beards*, afford marks to distinguish the different species of the fishes on which they are found.

CIRSIUM, in botany. See Serratula.

CIRSOCELE,

CIRSOCELE, a ſpecies of hernia. See MEDICINE and SURGERY.

CISALPINE, any thing on this ſide the Alps. Thus the Romans divided Gaul into ciſalpine and tranſalpine.

CISLEU, in Hebrew chronology, the ninth month of their eccleſiaſtical, and the third of the civil year, anſwering nearly to our November.

CISMAR, a town of lower Saxony, in Germany, at a little diſtance from the Baltic ſea.

CISSAMPELOS, in botany, a genus of the diœcia monadelphia claſs. The calix of the male has four leaves; the corolla is wanting; the nectarium is rotated; and the ſtamina are four connected together. The calix of the female conſiſts of one ligulated roundiſh-leaf; it has no corolla; the ſtyli are three; and the fruit is a berry containing one ſeed. There are three ſpecies, all natives of America

CISSOID, in geometry, a curve of the ſecond order, firſt invented by Diocles, whence it is called the ciſſoid of Diocles. See FLUXIONS.

CISSUS, in botany, a genus of the tetrandria monogynia claſs. The berry contains but one ſeed, and is ſurrounded by the corolla and calix, which are both divided into four ſegments. The ſpecies are five, all natives of the Indies.

CISTERCIANS, in church-hiſtory, a religious order founded in the eleventh century by St Robert, a benedictine. They became ſo powerful, that they governed almoſt all Europe, both in ſpirituals and temporals. Cardinal de Vitri deſcribing their obſervances, ſays, they neither wore ſkins nor ſhirts; nor ever eat fleſh, except in ſickneſs; and abſtained from fiſh, eggs, milk, and cheeſe: they lay upon ſtraw-beds, in their tunics and cowls: they roſe at midnight to prayers: they ſpent the day in labour, reading and prayer: and in all their exerciſes obſerved a continual ſilence. The habit of the Ciſtercian monks is a white robe, in the nature of a caſſock, with a black ſcapulary and hood, and is girt with a wooden girdle. The nuns wear a white tunic, and a black ſcapulary and girdle.

CISTERN, denotes a ſubterraneous reſervoir of rain-water; or a veſſel ſerving as a receptacle for rain or other water, for the neceſſary uſes of a family.

There are likewiſe lead-ciſterns, jar-ciſterns, *&c.* See PLUMBERY and JAR.

Authors mention a ciſtern of Conſtantinople, the vaults of which are ſupported by two rows of pillars, 212 in each row, each pillar being two feet in diameter. They are planted circularly, and in radii tending to that of the center.

CISTUS, in botany, a genus of the polyandria monogynia claſs. The corolla conſiſts of five petals, and the calix of five leaves, two of them being leſs than the other two. The ſpecies are 37, and only five of them natives of Britain, *viz.* the guttulus, or annual ciſtus; the helianthemum, or dwarf ciſtus, or ſun-flower; the ſurreianus, or narrow-leaved ciſtus; the polii-folius, or mountain dwarf ciſtus; and the hirſutus, or hoary dwarf ciſtus.

CITADEL, a place fortified with four, five, or ſix baſtions, built on a convenient ground near a city, that it may command it in caſe of a rebellion.

CITATION, in eccleſiaſtical courts, is the ſame with ſummons in civil courts. See SUMMONS.

CITATION is alſo a quotation of ſome law, authority, or paſſage of a book.

CITHARA, in antiquity, a muſical inſtrument, the preciſe ſtructure of which is not known; ſome think it reſembled the Greek delta Δ; and others, the ſhape of a half moon. At firſt it had only three ſtrings, but the number was at different times increaſed to eight, to nine, and laſtly to twenty-four. It was uſed in entertainments and private houſes, and played upon with a plectrum or quill, like the lyre.

CITHAREXYLON, in botany, a genus of the didynamia angioſpermia claſs. The calix is bell-ſhaped, and has five teeth; the corolla is tunnel ſhaped; and the berry contains two ſeeds. There are two ſpecies, both natives of America.

CITHARISTA, or CITHAROEDUS, one who played on the cithara.

CITILLE, in zoology, the trivial name of a ſpecies of mus. See MUS.

CITIZEN, a native or inhabitant of a city, veſted with the freedom and liberties of it.

A citizen of Rome was diſtinguiſhed from a ſtranger, becauſe he belonged to no certain commonwealth ſubject to the Romans. A citizen is either by birth or election; and ſons may derive the right from their fathers. To make a good Roman citizen, it was neceſſary to be an inhabitant of Rome, to be inrolled in one of the tribes, and to be capable of dignities. Thoſe to whom were granted the rights and privileges of Roman citizens, were only honorary citizens. It was not lawful to ſcourge a citizen of Rome.

CITRINELLA, in ornithology. See EMBERIZA.

CITRINUS, in natural hiſtory, a kind of ſprig cryſtal, of a fine yellow colour, which being ſet in rings is often miſtaken for a topaz.

CITRON TREE, in botany. See CITRUS.

CITRULLUS, in botany. See CUCURBITA.

CITRUS, in botany, a genus of the polyadelphia icoſandria claſs. The calix is divided into five ſegments; the petals are five, and oblong; and the fruit is a berry, conſiſting of nine cells. The ſpecies are three, *viz.* the medica, or lemon-tree, a native of Aſia; the aurantium, or orange-tree, a native of the Indies; and the trifoliata, a native of Japan.

CITTADELLA, the capital of the iſland of Minorca, about twenty-three miles weſt of Port-mahon: E. long. 3° 30′, N. lat. 40°.

CITTADELLAPIEVE, a town of Italy, in the territories of the pope, near the lake of Peruſa.

CIVENCHEU, a city of China, the ſecond metropolis of the province of Fokien, in 25° N. lat. and 2° 9′ eaſt of Pekin.

CIVES, the Engliſh name of a ſpecies of onion, growing in tufts, and ſeldom exceeding ſix inches in height: they never produce any bulbs, and are much uſed in ſallads in ſpring.

CIVET, a ſoft unctuous matter produced in the manner

of

of musk, in bags growing from the lower part of the belly of a civet-cat. See CASTOR.

CIVET-CAT, the English name of the animal which produces the civet. See CASTOR.

CIVIC CROWN, was a crown given by the ancient Romans to any soldier who had saved the life of a citizen in any engagement.

CIVIDAD *de las Palmas*, the capital of all the Canary islands, situated in the island of Canary.

CIVIDAD-REAL, a city of Spain, in the province of New Castile: it is the capital of La Mancha, situated on the river Guadiana, sixty miles south of Toledo: W. long. 4° 20′, N. lat. 39°.

CIVIL, in a general sense, something that regards the policy, public good, or peace of the citizens, or subjects of the state; in which sense we say, civil government, civil law, civil right, civil war, *&c.*

CIVIL, in a legal sense, is also applied to the ordinary procedure in an action, relating to some pecuniary matter or interest, in which sense it is opposed to criminal.

CIVIL DEATH, any thing that cuts off a man from civil society, as a condemnation to the gallies, perpetual banishment, condemnation to death, outlawry, and excommunication.

CIVIL LAW, is properly the peculiar law of each state, country, or city: but what we usually mean by the civil law, is a body of laws composed out of the best Roman and Grecian laws, compiled from the laws of nature and nations, and, for the most part, received and observed throughout all the Roman dominions for above 1200 years. See LAW.

CIVIL WAR, a war between people of the same state, or the citizens of the same city.

CIVIL YEAR is the legal year, or annual account of time, which every government appoints to be used within its own dominions, and is so called in contradistinction to the natural year, which is measured exactly by the revolution of the heavenly bodies.

CIVILIAN, in general, denotes something belonging to the civil law; but more especially the doctors and professors thereof are called civilians.

CIVITA-CASTELLANA, a city of Italy, in St Peter's patrimony, situated near the river Tiber, twenty-five miles north of Rome: E. long. 13°, N. lat. 42° 15′.

CIVITA VECCHIA, a port-town and fortress of Italy, in St Peter's patrimony, situated on a bay of the Mediterranean, thirty miles north-west of Rome: E. long. 12° 30′, N. lat. 42°.

It is the station of the galleys belonging to the pope, who has lately declared it a free port.

CLACK, among country-men. To clack wool, is to cut off the sheep's mark, which makes the weight less, and yields less custom to the king.

CLACKMANNAN, the capital of Clackmannanshire, in Scotland, situated on the northern shore of the Forth, about twenty five miles north-west of Edinburgh: W. long. 3° 40′, N. lat. 56° 15′.

The county of Clackmannan is joined with that of Kinross, which each in their turn chuse a member to represent them in parliament.

CLAGENFURT, or CLAGENFORT, the capital of Carinthia, in the circle of Austria in Germany, 120 miles south-west of Vienna: E. long. 14°, N. lat. 47°.

CLAIM, in law, a challenge of interest in any thing that is in possession of another.

CLAKIS, in ornithology, a synonime of the anas bernicla. See ANAS.

CLAMP *in a ship*, denotes a piece of timber applied to a mast or yard, to prevent the wood from bursting; and also a thick plank lying fore and aft under the beams of the first orlop, or second deck, and is the same that the rising timbers are to the deck.

CLAMP is likewise the term for a pile of unburnt bricks built up for burning. These clamps are built much after the same manner as arches are built in kilns, *viz.* with a vacuity betwixt each brick's breadth for the fire to ascend by; but with this difference, that instead of arching, they truss over, or over-span; that is, the end of one brick is laid about half way over the end of another, and so till both sides meet within half a brick's length, and then a binding brick at the top finishes the arch

CLAMP-NAILS, such nails as are used to fasten on clamps in the building or repairing of ships.

CLAMPING, in joinery, is the fitting a piece of board with the grain, to another piece of board cross the grain. Thus the ends of tables are commonly clamped, to prevent their warping.

CLANDESTINA, in botany. See LATHRÆA.

CLANDESTINE, any thing done without the knowledge of the parties concerned, or without the proper solemnities. Thus a marriage is said to be clandestine, when performed without the publication of bans, the consent of parents, *&c.*

CLANGULA, in ornithology. See ANAS.

CLAP, in medicine, the first stage of the venereal disease, more usually called a gonorrhœa. See MEDICINE.

CLARAMONT-POWDER, a kind of earth, called *Terra de Baira*, from the place where it is found: it is famous at Venice, for its efficacy in stopping hæmorrhages of all kinds, and in curing malignant fevers.

Precept of CLARE CONSTAT, in Scots law, the warrant of a superior for entering and infefting the heir of his former vassal, without the interposition of an inquest. See SCOTS LAW, title, *Succession in heritable Rights*.

CLARE, a market-town of Suffolk, thirteen miles south of Bury: E. long. 35′, N. lat. 52° 15′. It gives the title of earl to the duke of Newcastle.

CLARE is also the capital of a county of the same name in the province of Connaught, in Ireland, situated about seventeen miles north-west of Limerick: W. long. 9°, N. lat. 52° 40′.

CLARENCIEUX, the second king at arms, so called from the duke of Clarence, to whom he first belonged; for Lionel third son to Edward III. having by his

wife

wife the honour of Clare, in the county of Thomond, was afterwards declared duke of Clarence; which dukedom afterwards efcheating to Edward IV. he made this earl a king at arms. His office is to marfhal and difpofe of the funerals of all the lower nobility, as baronets, knights, efquires, on the fouth fide of the Trent; whence he is fometimes called Surroy, or South-roy, in contradiftinction to Norroy.

CLARENDON. The conftitutions of Clarendon, are certain ecclefiaftical laws drawn up at Clarendon, near Salifbury. They were fixteen in number, all tending to reftrain the power of the clergy, and readily affented to by all the bifhops and barons, the archbifhop Becket excepted, who oppofed them at firft, but was afterwards prevailed upon to fign them. The pope Alexander III. declared againft and annulled moft of them.

CLARENZA, the capital of a duchy of the fame name in the Morea: it is a fea-port town, fituated on the Mediterranean, twenty-fix miles fouth of Petras: E. long. 21° 40′, N. lat. 37° 40′.

CLARET, a name given by the French to fuch of their red wines as are not of a deep or high colour. See WINE.

CLARICHORD, or MANICHORD, a mufical inftrument in form of a fpinnet.

It has forty-nine or fifty ftops, and feventy ftrings, which bear on five bridges, the firft whereof is the higheft, the reft diminifhing in proportion. Some of the ftrings are in unifon, their number being greater than that of the ftops. There are feveral little mortoifes for paffing the jacks, armed with brafs-hooks, which ftop and raife the chords inftead of the feather ufed in virginals and fpinnets: but what diftinguifhes it moft is, that the chords are covered with pieces of cloth, which render the found fweeter, and deaden it fo, that it cannot be heard at any confiderable diftance: whence it comes to be particularly in ufe among the nuns, who learn to play, and are unwilling to difturb the filence of the dormitory.

CLARIFICATION, in chemiftry, the act of clearing and fining any fluid from all heterogeneous matter or feculencies. See CHEMISTRY.

CLARION, a kind of trumpet, whofe tube is narrower, and its tone acuter and fhriller than that of the common trumpet. It is faid that the clarion, now ufed among the Moors and Portuguefe, who borrrowed it from the Moors, ferved anciently for a treble to feveral tumpets, which founded tenor and bafs.

CLARION, in heraldry, a bearing as reprefented in Plate LXV. fig. 5. he bears ruby, three clarions topaz, being the arms of the earl of Bath, by the name of Granville: Guillim is of opinion, that thefe three clarions are a kind of old-fafhioned trumpets; but others fay, that they rather refemble the rudder of a fhip; others, a reft for a lance.

CLARO-OBSCURO, or CLAIR-OBSCURE, in painting, the art of diftributing to advantage the lights and fhadows of a piece, both with regard to the eafing of the eye, and the effect of the whole piece.

CLARO-OBSCURO, or CHIARO-SCURO, is alfo ufed to fignify a defign confifting only of two colours, moft ufually black and white, but fometimes black and yellow; or it is a defign wafhed only with one colour, the fhadows being of a dufky brown colour, and the lights heightened up with white.

The word is alfo applied to two prints of two colours, taken off at twice, whereof there are volumes in the cabinets of the curious in prints.

CLARY, in botany. See SALVIA.

CLARY-WATER, a fpirit drawn from an infufion of the herb clary in fpirit of wine, being a very pleafant and excellent cordial.

CLASMIUM, in natural hiftory, conftitutes a diftinct genus of gypfums by itfelf, being more foft, dull, and opake, than other kinds: it neither gives fire with fteel, nor ferments with aqua fortis; but calcines readily in the fire, and affords a very valuable plafter.

CLASS, an appellation given to the moft general fubdivifions of any thing: thus, animal is fubdivided into the claffes quadrupeds, birds, fifhes, &c. which are again fubdivided into feriefes or orders; and thefe laft into genera. See NATURAL HISTORY, and BOTANY.

CLASS is alfo ufed in fchools, in a fynonymous fenfe with form, for a number of boys all learning the fame thing.

CLASSIC, or CLASSICAL, an epithet chiefly applied to authors read in the claffes at fchools.

This term feems to owe its origin to Tullius Servius, who, in order to make an eftimate of every perfon's eftate, divided the Roman people into fix bands, which he called claffes. The eftate of the firft clafs was not to be under 200 l. and thefe by way of eminence were called *claffici*, claffics: hence authors of the firft rank came to be called claffics, all the reft being faid to be *infra claffem*: thus Ariftotle is a claffic author in philofophy; Aquinus, in fchool-divinity, &c.

CLATHRUS, in botany, a genus of the cryptogamia fungi clafs. This fungus is roundifh, and full of cancelli. The fpecies are four, none of them natives of Britain.

CLATTE, in heraldry, an appellation given to irregular lines, not reducible to thofe commonly ufed. See LINE.

CLAVARIA, in botany, a genus of the cryptogamia fungi clafs. It is fmooth and oblong. The fpecies are eight, feven of which are natives of Britain, *viz.* the piftillaris, or fimple clavaria; the ophiogloffoides, or black clavaria; the digitata, or fingered clavaria; the hypoxylon, or flat clavaria; the coralloides, or yellow clavaria; the faftigiata, or ftinking clavaria; and the mufcoides, or pointed clavaria.

CLAVES INSULÆ, a term ufed in the ifle of Man; where all weighty and ambiguous caufes are referred to a jury of twelve, who are called *claves infulæ*, the keys of the ifland.

CLAVICLES, in anatomy. See Vol. I. p. 175.

CLAVIS properly fignifies a key, and is fometimes ufed in Englifh to denote an explanation of fome obfcure paffages in any book or writing.

CLAUSE, in grammar, denotes a member of a period, or ſentence.

Clause ſignifies alſo an article, or particular ſtipulation in a contract, a charge or condition in a teſtament, *&c.*

CLAUSENBURG, a large city of Tranſilvania, ſituated on the river Samos, about fifty-five miles north-weſt of Hermanſtat: E. long. 20° 50′, N. lat. 47° 10′.

CLAVUS, in antiquity, an ornament upon the robes of the Roman ſenators and knights, which was more or leſs broad, according to the dignity of the perſon: hence the diſtinction of tunica auguſti-clavia and laticlavia.

Clavus, in medicine and ſurgery, is uſed in ſeveral ſignifications: 1. Clavus hyſtericus, is a ſhooting pain in the head, between the pericranium and cranium, which affects ſuch as have the green-ſickneſs. 2. Clavus oculorum, according to Celſus, is a callous tubercle on the white of the eye, taking its denomination from its figure. 3. Clavus imports indurated tubercles of the uterus. 4. Clavus imports a chirurgical inſtrument of gold, mentioned by Amatus Luſitanus, deſigned to be introduced into an exulcerated palate, for the better articulation of the voice. 5. Clavus is a callus or corn on the foot.

CLAW, among zoologiſts, denotes the ſharp-pointed nails with which the feet of certain quadrupeds and birds are furniſhed.

Crab's Claws, in pharmacy, See Crab's claws.

CLAY, in natural hiſtory, a genus of earths, the characters of which are theſe: they are firmly coherent, weighty, and compact; ſtiff, viſcid, and ductile to a great degree, while moiſt; ſmooth to the touch, not eaſily breaking between the fingers, nor readily diffuſible in water, and when mixed not readily ſubſiding from it.

CLAYTONIA, in botany, a genus of the pentandria monogynia claſs. The calix conſiſts of two valves; the corolla has five petals; the ſtigma is trifid; and the capſule has three valves, and contains three ſeeds. The ſpecies are two, none of them natives of Britain.

Cape CLEAR, a promontory in a little iſland on the ſouth-weſt coaſt of Ireland.

CLEAVERS, in botany. See Gallium.

CLEBURY, a market-town of Shropſhire, about 25 miles ſouth-eaſt of Shrewſbury: W. long. 2° 30′, and N. lat. 52° 27′.

CLECHE, in heraldry, a kind of croſs, charged with another croſs of the ſame figure, but of the colour of the field. See Plate LXV. fig. 6.

CLEDGE, among miners, denotes the upper ſtratum of fuller's earth.

CLEF, or Cliff, in muſic, a mark ſet at the beginning of the lines of a ſong, which ſhews the tone or key in which the piece is to begin; or it is a letter marked on any line, which explains the reſt.

CLEIDOMASTOIDEUS, in anatomy. See Vol. I. p. 215.

CLEMA, in antiquity, a twig of the vine, which ſerved as the badge of a centurion's office.

CLEMATIS, in botany, a genus of the polyandria polygynia claſs. It has no calix; the petals are four; and the ſeeds are caudated. There are twelve ſpecies, none of them natives of Britain.

CLEOME, in botany, a genus of plants belonging to the tetradynamia ſiliquoſa claſs. It has three nectariferous glands, one at each ſinus of the calix, excepting the loweſt; the ſiliqua or pod has two valves and one cell. There are fifteen ſpecies, none of them natives of Britain.

CLEPSYDRA, a water-clock, or inſtrument to meaſure time by the fall of a certain quantity of water.

CLERGY, a general name given to the body of eccleſiaſtics of the Chriſtian church, in contradiſtinction to the laity.

The diſtinction of Chriſtians into clergy and laity, was derived from the Jewiſh church, and adopted into the Chriſtian by the apoſtles themſelves: whenever any number of converts were made, as ſoon as they were capable of being formed into a congregation or church, a biſhop or preſbyter, with a deacon, were ordained to miniſter to them. Of the biſhops, prieſts, and deacons, the clergy originally conſiſted; but in the third century, many inferior orders were appointed, as ſubſervient to the office of deacon, ſuch as ſubdeacons, acolythiſts, readers, *&c.*

Benefit of Clergy, is an ancient privilege, whereby one in orders claimed to be delivered to his ordinary, to purge himſelf of felony: this purgation was to be by his own oath, affirming his innocency, and the oath of twelve compurgators, as to their belief of it, before a jury of twelve clerks: if the clerk failed in his purgation, he was deprived of his character, whereby he became a mere layman; or he was to be kept in priſon till a pardon was obtained: but if he purged himſelf, he was ſet at liberty.

CLERK, a word originally uſed to denote a learned man, or man of letters; whence the term became appropriated to church-men, who were from thence called clerks, or clergymen; the nobility and gentry being uſually bred up to the exerciſe of arms, and none left but the eccleſiaſtics to cultivate the ſciences.

Clerk is alſo applied to ſuch as by their courſe of life, exerciſe their pens in any court or office, of which there are various kinds: thus,

Clerk *of the bails*, an officer in the court of king's bench, whoſe buſineſs it is to file all bail-pieces taken in that court, where he always attends.

Clerk *of the check*, an officer belonging the king's court, ſo called, becauſe he has the check and controulment of the yeomen that belong to the king, queen, or prince. He likewiſe, by himſelf or deputy, ſets the watch in the court. There is alſo an officer in the navy of the ſame name, belonging to the king's yards.

Clerk *of the crown*, an officer, in the king's bench, who frames, reads, and records all indictments againſt offenders, there arraigned or indicted of any public crime. He is likewiſe termed clerk of the crown-office, in which capacity he exhibits informations by order of the court, for divers offences.

Clerk *of the crown*, in chancery, an officer whose business it is constantly to attend the lord-chancellor, in person or by deputy, to write and prepare for the great seal special matters of state by commission, both ordinary and extraordinary, *viz.* commissions of lieutenancy, of justices of assize, oyer and terminer, goal-delivery, and of the peace; all general pardons, granted either at the king's coronation, or in parliament: the writs of parliament, with the names of the knights, citizens, and burgesses, are also returned into his office. He also makes out special pardons, and writs of execution on bonds of statute-staple forfeited.

Clerk *of the deliveries*, an officer of the tower, whose function is to take indentures for all stores and ammunition issued from thence.

Clerk *of the errors*, in the court of common pleas, an officer who transcribes and certifies into the king's bench, the tenor of the record of the action on which the writ of error, made out by the cursitor, is brought there to be determined. In the king's bench, the clerk of the errors transcribes and certifies the records of causes, by bill, in that court, into the exchequer. And the business of the clerk of the errors in the exchequer, is to transcribe the records certified thither out of the king's bench, and to prepare them for judgment in the exchequer-chamber.

Clerk *of the essoins*, in the court of common pleas, keeps the essoin-roll, or enters essoins; he also provides parchment, cuts it into rolls, marks the number on them, delivers out all the rolls to every officer, and receives them again when written. See Essoin.

Clerk *of the estreats*, an officer in the exchequer, who every term receives the estreats out of the lord-treasurer's remembrancer's office, and writes them out, to be levied for the crown.

Clerk *of the green cloth*. See Green-cloth.

Clerk *of the hamper*, or *hanaper*, an officer in chancery, whose business is to receive all money due to the king for the seals of charters, letters patent, commissions, and writs; also the fees due to the officers for enrolling and examining them.

Clerk-*comptroller of the king's household*, an officer of the king's court, authorised to allow or disallow the charges of pursuivants, messengers of the green cloth, &c. to inspect and controul all defects of any of the inferior officers; and to sit in the counting-house with the lord-steward and other officers of the household, for regulating such matters.

Clerk *of the king's silver*, an officer of the common pleas, to whom every fine is brought, after it has passed the office of the custos brevium; and who enters the effect of writs of covenant, into a book kept for that purpose, according to which all the fines of that term are recorded in the rolls of the court.

Clerk *of the market*, an officer of the king's house, to whom is given the charge of the king's measures and weights, the standards of those that ought to be used all over England.

Clerk *of the nichils*, or *nihils*, an officer of the exchequer, who makes a roll of all such sums as are nichilled by the sheriffs upon their estreats of green wax, and delivers them in to the remembrancer of the treasury, to have execution done upon them for the king. See Nihil.

Clerk *of the outlawries*, an officer of the common pleas, and deputy to the attorney-general, for making out all writs of capias utlagatum, after outlawry, to which there must be the king's attorney's name.

Clerk *of the paper-office*, an officer belonging to the king's bench, whose business is to make up the paper-books of special pleadings in that court.

Clerk *of the peace*, an officer belonging to the sessions of the peace, whose business is to read indictments, inrol the proceedings, and draw the process: he likewise certifies into the king's bench, transcripts of indictments, outlawries, attainders and convictions had before the justices of peace, within the time limited by statute, under a certain penalty. This office is in the gift of the custos rotulorum, and may be executed by deputy.

Clerk *of the pells*, an officer that belongs to the exchequer, whose business is to enter every teller's bill into a parchment roll called *pellis receptorum*, and to make another roll of payments called *pellis exituum*.

Clerk *of the petty bag*, an officer of the court of chancery, whereof there are three, the master of the rolls being the chief: their business is to record the return of all inquisitions out of every shire, to make out patents of customers, gaugers, comptrollers, &c. liberates upon extents of statutes-staple, *conge d'elires* for bishops, summons of the nobility, clergy, and burgesses to parliament, and commissions directed to knights and others, of every shire, for assessing subsidies and taxes.

Clerk *of the pipe*, an officer of the exchequer, who having the accounts of all debts due to the king delivered out of the remembrancer's office, charges them in a great roll folded up like a pipe. He writes out warrants to sheriffs, to levy the said debts on the goods and chattels of the debtors: and if they have no good, then he draws them down, to the treasurer's remembrancer, to write estreats against their lands.

Clerk *of the pleas*, an officer of the exchequer, in whose office all the officers of the court, having special privilege, ought to sue, or be sued, in any action. In this office also actions at law may be prosecuted by other persons, but the plaintiff ought to be tenant or debtor to the king, or some way accountable to him. The under-clerks are attorneys in all suits.

Clerks *of the privy-seal*, four officers that attend the lord privy-seal, for writing and making out all things that are sent by warrant from the signet to the privy-seal, and to be passed the great-seal; and likewise to make out privy-seals, upon special occasions of his majesty's affairs, as for loan of money, or the like.

Clerk *of the rolls*, an officer of the chancery, whose business is to make searches after, and copies of deeds, officers, &c.

Clerk *of the signet*, an officer continually attending upon his majesty's principal secretary, who has the custody of the privy-signet, as well for sealing the king's

king's private letters, as thofe grants which pafs the king's hand by bill figned. There are four of thefe officers, who have their diet at the fecretary's table.

CLERK, or WRITER, *to the fignet*, in Scots law. See SCOTS LAW, title 3.

Six CLERKS, officers in chancery, next in degree below the twelve mafters, whofe bufinefs is to inrol commiffions, pardons, patents, warrants, *&c.* which pafs the great feal: they were anciently clerici, and forfeited their places if they married. Thefe are alfo attorneys for parties in fuits depending in the court of chancery.

CLERK *of the treafury*, an officer belonging to the court of common pleas, who has the charge of keeping the records of the court, makes out all records of *nifi prius*, and likewife all exemplifications of records being in the treafury. He has the fees due for all fearches; and has under him an under-keeper, who always keeps one key of the treafury door.

CLERK *of the warrants*, an officer of the common pleas, whofe bufinefs is to enter all warrants of attorney for plaintiffs and defendants in fuit; and to inroll deeds of bargain and fale, that are acknowledged in court, or before a judge. His office is likewife to eftreat into the exchequer all iffues, fines, eftreats, and amercements, which grow due to the crown in that court.

CLERMONT, a city and bifhop's fee of France, in the territory of Auvergne, and province of Lyonois, about feventy-five miles weft of Lyons: E. long. 3° 20′ and N. lat. 45° 42′.

CLERODENDRUM, in botany, a genus of the didynamia-angiofpermia clafs. The calix is bell fhaped, and divided into five fegments; the tube of the corolla is filiform; the limbus is divided into five equal parts; the ftamina are very long; and the berry contains but one feed. The fpecies are two, both natives of the Indies.

CLEROMANCY, a fort of divination performed by throwing lots, which were generally black and white beans, little clods of earth, or pebbles; alfo dice, or fuch like things, diftinguifhed by certain characters. They caft the lots into a veffel, and having made fupplication to the gods to direct them, drew them out, and, according to the characters, conjectured what fhould happen to them.

CLETHRA, in botany, a genus of the decandria monogynia clafs. The calix is divided into five fegments; the petals are five; the ftigma is trifid; and the capfule has three cells and three valves. There is but on fpecies, *viz.* the alnifolia, a native of Carolina.

CLEVES, or CLEF, the capital of the dutchy of Cleve, in the circle of Weftphalia, in Germany, fituated near the weftern fhore of the river Rhine: E. long. 5° 36′, and N. lat. 51° 40′. It is fubject to the king of Pruffia.

CLEVELAND, a diftrict in the north-riding of Yorkfhire, from which the noble family of Fitzroy takes the title of duke.

CLIENT, among the Romans, a citizen who put himfelf under the protection of fome great man, who, in refpect of that relation, was called patron.

This patron affifted his client with his protection, intereft, and goods; and the client gave his vote for his patron, when he fought any office for himfelf or his friends. Clients owed refpect to their patrons, as thefe owed them their protection.

The right of patronage was appointed by Romulus, to unite the rich and poor together in fuch a manner, as that one might live without contempt, and the other without envy; but the condition of a client, in courfe of time, became little elfe but a moderate flavery.

CLIENT is now ufed for a party in a lawfuit, who has turned over his caufe into the hands of a counfellor or follicitor.

CLIFFORTIA, in botany, a genus of the diœcia polyandria clafs. The calix of the male confifts of three leaves; it has no corolla; and the ftamina are about thirty. The calix of the female confifts likewife of three leaves; and the corolla is wanting; the ftyli are two; and the capfule is bilocular, and contains one feed. The fpecies are four, all natives of Æthiopia.

CLIMACTERIC, among phyficians, a critical year in a perfon's life, in which he is fuppofed to ftand in great danger of death.

According to fome, every feventh year is a climacteric; but others allow only thofe years produced by multiplying 7 by the odd number 3, 5, 7, and 9, to be climacterical. Thefe years, they fay, bring with them fome remarkable change with refpect to health, life, or fortune; the grand climacteric is the fixty-third year; but fome, making two, add to this the eighty-firft: the other remarkable climacterics are the feventh, twenty-firft, thirty-fifth, forty ninth, and fifty fixth.

CLIMATE, in geography, a fpace upon the furface of the terreftrial globe, contained between two parallels, and fo far diftant from each other, that the longeft day in one differs half an hour from the longeft day in the other parallel. See GEOGRAPHY.

CLIMAX, or GRADATION, in rhetoric, a figure wherein the word or expreffion which ends the firft member of a period begins the fecond, and fo on; fo that every member will make a diftinct fentence, taking its rife from the next foregoing, till the argument and period be beautifully finifhed; as in the following gradation of Dr Tillotfon. "After we have practifed good actions a while, they become eafy; and when they are eafy, we begin to take pleafure in them; and when they pleafe us, we do them frequently; and by frequency of acts, a thing grows into a habit; and confirmed habit is a fecond kind of nature; and fo far as any thing is natural, fo far it is neceffary; and we can hardly do otherwife; nay, we do it many times, when we do not think of it."

CLINCH, in the fea-language, that part of a cable which is bended about the ring of the anchor, and then feized, or made faft.

CLINCHING, in the fea-language, a kind of flight caulking ufed at fea, in a profpect of foul weather, about the pofts: it confifts in driving a little oakum into their feams, to prevent the water's coming in at them.

CLINIC,

CLINIC, a term applied by the ancient church-hiſtorians, to thoſe who received baptiſm on their death-bed.

CLINIC *medicine*, was particularly uſed for the method of viſiting and treating ſick perſons in bed, for the more exact diſcovery of all the ſymptoms of their diſeaſe.

CLINOIDES, in anatomy. See Vol. I. p. 158.

CLINOPODIUM, in botany, a genus of the didynamia gymnoſpermia claſs. The involucrum is hoary. The ſpecies are three, only one of which is a native of Britain, *viz.* the vulgare, or great wild baſil.

CLIO, in zoology, a genus of inſects belonging to the order of vermes molluſca; the body is oblong, and fitted for ſwimming; and it has two membranaceous wings placed oppoſite to each other. The ſpecies are three, principally diſtinguiſhed by the ſhape of their vagina, and are all natives of the ocean.

CLIPEUS, in natural hiſtory, a name given to the flat depreſſed centroniæ, from their reſembling a ſhield. See CENTRONIA.

CLITORIA, in botany, a genus of the diadelphia decandria claſs. The vexillum is large, open, plaited, and covers the alæ. The ſpecies are five, all natives of the Indies.

CLITORIS, in anatomy. See Vol. I. p. 276.

CLOACA, in Roman antiquity, the common ſewer, by which the filth of the city of Rome was carried away.

CLOCK, a kind of movement, or machine, ſerving to meaſure time.

The invention of clocks is attributed to Pacificus, archdeacon of Verona, who lived in the time of Lotharius: others aſcribe it to Boetius, about the year 510: be that as it will, it is certain, that the art of making clocks, ſuch as are now in uſe, was either firſt invented, or at leaſt retrieved in Germany, about 230 years ago; and the invention of pendulum clocks, ſo late as the laſt age, is diſputed between Huygens and Galileo. For the principles of *Clock* and *Watch Work*, ſee WATCH.

CLOGHER, a city and biſhop's ſee of Ireland, in the county of Tyrone, and province of Ulſter, ſituated twelve miles weſt of Armagh: W. long. 7° 30′, and N. lat. 54° 16′.

CLOISTER, an habitation ſurrounded with walls, and inhabited by religious.

In a more general ſenſe, it is uſed for a monaſtery of religious of either ſex. In the firſt ſenſe, it is the principal part of a regular monaſtery, being a ſquare ſurrounded with walls or buildings. It is commonly placed between the church, the chapter-houſe, and refectory, underneath the dormitory.

CLOSE, in heraldry. When any bird is drawn in a coat of arms with its wings cloſe down about it, (*i. e.* not diſplayed), and in a ſtanding poſture, they blazon it by this word *cloſe*; but if it be flying, they call it *volant*. See VOLANT.

CLOT-*bird*. See FRINGILLA.

CLOTH, in commerce, a manufacture made of wool, wove in the loom.

Cloths are of divers qualities, fine or courſe. The goodneſs of cloth, according to ſome, conſiſts in the following particulars. 1. That the wool be of a good quality, and well dreſſed. 2. It muſt be equally ſpun, carefully obſerving that the thread of the warp be finer and better twiſted than that of the woof. 3. The cloth muſt be well wrought, and beaten on the loom, ſo as to be every where equally compact. 4. The wool muſt not be finer at one end of the piece than in the reſt. 5. The liſts muſt be ſufficiently ſtrong, of the ſame length with the ſtuff, and muſt conſiſt of good wool, hair, or oſtrich-feathers; or, what is ſtill better, of Daniſh dog's hair. 6. The cloth muſt be free from knots, and other imperfections. 7. It muſt be well ſcoured with fuller's earth, well fulled with the beſt white ſoap, and afterwards waſhed in clear water. 8. The hair or nap muſt be well drawn out with the teazel, without being too much opened. 9. It muſt be ſhorn cloſe without making it thread-bare. 10. It muſt be well dried. 11. It muſt not be tenter-ſtretched, to force it to its juſt dimenſions. 12. It muſt be preſſed cold, not hot preſſed, the latter being very injurious to woolen cloth.

Manufacturing of white cloths which are intended for dying.

The beſt wool for the manufacturing of cloths are thoſe England and Spain, eſpecially thoſe of Lincolnſhire and Segovia. To uſe thoſe wools to the beſt advantage, they muſt be ſcoured, by putting them into a liquor ſomewhat more than lukewarm, compoſed of three parts fair water, and one of urine. After the wool has continued long enough in the liquor to ſoak, and diſſolve the greaſe, it is drained and well waſhed in running water. When it feels dry, and has no ſmell but the natural one of the ſheep, it is ſaid to be duly ſcoured.

After this it is hung to dry in the ſhade, the heat of the ſun making it harſh and inflexible: when dry, it is beat with rods upon hurdles of wood, or on cords, to cleanſe it from duſt, and the groſſer filth; the more it is thus beat and cleanſed, the ſofter it becomes, and the better for ſpinning. After beating, it muſt be well picked, to free it from the reſt of the filth that had eſcaped the rods.

It is now in a proper condition to be oiled, and carded on large iron cards, placed ſlopewiſe. Olive oil is eſteemed the beſt for this purpoſe: one fifth of which ſhould be uſed for the wool intended for the woof, and a ninth for that deſigned for the warp. After the wool has been well oiled, it is given to the ſpinners, who firſt card it on the knee with ſmall fine cards, and then ſpin it on the wheel, obſerving to make the thread of the warp ſmaller by one third than that of the woof, and much compacter twiſted.

The thread thus ſpun, reeled, and made into ſkeins, that deſigned for the woof is wound on little tubes, pieces of paper, or ruſhes, ſo diſpoſed, as that they may be eaſily put in the eye of the ſhuttle. That for the warp is wound on a kind of large wooden bobbins, to diſpoſe it for warping. When warped, it is ſtiffened with ſize, the beſt of which is that made of ſhreds of

of parchment, and when dry, is given to the weavers, who mount it on the loom.

The warp thus mounted, the weavers, who are two to each loom, one on each ſide, tread alternately on the treddle, firſt on the right ſtep, and then on the left, which raiſes and lowers the threads of the warp equally; between which they throw tranſverſely the ſhuttle from the one to the other: and every time that the ſhuttle is thus thrown, and a thread of the woof inſerted within the warp, they ſtrike it conjunctly with the ſame frame, wherein is faſtened the comb or reed, between whoſe teeth the threads of the warp are paſſed, repeating the ſtroke as often as is neceſſary.

The weavers having continued their work till the whole warp is filled with the woof, the cloth is finiſhed; it is then taken off the loom by unrolling it from the beam whereon it had been rolled in proportion as it was wove; and now given to be cleanſed of the knots, ends of threads, ſtraws, and other filth, which is done with iron nippers.

In this condition it is carried to the fullery, to be ſcoured with urine, or a kind of potter's clay, well ſteeped in water, put along with the cloth in the trough wherein it is fulled. The cloth being again cleared from the earth or urine, is returned to the former hands to have the leſſer filth, ſmall ſtraws, *&c.* taken off as before: then it is returned to the fuller to be beat and fulled with hot water, wherein a ſuitable quantity of ſoap has been diſſolved; after fulling, it is taken out to be ſmoothed, or pulled by the liſts lengthwiſe, to take out the wrinkles, crevices, *&c.*

The ſmoothing is repeated every two hours, till the fulling be finiſhed, and the cloth brought to its proper breadth: after which it is waſhed in clear water, to purge it of the ſoap, and given wet to the carders to raiſe the hair or nap on the right ſide with the thiſtle or weed. After this preparation the clothworker takes the cloth, and gives it its firſt cut or ſhearing: then the carders reſume it, and after wetting, give it as many more courſes with the teazle, as the quality of the ſtuff requires, always obſerving to begin againſt the grain of the hair, and to end with it; as alſo to begin with a ſmoother thiſtle, proceeding ſtill with one ſharper and ſharper, as far as the ſixth degree.

After theſe operations, the cloth being dried, is returned to the cloth worker, who ſheers it a ſecond time, and returns it to the carders, who repeat their operation as before, till the nap be well ranged on the ſurface of the cloth, from one end of the piece to the other.

The cloth thus wove, ſcoured, napped, and ſhorn, is ſent to the dyer; when dyed, it is waſhed in fair water, and the worker takes it again wet as it is, lays the nap with a bruſh on the table, and hangs it on the tenters, where it is ſtretched both in length and breadth ſufficiently to ſmooth it, ſet it ſquare, and bring it to its proper dimenſions, without ſtraining it too much; obſerving to bruſh it afreſh, the way of the nap, while a little moiſt, on the tenters.

When quite dry, the cloth is taken off the tenters, and bruſhed again on the table, to finiſh the laying of the nap; after which it is folded, and laid cold under a preſs, to make it perfectly ſmooth and even, and give it a gloſs.

Laſtly, the cloth being taken out of the preſs, and the papers, *&c.* for gloſſing it removed, it is in a condition for ſale or uſe. With regard to the manufacture of mixt cloths, or thoſe wherein the wools are firſt dyed, and then mixt, ſpun and wove of the colours intended, the proceſs, except what relates to the colour, is moſtly the ſame with that juſt repreſented.

CLOUD, a collection of vapours ſuſpended in the atmoſphere. See PNEUMATICS.

CLOVE-TREE, in botany. See CARYOPHYLLUS.

CLOVE, a term uſed in weights of wool. Seven pounds make a clove.

In Eſſex, eight pounds of cheeſe and butter go to the clove.

CLOVE-JULY-FLOWER. See CARYOPHYLLUS.

CLOVER-GRASS, in botany. See TRIFOLIUM.

CLOYNE, a city and biſhop's ſee of Ireland, in the county of Cork, and province of Munſter, about fifteen miles eaſt of Cork: W. long. 8°, and N. lat. 51° 40′.

CLUPEA, or herring, in ichthyology, a genus belonging to the order of abdominales. The upper jaw is furniſhed with a ſerrated myſtache; the branchioſtege membrane has eight rays; a ſcaly ſerrated line runs along the belly from the head to the tail; and the belly-fins have frequently nine rays. There are 11 ſpecies, *viz.*

1. The harengus, or common herring, has no ſpots, and the under jaw is longer than the upper one. A herring dies immediately after it is taken out of the water, whence the proverb ariſes, *As dead as a herring*. The fleſh is every where in great eſteem, being fat, ſoft, and delicate, eſpecially if it is dreſt as ſoon as caught; for then it is incomparably better than on the next day. There are vaſt quantities of theſe fiſh taken, ſalted, ſmoak-dried, and conſumed all over Europe. They make a progreſs every year from the ſeas near the north of Scotland, into the Britiſh channel, coming in purſuit of worms and ſmall fiſh, which at that time abound there. There is alſo plenty near Norway and Denmark, from whence they proceed annually as far as the coaſt of Normandy.

The herring-fiſhery is begun both by the Engliſh and Dutch towards the latter end of June; and the Dutch alone employ no leſs than one thouſand ſhips therein, called buſſes, from forty-five to ſixty ton each. The beſt time for catching herrings is from the latter end of September, to the latter end of October; and the nets they make uſe of, are about twenty five yards long, and five deep. They ſometimes faſten ſo many of theſe nets together, as will take in a mile in compaſs. They judge where the herrings lie by the hovering and motion of the ſea-birds, which continually purſue them, in expectation of prey. The fiſhermen row very gently along, letting the nets fall into the ſea,

ſea, and taking their courſes as near as they can againſt the tide; that ſo, when they draw their nets, they may have the aſſiſtance of the tide. As ſoon as any boat has got its load, it makes to the ſhore, and delivers its load to thoſe that waſh and gut them.

Herrings are put into a tub with ſalt or brine, where they lie for twenty-four hours, and are then taken out and put into wicker baſkets and waſhed. After this, they are ſpitted on ſharp wooden ſpits, and hung up in a chimney, built for that purpoſe, at ſuch diſtances, that the ſmoke may have free acceſs to them all. Theſe places will hold ten or twelve thouſand at a time; and they kindle billets on the floor in order to dry them. This done, they ſhut the doors, having before ſtopped up all the air-holes. This they repeat every quarter of an hour, inſomuch that a ſingle laſt of herrings requires five hundred billets to dry them. A laſt is ten barrels, and each barrel contains about one thouſand herrings. When they are ſmoke-dried in this manner, they are called red herrings. Salt herrings, and pickled herrings, are cured after a different manner; the laſt of which were formerly beſt done by the Dutch; but now the Scotch and Engliſh are become their rivals in that trade. Herrings always ſwim in ſhoals, delighting to be near the ſhore. They ſpawn but once a year, that is about the beginning of November; a little before which, like moſt other fiſh, they are in higheſt ſeaſon.

There are likewiſe herrings on the coaſt of North America, but they are not ſo plenty as in Europe; and they never go farther ſouth than the rivers of Carolina. There are none near Spain, Portugal, in the Mediterranean, nor on the coaſt of Africa.

2. The ſprattus has 13 rays in the back-fin. It is a native of the European ſeas, and has a great reſemblance to the herring, only it is of a leſs ſize.

3. The aloſa, has a forked ſnout, and black ſpots on the ſides. It is found in the European ſeas.

4. The encraſicolus, or anchovy, has its upper jaw longer than the under one, and is found in the European ſeas. It is about three inches long, and is frequently uſed as a pickle.

5. The atherinoides has a ſhining line on each ſide, and ſmall belly-fins. It is a native of Surinam.

6. The thriſſa has 28 rays in the fin at the anus. It is found in the Indian ocean.

7. The ſima has yellow fins, thoſe of the belly being very ſmall. The mouth is flat; the upper jaw is very ſhort; the body is of a ſhining ſilver colour; and the fins are yellow. It is a native of Aſia.

8. The ſternicla has no belly-fins, and the body is broad. It is a native of Surinam.

9. The myſtus is ſhaped like a ſword, and the fins at the anus are united. It is found in the Indian ocean.

10. The tropica has a wedge-like tail, and a white, broad, compreſſed body; and the tail is wedge-ſhaped. It is found at Aſcenſion iſland.

11. The ſinenſis is very like the common herring, but broader. It has no teeth, and is a native of China.

CLUSIA, in botany, a genus of the polygamia monœcia claſs. The calix of the male conſiſts of ſix leaves; the corolla has five petals; and the ſtamina are numerous. The calix and corolla of the female are the ſame as thoſe of the male; the nectarium includes the germen and united antheræ; and the capſule has five cells, five valves, and a ſtuffed pulp. The ſpecies are four, all natives of America.

CLUTIA, in botany, a genus of the diœcia gynandria claſs. The calix and corolla, both of the male and female, conſiſt of five leaves; the ſtyli are three; and the capſule has three cells and one ſeed.

CLYDE, a river in Scotland, which, ariſing in Annandale, runs north-weſt by Lanerk, Hamilton, and Glaſgow, and falls into the Frith of Clyde, over-againſt the iſle of Bute.

CLYMENUM, in botany. See LATHYRUS.

CLYPEOLA, in botany, a genus of the tetradynamia ſiliculoſa claſs. The pod is emarginated, roundiſh, entire, compreſſed, and deciduous. The ſpecies are two, none of them natives of Britain.

CLYPEUS, or CLYPEUM, a ſhield or buckler. See SHIELD.

CLYSSUS, an extract prepared, not from one, but ſeveral bodies mixt together: and, among the moderns, the term is applied to ſeveral extracts procured from the ſame body, and then mixed together. Thus, if from wormwood we draw the water, ſpirit, oil, ſalt, and tincture, and according to the rules of art re-unite theſe into a maſs compounded of them all, and containing the joint virtues of all, we have a clyſſus of wormwood.

CLYSTER, is a liquid remedy, to be injected chiefly at the anus into the larger inteſtines. It is uſually adminiſtered by the bladder of a hog, ſheep, or ox, perforated at each end, and having at one of the apertures an ivory pipe faſtened with pack-thread. But the French, and ſometimes the Dutch, uſe a pewter ſyringe, by which the liquor may be drawn in with more eaſe and expedition than in the bladder, and likewiſe more forcibly expelled into the large inteſtines. This remedy ſhould never be adminiſtered either too hot or too cold, but tepid; for either of the former will be injurious to the bowels.

Clyſters are prepared of different ingredients, according to the different intentions propoſed.

Clyſters are ſometimes uſed to nouriſh and ſupport a patient who can ſwallow little or no aliment, by reaſon of ſome impediment in the organs of deglutition. In which caſe they may be made of broth, milk, ale, and decoctions of barley and oats with wine. The Engliſh introduced a new kind of clyſter, made of the ſmoke of tobacco, which has been uſed by ſeveral other nations, and appears to be of conſiderable efficacy when other clyſters prove ineffectual, and particularly in the iliac paſſion, in the *hernia incarcerata*, and for the recovery of drowned perſons.

CNEORUM, in botany, a genus of the triandria monogynia claſs. The calix has three teeth; and the corolla has three equal petals. There is but one ſpecies, *viz.* the tricoccum, a native of Spain.

CNICUS,

CNICUS, or Saffron flower, in botany, a genus of the syngenesia polygamia æqualis class. The calix is ovated, and imbricated with spinous branches; and the corollæ are equal. The species are seven, none of them natives of Britain.

COA, in botany. See Hippocratea.

COACH, a commodious vehicle for travelling, so well known as to need no description. Their invention was owing to the French about the reign of Francis I.

COAGULATION, in a general sense, imports a certain change in the state of any liquor, by means of which, instead of retaining its fluidity, it becomes more or less consistent, according to the degree of coagulation.

COAGULUM, is the same with what in English we call runnet, or rather the curd formed thereby.

COAL, or Pit-coal, in natural history. See Lithanthrax.

Cannel-Coal, in natural history. See Ampelites.

Small-Coal, a sort of charcoal prepared from the spray and brush-wood stripped off from the branches of coppice-wood, sometimes bound in bavins for that purpose, and sometimes charred without binding, and then it is called coming it together.

COALITION, the re-union of the parts of a body before separated.

COAT, or Coat of Arms, in heraldry, a habit worn by the ancient knights over their arms both in war and tournaments, and still borne by heralds at arms. It was a kind of fur-coat, reaching as low as the navel, open at the sides with short sleeves, sometimes furred with ermine and hair, upon which were applied the armories of the knights embroidered in gold and silver, and enamelled with beaten tin-coloured black, green, red, and blue; whence the rule never to apply colour on colour, nor metal on metal. The coats of arms were frequently open, and diversified with bands and fillets of several colours, alternately placed, as we still see cloths scarleted, watered, &c. Hence they were called devises, as being divided and composed of several pieces sewed together; whence the words *fasse*, *pale*, *chevron*, *bend*, *cross*, *saltier*, *lozenge*, &c. which have since become honourable pieces, or ordinaries of the shield. See Cross, Bend, Chevron, &c.

Coats of arms and banners were never allowed to be worn by any but knights and ancient nobles.

Coat, in anatomy. See Part VI.

Coat *of* Mail. See Mail.

COATI, in zoology, a synonime of a species of viverra and ursus. See Viverra and Ursus.

COBALT, in chemistry, a genus of fossils, of the order of the asphurelata: it is a dense, compact, and ponderous mineral, very bright and shining, and much resembling some of the antimonial ores. See Antimony, and Chemistry, p. 139, 140, 141.

It is sometimes found of a deep blueish-black, very heavy and hard, and of a granulated structure, looking like a piece of pure iron where fresh broken: at other times it is found more compact, not granulated, but resembling a mass of melted lead on the surface. These are the more ordinary appearances of cobalt, besides which there are other accidental varieties of it, being sometimes found of a florid red, or a red debased by mixtures of grey, black, or yellow; and in this state, it either forms an uniform mass, or a beautifully striated and ridged one.

From this mineral are produced the several kinds of arsenic, zaffre, and smalt. See Chemistry, p. 145.

COBELLA, in zoology, the trivial name of a species of coluber. See Coluber.

COBITIS, the loache, in ichthyology, a genus of fishes belonging to the order of abdominales. The eyes are in the upper part of the head. The branchiostege membrane has from four to five rays; and the body is nearly of an equal thickness throughout. The species are five, *viz.* the anablops, with two cirri, a depressed head, and prominent eyes. It is found on the coasts of Surinam. 2. The barbatula, with six cirri, and a compressed smooth head. 3. The tænia, with six cirri, and a prickle below the eye. The above two are found in the fresh-waters of Europe. 4. The fossilis, with eight cirri, and a prickle above the eye. It is a native of Europe. 5. The heteroclita, has no cirri; and the back-fin and that at the anus are full of white spots. It is a native Carolina.

COBLENTZ, a large city of Germany, in the archbishopric of Triers, and circle of the Lower Rhine, situated at the confluence of the Rhine and Moselle, fifty two miles north-east of Triers, and thirty-six south of Cologne: E. long. 7° 15′, N. lat. 50° 30′.

COBLON, a port-town of the hither India, situated on Coromandel-coast, twelve miles south of Fort St George: E. long. 80°, N. lat. 12. 50′.

COBWEB, in physiology, the fine net-work which spiders spin out of their own bowels, in order to catch their prey. See Aranea.

COCCEIRA in botany. See Theobroma.

COCCIFEROUS plants, the same with bacciferous. See Bacciferous.

COCCINELLA, in zoology, a genus of insects, of the coleoptera order. The antennæ are fulclavated, and truncated; the polypi are shaped like a hart; the body is of a hemispherical figure; the breast and elytra are marginated; and the belly is plain. The species are forty-nine, mostly distinguishable by the number and colour of the spots on their wings, and the plants upon which they live.—The coccinella cacti, a native of the warmer parts of America, is the famous cochineal animal, so highly valued in every part of the world for the incomparable beauty of its red colour, which it equally communicates to wool, silk, linen, and cotton. It is bred on a plant known in Oaxaca in New Spain, and all those parts where it abounds, by the name of nopal, or nopalleca, the Indian fig-tree, which, except in the difference of the foliage, resembles the tunos, so common in the kingdom of Andalusia; the leaf of the tuna being broad, flat and prickly, and that of the nopal, oblong, with several eminences;

eminences; and inſtead of ſpines has a fine ſmooth membrane, of a permanent and lively green.

The method of planting the nopal is by making rows of holes about half a yard deep, and about two yards diſtant from one another. In each of theſe holes is placed one or two leaves of the nopal, in a flat poſition, and then covered with earth. This leaf ſoon after ſhoots up into a ſingle ſtem, which during its growth divides into ſeveral branches, and theſe ſucceſſively produce freſh leaves, the largeſt being neareſt to the ſtem, which is full of knots, as are alſo the branches, and from theſe the leaves have their origin. The uſual height of this plant is about three yards, which it ſeldom exceeds. The ſeaſon when the nopal diſplays all its beauty and vigour, is like that of other plants, from the ſpring to the autumn, which at Oaxaca and other parts of North America is at the ſame time as in Spain. Its bloſſom is ſmall, of a bright red, and in the ſhape of a bud; from the centre of which proceeds the tuna, a name given to its fruit; and as this increaſes the bloſſom fades, till at length it falls. When the tuna, or fig, is ripe, the outward ſkin becomes white; but the pulp is ſo fully impregnated with a deep red, that it tinges the urine of thoſe who eat it of a blood colour, a circumſtance attended with no ſmall uneaſineſs to thoſe who are unacquainted with this particular. Few fruits, however, are either more wholeſome or pleaſant.

The ground where the nopal is intended to be planted, muſt be carefully cleanſed from all kinds of weeds, as they drain the ſoil of thoſe juices which the nopal requires. Alſo after the cochineal is taken from the plant, which is never done till the inſects are arrived at perfection, all the ſuperfluous leaves are plucked off, that they may be ſucceeded by others the following year. For it muſt be obſerved, that the cochineal which are bred on young plants thrive much better, and are of a finer quality, than thoſe produced on ſuch as have ſtood ſome years.

The cochineal was formerly imagined to be a fruit or ſeed of ſome particular plant; an error which probably aroſe from an ignorance of the manner in which it is propagated; but at preſent every one is convinced of its being an inſect, agreeably to its name, ſignifying a woodlouſe, which generally breeds in damp places, eſpecially in gardens. Theſe inſects, by rolling themſelves up, form a little ball ſomething leſs than a pea, and in ſome places are known by the name of Baquilas de San Anton, *i. e.* St Anthony's little cows: and ſuch is the figure of the cochineal, except that it has not the faculty of rolling itſelf up; and its magnitude, when at its full growth, does not exceed that of a tick, common in dogs and other animals.

Theſe inſects breed and are nouriſhed on the nopals, where their eggs are placed among the leaves; the juice of the plant, which is their ſole nouriſhment, becomes converted into their ſubſtance; when, inſtead of being thin and wateriſh, and, to all outward appearance, of little or no uſe, is rendered a moſt beautiful crimſon colour. The plant is in May or June in its moſt vigorous ſtate, and at this moſt favourable ſeaſon the eggs are depoſited: and in the ſhort ſpace of two months, from an animalcule, the inſect grows up to the ſize abovementioned; but its infant ſtate is expoſed to a variety of dangers; the violent blaſts of the north wind ſweep away the eggs from the foliage of the plant; and, what is equally fatal to their tender conſtitutions, ſhowers, fogs, and froſts, often attack them, and deſtroy the leaves, leaving the careful cultivator this only reſource, namely, that of making fires at certain diſtances, and filling the air with ſmoke, which frequently preſerves them from the fatal effects of the inclemency of the weather.

The breeding of cochineal is alſo greatly obſtructed by birds of differed kinds, which are very fond of theſe inſects; and the ſame danger is to be apprehended from the worms, *&c.* which are found among the plantations of nopals: ſo that unleſs conſtant care be taken to fright the birds away from the plantation, and to clear the ground of thoſe various kinds of vermin, which multiply ſo faſt in it, the owner will be greatly diſappointed in his expectations.

When the inſects are at their full growth, they are gathered and put into pots of earthen ware; but great attention is requiſite to prevent tnem from getting out, as, in that caſe, great numbers of them would be loſt; though there is no danger of it, where they are at liberty on the nopal leaves, thoſe being their natural habitation; and where they enjoy a plenty of delicious food; for, though they often remove from one leaf to another, they never quit the plant; nor is it uncommon to ſee the leaves entirely covered with them, eſpecially when they are arrived at maturity. When they have been confined ſome time in theſe pots, they are killed and put in bags. The Indians have three different methods of killing theſe inſects, one by hot water, another by fire, and a third by the rays of the ſun: and to theſe are owing the ſeveral gradations of the colour, which in ſome is dark, and in others bright; but all require a certain degree of heat. Thoſe therefore who uſe hot water are very careful to give it the requiſite heat, and that the quantity of water be proportioned to the number of inſects. The method of killing the creatures by fire is to put them on ſhovels into an oven moderately heated for that intention; the fine quality of the cochineal depending on its not being over dried at the time of killing the inſects: and it muſt be owned, that among the ſeveral ways made uſe of to deſtroy this valuable creature, that of the rays of the ſun ſeems to bid faireſt for performing it in the moſt perfect manner.

Beſides the precaution requiſite in killing the cochineal, in order to preſerve its quality, it is equally neceſſary to know when it is in a proper ſtate for being removed from the leaves of the nopal; but as experience only can teach the cultivator this neceſſary criterion, no fixed rule can be laid down. Accordinly in thoſe provinces where the cultivation of theſe inſects is chiefly carried on, thoſe gathered by Indians of one village differ from thoſe gathered in another; and even thoſe gathered by one perſon in the ſame village, are often different from thoſe gathered by another; every individual adhering to his own method.

The cochineal infect may, in fome circumftances, be compared to the filk worm, particularly in the manner of depofiting its eggs. The infects deftined for this particular are taken at a proper time of their growth, and put into a box well clofed, and lined with a coarfe cloth that none of them be loft: and in this confinement they lay their eggs and die. The box is kept clofe fhut till the time of placing the eggs on the nopal, when, if any motion is perceived, it is a fufficient indication that the animalcule has life, tho' the egg is fo minute as hardly to be perceived; and this is the feed placed on the foliage of the nopal, and the quantity contained in the fhell of a hen's egg is fufficient for covering a whole plant. It is remarkable that this infect does not, or at leaft in any vifible manner, injure the plant, but extracts its nourifhment from the moft fucculent juice, which it fucks by means of its probofcis through the fine teguments of the leaves.

The principal countries where the cochineal infects are bred, are Oaxaca, Flafcala, Chulula, Nueva Gallicia, and Chiapa, in the kingdom of New Spain; and Hambato, Loja, and Tucuman in Peru: but it is only in Oaxaca, that they are gathered in large quantities, and form a branch of commerce, the cultivation of thefe little creatures being there the chief employment of the Indians.

COCCOTHRAUSTES, in ornithology, the trivial name of a fpecies of loxia. See Loxia.

COCCULUS INDICUS, the name of a poifonous berry, too frequently ufed by brewers in order to render their malt liquors intoxicating. It is the fruit of the menifpermum cocculus. See Menispermum.

COCCUS, in zoology, a genus belonging to the order of hemiptera. The roftrum proceeds from the breaft; the belly is briftly behind; the wings of the male are erect; and the female has no wings. The fpecies are twenty-two, denominated principally from the plants they frequent.

COCCYGÆUS musculus, in anatomy. See Vol. I. p. 220.

COCCYX, or Coccygis os, in anatomy. See Vol. I. p. 171.

COCHIN, a port-town of India, on the Malabar-coaft, about on hundred miles fouth of Calicut: W. long. 75°, and N. lat. 9° 30′. Here the Dutch have a factory, and a very ftrong fort.

Cochn china, a kingdom of India, fituated between 104° and 109° E. long. and between 10° and 17° N. lat. being bounded by the kingdom of Tonquin on the north, by the Indian ocean on the eaft and fouth, and by the kingdom of Cambodia on the weft: it is upwards of four hundred miles long, and one hundred and fifty broad, producing chiefly filk and rice.

COCHINEAL. See coccinella.

COCHLEA, the snail-shell, in zoology. See Limax.

Cochlea, in anatomy. See Vol. I. p. 297.

COCHLEARIA, scurvy-grass, in botany, a genus of the tetradynamia filiculofa clafs. The pod is emarginated, turgid, and fcabrous; and the valves are obtufe and gibbous. The fpecies are eight, fix of which are natives of Britain, *viz.* the officinalis, or common fcurvy-grafs, the leaves of which are famous for curing the fcurvy; the groenlandica, or Groenland fcurvy-grafs; the anglica, or common fea fcuryy grafs; the danica, or Danifh fcurvy-grafs; the coronopus, or fwine-creffes; and the armoracia, or horfe-radifh.

COCHLITES, in natural hiftory, an appellation given to the petrified fhells of the cochleæ, or fnails.

COCK, in zoology, the Englifh name of the males of gallinaceous birds, but more efpecially ufed for the common dunghill-cock. See Phasianus.

Cock's-comb, in botany. See Phinanthus.

Cock-pit, a fort of theatre upon which game-cocks fight.

Cock-pit, in a man of war, a place on the lower floor, or deck, abaft the main-capftain, lying between the platform and the fteward's room, where are partitions for the purfer, furgeon, and his mates.

Cock-swain, or Coxon, an officer on board a man of war, who has the care of the barge and all things belonging to it, and muft be alfo ready with his crew to man the boat on all occafions: he fits at the ftern of the boat, and fteers.

COCKERMOUTH, a borough-town of Cumberland, fituated on the river Derwent, near the Irifh fea, about twenty-five miles fouth-weft of Carlifle: W. lon. 3° 10′, and N. lat. 54° 35′. It fends two members to parliament.

COCKET is a feal belonging to the king's cuftom-houfe, or rather a fcroll of parchment fealed and delivered by the officers of the cuftoms to merchants, as a warrant that their merchandifes are cuftomed.

It is alfo ufed for the office where goods tranfported were firft entered, and paid their cuftom, and had a cocket or certificate of difcharge.

COCOA, or Cacao, in botany. See Theobroma.

COCOI, in ornithology. See Arctea.

COCONATO, a town of Italy in the province of Piedmont, about twenty miles eaft of Turin; it is faid to be the birth-place of the famous Columbus, who difcovered America: E. long. 8°, and N. lat. 44° 50′.

COCTION, a general term for all alterations made in bodies by the application of fire or heat.

COD, in ichthyology. See Gadus.

Cod is alfo a term ufed, in fome parts of the kingdom, for a pod. See Pod.

Cod-cape, in geography, a promontory on the coaft of New England, near the entrance of Bofton harbour: W. long. 69° 50′, and N. lat. 42°.

CODDY-MODDY, the Englifh name of a fpecies of larus. See Larus.

CODE, a collection of the laws and conftitutions of the Roman emperors, made by order of Juftinian. See Law.

CODEX, in antiquity, denotes a book or tablet, on which the ancients wrote. It was of the bark of a tree, of ivory, of parchment, or of paper.

CODIA, among botanifts, fignifies the head of any plant, but more particularly a poppy-head, whence its fyrup is called diacodium.

CODICIL,

CODICIL is a writing by way of supplement to a will, when any thing is omitted which the testator would have added, or wants to be explained, altered, or recalled.

CODLIN, an apple useful in the kitchen, being proper for baking.

CODLING, an appellation given to the cod fish, when young. See GADUS.

COECUM, in anatomy. See Vol. I. p. 260.

COEFFICIENTS, in algebra. See Vol. I. p. 80.

COELESTIAL, in general, denotes any thing belonging to the heavens: thus we say, cœlestial observations, the cœlestial globe, *&c.*

COELIAC *artery*, in anatomy. See Vol. I. p. 232.

COELIAC *passion*, in medicine, a kind of flux, or diarrhœa, wherein the aliments, either wholly changed, or only in part, pass off by stool. See MEDICINE.

COELIAC *vein*, in anatomy. See Vol. I. p. 245.

COELOMA, among physicians, a hollow ulcer seated in the cornea tunica of the eye.

COENOBITE, in church-history, a sort of monks in the primitive Christian church. They were so called from living in common; in which they differed from the anachorites, who retired from society.

COENOBITE, in a modern sense, is a religious who lives in a convent or community, under certain rules.

COEUR, in heraldry, a short line of partition in pale, in the centre of the escutcheon, which extends but a little way, much short of the top and bottom, being met by other lines, which form an irregular partition of the escutcheon. See Plate LXV. fig. 7.

COEVORDEN, a town of the province of Overyssel, strongly fortified by the famous Coehorn, on account of its situation, it being the key to the provinces of Groningen and Friezland.

COFFEA, the COFFEE-TREE, in botany, a genus of the pentandria monogynia class. The corolla is hypocrateriform; the stamina are above the tube; the berry is below the flower, and contains two seeds, which are arillated. The species are two, *viz.* the arabica, a native of Arabia and Æthiopia; and the occidentalis, a native of America. The berries of both species have much the same qualities. This fruit is used rather as food than as a medicine. The medical effects expected from it are, to assist digestion, promote the natural secretions, and to prevent or remove a disposition to sleep.

Coffee pays on importation 1 l. 13 s. $6\frac{15}{100}$ d. the hundred weight; the drawback on exportation is 1 l. 10 s. $2\frac{25}{100}$ d. Upon payment of the above duty, the coffee is to be put into warehouses; and upon delivery from thence, if to be consumed in Great Britain, is to pay for every hundred weight 8 l. 8 s. if of the British plantations in America, and 11 l. 4 s. if it comes from any other place.

COFFERER *of the king's household*, a principal officer in the court, next under the comptroller, who, in the counting-house, and elsewhere at other times, has a special charge and oversight of other officers of the house, for their good demeanor and charge in their offices, to all which he pays their wages.

COGENDE, a city of Tartary in Asia, situated in 74° E. long. and 41° N. lat. remarkable for its commerce in musk.

COGGLE. See COGS.

COGGSHALL's *sliding rule*. See SLIDING RULE.

COGITATION, a term used by some for the act of thinking.

COGNATE, in Scots law, any male relation through the mother.

COGNATION, in the civil law, a term for that line of consanguinity which is between males and females, both descended from the same father; as agnation is for the line of parentage between males only descended from the same stock.

COGNI, the capital of Caramania, in the lesser Asia, anciently called Iconium, about two hundred and fifty miles south-east of Constantinople: E. long. 33°, and N. lat. 38°.

COGNITIONIS CAUSA, in Scots law: When a creditor charges the heir of his debitor to enter, in order to constitute the debt against him, and the heir renounces the succession, the creditor can obtain no decreet of constitution of that debt against the heir; but only a decreet subjecting the *hereditas jacens*, or the estate which belonged to the debitor, to his diligence: and this is called a decreet *cognitionis causa*. See SCOTS LAW, title, *Comprisings and adjudications*.

COGNIZANCE, in heraldry. See CREST.

COGNIZANCE, or CONNUSANCE, in law, has divers significations: sometimes it is an acknowledgment of a fine, or confession of something done; sometimes the hearing of a matter judicially, as to take cognizance of a cause; and sometimes a particular jurisdiction, as cognizance of pleas is an authority to call a cause or plea out of another court, which no person can do but the king, except he can shew a charter for it. This cognizance is a privilege granted to a city or town, to hold plea of all contracts, *&c.* within the liberty; and if any one is impleaded for such matters in the courts at Westminster, the mayor, *&c.* of such franchise may demand cognizance of the plea, and that it be determined before them.

COGNIZANCE is also used for a badge on a waterman's or serving-man's sleeve, which is commonly the giver's crest, whereby he is decerned to belong to this or that nobleman or gentleman.

COGS, or COGGLES, a kind of flat-bottomed boats used in rivers.

COHABITATION, denotes the state of a man and a woman who live together like husband and wife, without being legally married.

By the common law of Scotland, cohabitation for year and day, or a complete twelvemonth, is deemed equivalent to matrimony.

CO-HEIR, one who succeeds to a share of an inheritance, to be divided among several.

COHESION, in philosophy, that action by which the particles of the same body adhere together, as if they were but one. See MECHANICS.

COHORT, in Roman antiquity, the name of part of the

the Roman legion, comprehending about ſix hundred men. There were ten cohorts in a legion, the firſt of which exceeded all the reſt, both in dignity and number of men. When the army was ranged in order of battle, the firſt cohort took up the right of the firſt line, the reſt followed in their natural order, ſo that the third was in the centre of the firſt line of the legion, and the fifth on the left, the ſecond between the firſt and third, and the fourth between the third and fifth: the five remaining cohorts formed a ſecond line, in their natural order.

COIF, the badge of a ſerjeant at law, who is called ſerjeant of the coif, from the lawn-coif they wear under their caps when they are created ſerjeants.

The uſe of the coif was to cover the clerical tonſure. See Tonsure.

COIL. See Quoil.

COILON in the ancient Grecian theatres, the ſame with the cavea of the Romans. See Cavea.

COILOPHYLLUM, in botany. See Sarracena.

COIMBRA, a large city of Portugal, in the province of Beira, ſituated on the river Mondego, about nineſix miles north of Liſbon: W. long. 9°, and N. lat. 40° 20′.

COIN denotes all manner of the ſeveral ſtamps and ſpecies of money in any nation. See Money.

Coin, in architecture, a kind of dye cut diagonal-wiſe, after the manner of a flight of a ſtair-caſe, ſerving at bottom to ſupport columns in a level, and at top to correct the inclination of an entablature ſupporting a vault.

Coin is alſo uſed for a ſolid angle compoſed of two ſurfaces inclined towards each other, whether that angle be exterior, as the coin of a wall, a tree, *&c.* or interior, as the coin of a chamber or chimney. See Quoin.

COINAGE, or Coining, the art of making money, as performed either by the hammer or mill.

Formerly the fabric of coins was different from what it is at preſent. They cut a large plate of metal into ſeveral little ſquares, the corners of which were cut off with ſheers. After having ſhaped theſe pieces, ſo as to render them perfectly conformable, in point of weight, to the ſtandard piece, they took each piece in hand again, to make it exactly round, by a gentle hammering. This was called a planchet, and was fit for immediate coining. Then engravers prepared, as they ſtill do, a couple of ſteel maſſes in form of dyes, cut and terminated by a flat ſurface, rounded off at the edges. They engraved or ſtamped on it the hollow of a head, a croſs, a ſcutcheon, or any other figure, according to the cuſtom of the times, with a ſhort legend. As one of theſe dyes was to remain dormant, and the other moveable, the former ended in a ſquare priſm, that it might be introduced into the ſquare hole of the block, which, being fixed very faſt, kept the dye as ſteady as any vice could have done. The planchet of metal was horizontally laid upon this inferior maſs, to receive the ſtamp of it on one ſide, and that of the upper dye, wherewith it was covered, on the other. This moveable dye, having its round engraved ſurface reſting upon the planchet, had at its oppoſite extremity a flat ſquare, and larger ſurface, upon which they gave ſeveral heavy blows, with a hammer of an enormous ſize, till the double ſtamp was ſufficiently, in relievo, impreſſed on each ſide of the planchet. This being finiſhed, was immediately ſucceeded by another, and they thus became a ſtandard coin, which had the degree of fineneſs, the weight and mark, determined by the judgment of the inſpectors, to make it good current money. The ſtrong tempering which was and is ſtill given to the two dyes, rendered them capable of bearing thoſe repeated blows Coining has been conſiderably improved and rendered expeditious, by ſeveral ingenious machines, and by a wiſe application of the ſureſt phyſical experiments to the methods of fining, dying, and ſtamping the different metals.

The three fineſt inſtruments the mint-man uſes, are the laminating engine, the machine for making the impreſſions on the edges of coins, and the mill.

After they have taken the laminæ, or plates of metal, out of the mould into which they are caſt, they do not beat them on the anvil, as was formerly done, but they make them paſs and repaſs between the ſeveral rollers of the laminating engine, which being gradually brought cloſer and cloſer to each other, preſently give the lamina its uniform and exact thickneſs. Inſtead of dividing the lamina into ſmall ſquares, they at once cut clean out of it as many planchets as it can contain, by means of a ſharp ſteel trepan, of a roundiſh figure, hollow within, and of a proportionable diameter, to ſhape and cut off the piece at one and the ſame time. After theſe planchets have been prepared and weighed with ſtandard-pieces, filed or ſcraped to get off the ſuperfluous part of the metal, and then boiled and made clean, they arrive, at laſt, at the machine, (Plate LXVI. fig. 1.), which marks them upon the edge; and finally, the mill, (fig. 2.) which, ſqueezing each of them ſingly between the two dyes, brought near each other with one blow, forces the two ſurfaces or fields of the piece to fill exactly all the vacancies of the two figures engraved hollow. The engine which ſerves to laminate lead, gives a ſufficient notion of that which ſerves to flaten gold and ſilver laminæ between rollers of a leſſer ſize. See Laminating.

The principal pieces of the machine, (fig. 1.), to ſtamp coins on the edge, are two ſteel laminæ, about a line thick. One half of the legend, or of the ring, is engraved on the thickneſs of one of the laminæ, and the other half on the thickneſs of the other; and theſe two laminæ are ſtraight, although the planchet marked with them be circular.

When they ſtamp a planchet, they firſt put it between the laminæ in ſuch a manner, as that theſe being each of them laid flat upon a copper-plate, which is faſtened upon a very thick wooden table, and the planchet being likewiſe laid flat upon the ſame plate, the edge of the planchet may touch the two laminæ on each ſide, and in their thick part.

One of theſe laminæ is immoveable, and faſtened with

with feveral fcrews; the other flides by means of a dented wheel, which takes into the teeth that are on the furface of the lamina. This fliding lamina makes the planchet turn in fuch a manner, that it remains ftamped on the edge, when it has made one turn. Only crown and half-crown pieces can bear the impreffion of letters on the thicknefs of their edges.

The coining engine or mill is fo handy (fig. 2.) that a fingle man may ftamp twenty thoufand planchets in one day: gold, filver, and copper planchets, are all of them coined with a mill, to which the coining fquares, (fig. 3.), commonly called dyes, are faftened; that of the face under, in a fquare box garnifhed with male and female fcrews, to fix and keep it fteady; and the other above, in a little box garnifhed with the fame fcrews, to faften the coining fquare. The planchet is laid flat on the fquare of the effigy, which is dormant; and they immediately pull the bar of the mill by its cords, which caufes the fcrew fet within it to turn. This enters into the female fcrew, which is in the body of the mill, and turns with fo much ftrength, that by pufhing the upper fquare upon that of the effigy, the planchet, violently preffed between both fquares, receives the impreffion of both at one pull, and in the twinkling of an eye.

The planchet thus ftampt and coined, goes through a final examination of the mint wardens, from whofe hands it goes into the world.

In the Coining *of medals*, the procefs is the fame, in effect, with that of money; the principal difference confifting in this, that money having but a fmall relievo, receives its impreffion at a fingle ftroke of the engine; whereas for medals, the height of their relievo makes it neceffary that the ftroke be repeated feveral times: to this end the piece is taken out from between the dyes, heated, and returned again; which procefs in medallions and large medals, is repeated fifteen or twenty times before the full impreffion be given, care muft be taken, every time the planchet is removed, to take off the fuperfluous metal ftretched beyond the circumference with a file. Medallions, and medals of a high relievo, are ufually firft caft in fand, by reafon of the difficulty of ftamping them in the prefs, where they are put only to perfect them; in regard the fand does not leave them clear, fmooth, and accurate enough. Therefore we may fee that medals receive their form and impreffion by degrees, whereas money receives them all at once.

Britifh Coinage, both by the beauty of the engraving, and by the invention of the impreffions on the edges, that admirable expedient for preventing the alteration of the fpecies, is carried to the utmoft perfection.

It was only in the reign of king William III. that the hammer-money ceafed to be current in England, where till then it was ftruck in that manner, as in other nations. Before the hammer fpecies was called in, the Englifh money was in a wretched condition, having been filed and clipped by natives as well as foreigners, infomuch that it was fcarce left of half the value: the retrieving this diftreffed ftate of the Englifh money is looked upon as one of the glories of king William's reign.

The Britifh coinage is now wholly performed in the Tower of London, where there is a corporation for it, under the title of the mint. Formerly there were here, as there are ftill in other countries, the rights of feinorage and braffage: but fince the eighteenth year of king Charles the Second, there is nothing taken either for the king, or for the expences of coining; fo that weight is returned for weight, to any perfon who carries their gold and filver to the Tower.

The fpecies coined in Great Britain are efteemed contraband goods, and not to be exported. All foreign fpecies are allowed to be fent out of the realm, as well as gold and filver in bars, ingots, duft, *&c.*

Barbary Coinage, particularly that of Fez and Tunis, is under no proper regulations, as every goldfmith, Jew, or even private perfon, undertakes it at pleafure; which practice renders their money exceeding bad, and their commerce very unfafe.

Mufcovite Coinage. In Mufcovy there is no other coin ftruck but filver, and that only in the cities of Mufcow, Novogrod, Twere, and Plefkow, to which may be added Peterfburgh. The coinage of each of thefe cities is let out to farm, and makes part of the royal revenue.

Perfian Coinage. All the money made in Perfia is ftruck with a hammer, as is that of the reft of Afia; and the fame may be underftood of America, and the coafts of Africa, and even Mufcovy: the king's duty, in Perfia, is feven and a half *per cent.* for all the monies coined, which are lately reduced to filver and copper, there being no gold coin there, except a kind of medals, at the acceffion of a new fophi.

Spanifh Coinage is efteemed one of the leaft perfect in Europe. It is fettled at Seville and Segovia, the only cities where gold and filver are ftruck.

COIRE, or Chur, the capital of the country of the Grifons, in Switzerland, fituated on the river Rhine, fifty-three miles fouth of Conftance: E. long. 9° 25′, N. lat. 46° 40′.

COITION. See Generation.

COIX, or Job's tears, in botany, a genus of the monoecia triandria clafs. The calix of the male is a double-flowered glume, without any awn; the corolla is likewife a glume without an awn: the calix of the female is an open, oval, one-flowered glume; the ftylus is bifid; and the feed is cartilaginous. There is but one fpecies, *viz.* the latifolia, a native of Jamaica.

COKENHAUSEN, a fortrefs of Livonia, fituated on the river Dwina, about thirty-two miles eaft of Riga: E. long. 25°, N. lat. 57°.

COLATURE. See Filtration.

COLCHESTER, a large borough-town of Effex, fituated on the river Coln, twenty miles north-eaft of Chelmsford, on the road to Harwich: E. long. 1°, N. lat. 51° 55′. It fends two members to parliament.

COLCHICUM, or Meadow-saffron, in botany, a

genus of the hexandria trigynia claſs. The corolla is divided into ſix ſegments, and the tube is radicated; it has three inflated capſules united together. The ſpecies are three, only one of which, *viz.* the autumnale, or meadow-ſaffron, is a native of Britain.

COLD, in general, denotes the privation or abſence of heat; and, conſequently, thoſe who ſuppoſe heat to conſiſt in a briſk agitation of the component particles of the hot body, define cold to be ſuch a faint motion of theſe parts, as is either altogether or nearly imperceptible to our organs of feeling: in which ſenſe, cold is a mere term of relation between the cold body and the organs of ſenſation; and, in fact, the ſame body will be felt either hot or cold, according as the ſenſible organ is colder or hotter than it.

COLD, in medicine, is found to be productive of inflammatory diſorders, as coughs, pleuriſies, peripneumonies, rheumatic pains, conſumptions, &c. See MEDICINE.

COLDENIA, in botany, a genus of the tetrandria tetragynia claſs. The calix has four leaves; the corolla is tunnel-ſhaped; the fruit conſiſts of four ſeeds. There is but one ſpecies, a native of India.

COLD-FINCH. See MOTACILLA.

COLDSHIRE-IRON, that which is brittle when cold.

COLE-FISH. See GADUS.

COLE-MOUSE, in ornithology. See PARUS.

COLEOPTERA, the name of Linnæus's firſt order of inſects. The inſects belonging to this order have four wings; the upper pair, which ſerve as covers to the other two, are cruſtaceous, with a ſtraight ridge or ſuture in the middle. See NATURAL HISTORY.

COLE-SEED, the ſeed of the *napus ſativa*, or long-rooted, narrow-leaved rapa, called, in Engliſh, navew, and comprehended by Linnæus among the braſſicas, or cabbage-kind. See BRASSICA.

This plant is cultivated to great advantage in many parts of England, on account of the nape-oil expreſſed from its ſeeds. It requires a rich and ſtrong ſoil, eſpecially in march or fenny lands, thoſe newly recovered from the ſea, or indeed any other land that is rank and fat, whether arable or paſture. The beſt ſeeds are brought from Holland, and ſhould be ſown about Midſummer, the very day that the land is plowed: a gallon will ſerve an acre.

Beſides the oil already mentioned, it is likewiſe cultivated for winter-food to cattle, and is a very good preparative of land for barley or wheat.

COLE-WORT. See BRASSICA.

COLIAS, in ichthyology. See SCOMBER.

COLIC, in medicine, a ſevere pain in the lower venter, ſo called, becauſe the diſorder was formerly ſuppoſed to be ſeated in the colon. See MEDICINE.

COLIC-SHELL. See SYPROEA.

COLIR, an officer in China, who may properly be called an inſpector, having an eye over what paſſes in every court or tribunal of the empire.

In order to render him impartial, he is kept independent, by having poſt for life. The power of the colirs is ſuch, that they make even the princes of the blood tremble.

COLISEUM, in ancient architecture, an oval amphitheatre at Rome, built by Veſpaſian, wherein were ſtatues ſet up, repreſenting all the provinces of the empire: in the middle whereof ſtood that of Rome, holding a golden apple in her hand.

This ſtructure was ſo large, that it would hold near 100,000 ſpectators.

COLITES, in natural hiſtory, a name given by ſome writers to a kind of pebble, found in the ſhape of the human penis and teſtes, and that either ſeparately, or both together.

COLLAR, in Roman antiquity, a ſort of chain put generally round the neck of ſlaves that had run away, after they were taken, with an inſcription round it, intimating their being deſerters, and requiring their being reſtored to their proper owners, &c.

COLLAR, in a more modern ſenſe, an ornament conſiſting of a chain of gold, enamelled, frequently ſet with cyphers or other devices, with the badge of the order hanging at the bottom, wore by the knights of ſeveral military orders over their ſhoulders, on the mantle, and its figure drawn round their armories.

Thus, the collar of the order of the garter conſiſts of S S, with roſes enamelled red, within a garter enamelled blue, and the George at the bottom.

Lord Mayor's COLLAR is more uſually called chain.

Knights of the COLLAR, a military order in the republic of Venice, called alſo the order of St Mark, or the medal.

It is the doge and the ſenate that confer this order; the knights bear no particular habit, only the collar, which the doge puts around their neck, with a medal, wherein is repreſented the winged lion of the republic.

COLLAR *of a draught horſe*, a part of harneſs made of leather and canvas, and ſtuffed with ſtraw or wool, to be put about the horſe's neck.

COLLARAGE, a tax or fine laid for the collars of wine-drawing horſes.

COLLATERAL, any thing, place, country, &c. ſituated by the ſide of another.

COLLATERAL, in genealogy, thoſe relations which proceed from the ſame ſtock, but not in the ſame line of aſcendants or deſcendants, but being, as it were, aſide of each other.

Thus, uncles, aunts, nephews, nieces and couſins, are collaterals, or in the ſame collateral line: thoſe in a higher degree, and nearer the common root, repreſent a kind of paternity with regard to thoſe more remote.

COLLATERAL *ſucceſſion*, in Scots law: When a defunct, for want of heirs deſcended of himſelf, is ſucceeded in his eſtate by a brother or ſiſter, or their deſcendents, the eſtate is ſaid to have gone to *collateral heirs*. See SCOTS LAW, title, *Succeſſion in heretable rights*.

COLLATION, in the canon law, the giving or beſtowing of a benefice on a clergyman by a biſhop, who has it in his own gift or patronage.

COLLATION, in common law, the compariſon or preſentation of a copy to its original, to ſee whether or not it be conformable; or the report or act of the officer

ficer who made the comparifon. A collated act is equivalent to its original, provided all the parties concerned were prefent at the collation.

COLLATION, in Scots law, that right which an heir has of throwing the whole heritable and moveable eftates of the deceafed into one mafs, and fharing it equally with the others in the fame degree of kindred, when he thinks fuch fhare will be more than the value of the heritage to which he had an exclufive title. See SCOTS LAW, title, *Succeffion in moveables*.

COLLATION is alfo vulgarly ufed for a repaft between dinner and fupper.

COLLEAGUE, a partner or affociate in the fame office or magiftrature. See ADJUNCT.

COLLECTS, in an ecclefiaftical fenfe, the fhort prayers into which the public devotions of the church are divided.

In the primitive church, the collects were repeated by the bifhop alone, after the joint prayers of the deacon and congregation.

COLLECTIVE, among grammarians, a term applied to a noun expreffing a multitude, though itfelf be only fingular; as an army, company, troop, *&c.* called collective nouns.

COLLECTOR, in general, denotes a perfon who gets or brings together things formerly difperfed and feparated. Hence,

COLLECTOR, in matters of civil polity, is a perfon appointed by the commiffioners of any duty, the inhabitants of a parifh, *&c.* to raife or gather any kind of tax.

COLLECTOR, among botanifts, one who gets together as many plants as he can, without ftudying botany in a fcientifical manner.

COLLEGATORY, in the civil law, a perfon who has a legacy left him in common with one or more other perfons.

COLLEGE, an affemblage of feveral bodies or focieties, or of feveral perfons into one fociety.

College, among the Romans, ferved indifferently for thofe employed in the offices of religion, of government, the liberal, and even mechanical arts and trades; fo that, with them, the word fignified what we call a corporation or company.

Each of thefe colleges had diftinct meeting-places or halls; and likewife, in imitation of the ftate, a treafury and common cheft, a regifter, and one to reprefent them upon public occafions, and acts of government. Thefe colleges had the privilege of manumitting flaves, of being legates, and making by-laws for their own body, provided they did not clafh with thofe of the government.

There are various colleges on foot among the moderns, founded on the model of thofe of the ancients. Such are the three colleges of the empire, *viz.*

COLLEGE *of electors, or their deputies*, affembled in the diet of Ratifbon.

COLLEGE *of princes*, the body of princes, or their deputies, at the diet of Ratifbon.

COLLEGE *of cities*, is, in like manner, the body of deputies which the imperial cities fend to the diet.

COLLEGE *of cardinals*, or the *facred* COLLEGE, a body compofed of the three orders of cardinals. See CARDINALS.

COLLEGE is alfo ufed for a public place endowed with certain revenues, where the feveral parts of learning are taught.

An affemblage of feveral of thefe colleges conftitute an univerfity. The erection of colleges is part of the royal prerogative, and not to be done without the king's licenfe. See UNIVERSITY.

COLLEGE *of civilians*, commonly called *Doctors-commons*, founded by Dr Harvey, dean of the arches, for the profeffors of the civil law refiding in the city of London. The judges of the arches, admiralty, and prerogative court, with feveral other eminent civilians, commonly refide here.

To this college belong thirty-four proctors, who make themfelves parties for their clients, manage their caufes, give licenfes for marriages, *&c.*

In the common hall of Doctors-commons are held feveral courts, under the jurifdiction of the civil law, particularly the high court of admiralty, the court of delegates, the arches court of Canterbury, and the prerogative court of Canterbury, whofe terms for fitting are much like thofe at Weftminfter, every one of them holding feveral court-days; moft of them fixed and known by preceding holidays, and the reft appointed at the judge's pleafure.

COLLEGE *of phyficians*, a corporation of phyficians in London, whofe number, by charter, is not to exceed eighty. The chief of them are called fellows, and the next candidates, who fill up the places of fellows as they become vacant by death, or otherwife. Next to thefe are the honorary fellows; and laftly, the licentiates, that is, fuch as being found capable, upon examination, are allowed to practife phyfic.

This college has feveral great privileges granted by charter and acts of parliament. No man can practife phyfic in, or within feven miles of London, without licenfe of the college, under the penalty of 5 *l.* Alfo, perfons practifing phyfic in other parts of England are to have letters teftimonial from the prefident and three elects, unlefs they be graduate phyficians of Oxford or Cambridge. Every member of the college is authorifed to practife furgery in London or elfewhere; and that they may be able at all times to attend their patients, they are freed from all parifh-offices.

The college is governed by a prefident, four cenfors, and twelve electors. The cenfors have, by charter, power to furvey, govern, and arreft all phyficians, or others, practifing phyfic in or within feven miles of London; to fine, amerce, and imprifon them at difcretion; to fearch apothecaries fhops, *&c.* in and about London; to fee if their drugs, *&c.* be wholefome, and the compofitions according to the form prefcribed by the college in their difpenfaries; and to burn, or otherwife deftroy, thofe that are defective or decayed, and not fit for ufe.

In 1696, forty-two members of the college made a fubfcription, to fet on foot a difpenfary for the relief of the fick poor, who are advifed gratis every day but Sunday,

Sunday, and medicines ſold at the intrinſic value: ſince this they have erected two other diſpenſaries.

COLLEGE *of juſtice*, in Scots law, the ſupreme civil court of Scotland; otherwiſe called *Court of ſeſſion*, or, *of council and ſeſſion*. See SCOTS LAW, title; *Supreme judges and courts of Scotland*.

Sion COLLEGE, or the college of the London clergy, was formerly a religions houſe, next to a ſpittal or hoſpital; and now it is a compoſition of both, *viz.* a college for the clergy of London, who were incorporated in 1631, at the requeſt of Dr White, under the name of the preſident and fellows of Sion-college; and an hoſpital of ten poor men, the firſt within the gates of the houſe, and the latter without.

This college conſiſts of a preſident, two deans, and four aſſiſtants, who are annually choſen from among the rectors and vicars in London, ſubject to the viſitation of the biſhop. They have one of the fineſt libraries in England, built and ſtocked by Mr Simpſon, chiefly for the clergy of the city, without excluding other ſtudents on certain terms; they have alſo a hall with chambers for the ſtudents, generally filled with the miniſters of the neighbouring pariſhes.

Greſham-COLLEGE, or COLLEGE *of philoſophy*, a college founded by Sir Thomas Greſham, who built the Royal-exchange; a moiety of the revenue whereof he gave in truſt to the mayor and commonalty of London, and their ſucceſſors for ever, and the other moiety to the company of mercers; the firſt to find four able perſons to read in the college divinity, aſtronomy, muſic, and geometry; and the laſt, three or more able men to read rhetoric, civil law, and phyſic; a lecture upon each ſubject is to be read in term-time, every day, except Sundays, in Latin, in the forenoon, and the ſame in Engliſh in the afternoon; only the muſic-lecture is to be read alone in Engliſh. The lecturers have each 50 *l. per annum*, and a lodging in the college.

In this college formerly met the royal ſociety, that noble academy, celebrated throughout the world for their improvements in natural knowledge. See SOCIETY.

COLLEGE *of heralds*, commonly called the *heralds office*, a corporation founded by charter of king Richard III. who granted them ſeveral privileges, as to be free from ſubſidies, tolls, offices, *&c.* They had a ſecond charter from king Henry VI.; and a houſe built near Doctors-commons, by the earl of Derby, in the reign of king Henry VII. was given them by the duke of Norfolk, in the reign of queen Mary, which houſe is now rebuilt.

This college is ſubordinate to the earl-marſhal of England. They are aſſiſtants to him in his court of chivalry, uſually held in the common hall of the college, where they ſit in their rich coats of his majeſty's arms. See HERALD.

COLLEGIATE *churches*, thoſe which though no biſhop's ſee, yet have the retinue of the biſhop, the canons and prebends. Such are, among us, Weſtminſter, Windſor, Rippon, Wolverhampton, Southwell, Mancheſter, *&c.* governed by deans and chapters.

COLLET, among jewelers, denotes the horizontal face or plane at the bottom of brilliants. See BRILLIANT.

COLLET, in glaſs-making, is that part of glaſs veſſels which ſticks to the iron inſtrument wherewith the metal was taken out of the melting-pot: theſe are afterwards uſed for making green glaſs.

COLLETICS, in pharmacy, denote much the ſame with agglutinants or vulneraries. See VULNERARY.

COLLINSONIA, in botany, a genus of the decandria monogynia claſs. The corolla is unequal, the inferior lip being multifid and capillary. It has but one ſeed. There is only one ſpecies, a native of Canada.

COLLIQUAMENTUM, in natural hiſtory, an extreme tranſparent fluid in an egg, obſervable after two or three days incubation, containing the firſt rudiments of the chick. It is included in one of its own proper membranes, diſtinct from the albumen. Harvey calls it the oculus.

COLLIQUATION, in chemiſtry, is applied to animal, vegetable, and mineral ſubſtances, tending towards fuſion. See FUSION.

COLLIQUATION, in phyſic, a term applied to the blood, when it loſes its craſis or balſamic texture; and to the ſolid parts, when they waſte away, by means of the animal fluids flowing off through the ſeveral glands, and particularly thoſe of the ſkin, faſter than they ought: which occaſions fluxes of many kinds, but moſtly profuſe, greaſy, and clammy ſweats.

COLLIQUATIVE *fever*, in phyſic, a fever attended with a diarrhœa, or profuſe ſweats.

COLLISION, the ſtriking of one hard body againſt another; or the friction or percuſſion of bodies moving violently with different directions, and daſhing againſt each other. See MECHANICS.

COLLURIO, in ornithology. See LANIUS.

COLLUSION, in law, a ſecret underſtanding between two parties, who plead or proceed fradulently againſt each, to the prejudice of a third perſon.

COLLUM, the ſame with neck. See NECK, and CERVIX.

COLLYRIUM, in pharmacy, a topical remedy for a diſorder of the eyes; deſigned to cool and repel hot, ſharp humours.

They are generally of two kinds, the one liquid, and the other dry: liquid collyrias are compoſed of ophthalmic powders in waters, as roſe-water, plantain-water, or that of fennel, eye-bright, *&c.* wherein tutty, white vitriol, or ſome other proper powder, is diſſolved.

The dry collyrium is troches of rhaſis, ſugar-candy, tutty prepared, *&c.* blown into the eye.

COLOCASIA, in botany. See ARUM.

COLOCYNTHIS, in botany. See CUCUMIS.

COLOGNE, the capital of the circle of the Lower Rhine, in Germany, ſituated on the Rhine, about forty-five miles eaſt of Mæſtricht; E. long. 6° 40′, N. lat. 50° 50′. It is one of the largeſt and moſt elegant cities of Germany, being the ſee of an archbiſhop, who is one of the electors of the empire, and has a yearly revenue of 130,000 *l.*

COLOGNE-

COLOGNE-*earth*, a kind of very light baſtard ochre, of a deep brown colour.

COLON, in anatomy. See Vol. I. p. 261.

COLON, in grammar, a point or character marked thus, (:), ſhewing the preceding ſentence to be perfect or entire; only that ſome remark, farther illuſtration, or other matter connected therewith, is ſubjoined.

COLONEL, in military matters, the commander in chief of a regiment, whether horſe, foot, or dragoons.

A colonel may lay any officer of his regiment in arreſt, but muſt acquaint the general with it; he is not allowed a guard, only a centry from the quarter-guard.

COLONEL-*lieutenant*, he who commands a regiment of guards, whereof the king, prince, or other perſon of the firſt eminence, is colonel. Theſe colonel-lieutenants have always a colonel's commiſſion, and are uſually general officers.

Lieutenant-COLONEL, the ſecond officer in a regiment, who is at the head of the captains, and commands in the abſence of the colonel.

COLONNA, a town of Italy, in the Campagna of Rome, eighteen miles eaſtward of that city: E. long. 13° 15′, N. lat. 42°.

COLONNADE, in architecture, a periſtyle of a circular figure; or a ſeries of columns diſpoſed in a circle, and inſulated within ſide.

A polyſtile COLONNADE, is that whoſe numbers of columns is too great to be taken in by the eye at a ſingle view. Such is the colonnade of the palace of St Peter's at Rome, conſiſting of 284 columns of the Doric order, each above four foot and an half diameter, all in Tiburtine marble.

COLONY, a company of people tranſplanted into a remote province, in order to cultivate and inhabit it.

Colonies are of three ſorts: the firſt are thoſe that ſerve to eaſe and diſcharge the inhabitants of a country, where the people are become too numerous; the ſecond are thoſe eſtabliſhed by victorious princes in the middle of vanquiſhed nations, to keep them in awe and obedience; and the third ſort are thoſe eſtabliſhed for the promotion of trade, called colonies of commerce; ſuch are thoſe eſtabliſhed by European nations in ſeveral parts of Aſia, Africa, and America.

COLOPHONY, in pharmacy, black reſin, or turpentine, boiled in water, and afterwards dried; or, which is ſtill better, the caput mortuum remaining after the diſtillation of the etherial oil, being further urged by a more intenſe and long continued fire.

COLOQUINTIDA, in botany. See CUCUMIS.

COLORATURA, in muſic, denotes all manner of variations, trillos, diminutions, &c. ſerving to make a ſong agreeable.

COLOSSUS, a ſtatue of a gigantic, or enormous ſize.

The moſt famous of this kind was the coloſſus of Rhodes, made, in honour of Apollo, by Chares the diſciple of Lyſippus. It was eighty-ſix feet high, and its thumb ſo large, that few people could fathom it. This ſtatue was placed acroſs the mouth of the harbour at Rhodes, and the ſhips with full ſails paſſed betwixt its legs.

COLOSTRUM, the firſt milk of any animal after bringing forth young, called beeſtings. It is remarkable that this milk is generally cathartic, and purges off the meconium; thus ſerving both as an aliment and medicine.

An emulſion prepared with turpentine, diſſolved with the yolk of an egg, is ſometimes called by this name.

COLOUR. See OPTICS.

COLOUR, in painting, is applied both to the drugs, and to the tints produced by thoſe drugs variouſly mixed and applied.

The principal colours uſed by painters are red and white lead, or ceruſs; yellow and red ochres; ſeveral kinds of earth, umbre, orpiment, lamp-black, burnt ivory, black lead, cinnabar or vermillion, gumboge, lacca, blue and green aſhes, verdigris, biſtre, bicce, ſmalt, carmine, ultra marine: each of which, with their uſes, &c. are to be found under their proper articles.

Of theſe colours ſome are uſed tempered with gum-water, ſome ground with oil, others only in freſco, and others for miniature.

Painters reduce all the colours they uſe under theſe two claſſes, of dark and light colours: dark colours are black, and all others that are obſcure and earthy, as umbre, biſtre, &c.

Under light colours are comprehended white, and all that approach neareſt to it.

Painters alſo diſtinguiſh colours into ſimple and mineral.

Under ſimple colours they rank all thoſe which are extracted from vegetables, and which will not bear the fire; as the yellow, made of ſaffron, French berries, lacca, and other tinctures extracted from flowers, uſed by limners, illuminers, &c.

The mineral colours are thoſe which being drawn from metals, &c. are able to bear the fire, and therefore uſed by enamellers. Changeable and permanent colours is another diviſion, which, by ſome, is made of colours.

Changeable colours are ſuch as depend on the ſituation of the objects with reſpect to the eye, as that of a pigeon's neck, taffeties, &c. the firſt however being attentively viewed by the microſcope, each fibre of the feathers appears compoſed of ſeveral little ſquares, alternately red and green, ſo that they are fixed colours.

Local COLOURS. See LOCAL.

Water COLOURS. See WATER.

COLOUR, in dying. There are, in the art of dying, five colours, called ſimple, primary, or mother colours, from the mixture of which all other colours are formed; theſe are blue, yellow, brown, red, and black. Of theſe colours, variouſly mixed and combined, they form the following colours, panſy, blue, and red; from the mixture of blue and ſcarlet are formed amaranth, violet, and panſy; from the ſame mixture of blue, crimſon, and red, are formed the columbine, or dove-colour, purple-crimſon, amaranth, panſy, and crimſon-violet. See BOTANY, Vol. I. p. 633.

Here it is to be obſerved, that they give the name crimſon to all colours made with cochineal.

Colour, in heraldry. The colours generally uſed in heraldry are red, blue, black, green, and purple, which the heralds call gules, azure, ſable, vert or ſinople, and purpure; tenne or tawny, and ſanguine, are not ſo common: as to yellow and white, called *or* and *argent*, they are metals, not colours.

The metals and colours are ſometimes expreſſed in blazon by the names of precious ſtones, and ſometimes by thoſe of planets or ſtars. See Blazoning.

Oenomaus is ſaid to have firſt invented the diſtinction of colours, to diſtinguiſh the gundillæ of combatants of the Circenſian games; the green for thoſe who repreſented the earth, and blue for thoſe who repreſented the ſea.

Colours, in the military art, include the banners, flags, enſigns, &c. of all kinds, borne in the army or fleet. See Flag, and Standard.

Field-Colour. See Field.

Colours, in the Latin and Greek churches, are uſed to diſtinguiſh ſeveral myſteries and feaſts, celebrated therein.

Five colours only are regularly admitted into the Latin church; theſe are white, green, red, violet, and black: the white is for the myſteries of our Saviour, the feaſts of the virgin, thoſe of the angels, ſaints, and confeſſors; the red is for the myſteries and ſolemnities of the holy ſacrament, the feaſts of the apoſtles and martyrs; the green for the time between pentecoſt and advent, and from epiphany to ſeptuageſima; the violet in advent and Chriſtmas, in vigils, rogations, &c. and in votive maſſes in time of war; laſtly, the black is for the dead, and the ceremonies thereto belonging.

In the Greek church, the uſe of colours is almoſt aboliſhed, as well as among us: red was, in the Greek church, the colour for Chriſtmas, and the dead, as black among us.

To Colour *ſtrangers goods*, is when a freeman allows a foreigner to enter goods at the cuſtom-houſe in his name.

COLOURING, among painters, the manner of applying and conducting the colours of a picture; or the mixtures of light and ſhadows, formed by the various colours employed in painting. See Painting.

Colouring *of glaſs*. See Glass.

Colouring *of porcelain*. See Porcelain.

COLT, in zoology. See Equus.

Colt-evil, among farriers, a ſwelling of the yard and ſcrotum, incident both to ſtoned horſes and geldings; for which, after waſhing the part with lukewarm vinegar, it is uſual to anoint them with juice of rue, mixed with honey, and boiled in hog's greaſe, adding bay-leaves and the powder of fenugreek.

Colt's-foot, in botany. See Tussilago.

COLTIE, a term uſed by timber-merchants for a defect, or blemiſh, in ſome of the annular circles of a tree, whereby its value is much diminiſhed.

COLUBER, in zoology, a genus of ſerpents belonging to the claſs of amphibia. The characters are theſe: They have a number of ſcuta, or hard cruſts, on the belly; and ſcutellæ, or ſcales, on the tail. Linnæus enumerates no leſs than 97 ſpecies under this genus, diſtinguiſhed ſolely by the number of ſcuta and ſcutellæ. For the ſake of brevity, we ſhall give the numbers in figures, the firſt denoting the number of ſcuta, and the ſecond the number of ſcutellæ, thus, 140-22.

The firſt ſpecies is the vipera, 118-22. This is the viper of the ſhops, the fleſh of which has been much recommended in ſcrophulous, leprous, and other obſtinate chronical diſorders: but its virtues in theſe caſes have been too much exaggerated: the fleſh of the viper is however highly nutritive, and is therefore properly eſteemed to be a good reſtorative: but, to anſwer any good purpoſe, even when given with this intention, it ought to be uſed liberally, and for a conſiderable time, as food. This animal is a native of Egypt. The body is very ſhort, and of a pale colour, with browniſh ſpots; and the head is gibbous, and covered with ſmall ſcales. 2. The atropos, 131-22, is a native of America; the body is white, and the eyes are brown, with a white iris. 3. The leberis, 110-50, is a native of Canada, and has many linear black rings. 4. The ammodites, 142-32, is about ſix inches long, and has an erect fleſhy protuberance on its noſe. It is a native of the Eaſt. 5. The berus, 146-39, or common Britiſh viper, is found in moſt countries in Europe: It is of a duſky blackiſh colour. 6. The cherſea, 150-34, is a native of Sweden, and rather leſs than the aſp. 7. The preſter, 152-32, is found in the northern parts of Europe, and the whole body is black. 8. The aſpis, 146-46, is a native of France, and is of a reddiſh colour, with duſky ſpots on the back. 9. Lebetinus, 155-46, is a native of Aſia, and is of a cloudy colour, with red ſpots on the belly. 10. The ſeverus, 170-42, is likewiſe a native of Aſia, and is aſh-coloured, with white belts. 11. The ſtolatus, 143-76, is a native of Aſia, and is of a greyiſh colour, with two white fillets. 12. The lacteus, 203-32, is a native of the Indies; the colour is white, with black ſpots. 13. The naja, 193-60, is a native of the Eaſt Indies; and is the moſt poiſonous of all ſerpents; they are eat by the ichneumon. 14. The atrox, 196-69, is a native of Aſia; it is of a hoary colour; and the head is compreſſed and covered with ſmall ſcales. 15. The niveus, 209-62, is white, without any ſpots. It is a native of Africa. 16. The corallinus, 193-82, is a native of Aſia: It is greyiſh, with three brown fillets. 17. The dipſas, 152-135, is a native of America: it is of a blueiſh colour, with the margins of the ſcales white. 18. The mycterizans, 192-167, is a native of America; the ſnout is ſtretched out, and triangular. Although this genus comprehends 97 ſpecies, the above 18 are all whoſe bite is ſuppoſed to be poiſonous. The poiſon is contained in a little bag at the baſe of their long fangs. See Natural History.

The 19th ſpecies is the lutrix, 134-27; the back and belly are yellow; and the ſides are blueiſh. It is a native of the Indies. 20, The calamarius, 140-22, is of a livid colour interſperſed with duſky ſpots and

and lines, and is found in America. 21. The fimus, 124-46, is a native of Carolina; the head is roundifh, flat, and gibbous; the body is interfperfed above with black and white; and the belly is black. 22. The ftriatulus, 126 45, is likewife a native of Carolina: the back is dufky and ftriated; and the belly is pale. 23. The ceraftes, 150-25, is a native of Afia; the fcales of the head are round and fmall: this is the horned viper of Haffelquift; but the horns are a mere impofition; the Arabians fix the fpurs of a cock or other bird upon the head of the viper, in order to raife the admiration of travellers. 24. The plicatilis, 131-46, is of a livid colour, with dufky fides. 25. The domicella, 118-60, is a native of Afia; it is white, with black belts. 26. The alidras, 121-58, is a native of India, and is all white. 27. The punctatus, 136-43, is a native Carolina: It is afh-coloured, variegated with yellow fpots. 28. The buccatus, 107-72, is dufky-coloured, with white belts, and is a native of Afia. 29. The angulatus 117-70, is a native of Afia, and of a greyifh colour, with black fillets. 30. The cæruleus, 165-24, is blueifh, with white fcales on one fide: It is a native of America. 31. The albus, 170-20, is entirely white, and is a native of Afia. 32. The typhlus, 140-53, is a native of the Indies, and of a blueifh colour. 33. The fafciatus, 128-67, is a native of Carolina; the fcales are carinated, and the colour is blackifh. 34. The melanocephalus, 140 62, is a native of America; the body is very fmooth; the colour is dufky, and the head is black. 35. The cobella, 150-54, is very frequent in America: it is afh-coloured, interfperfed with white lines. 36. The reginæ, 137-70, is a native of the Indies; the body is dufky, and the belly is black and white. 37. The dollatus, 164-43, is a native of Carolina; this is a fmall ferpent, of a whitifh colour, with black rings. 38. The ordinatus, 138-72, is likewife found in Carolina: It is blueifh, and clouded with black fpots. 39. The Mexicanus, 134-77, is a native of America. 40. The aurora, 179 37, is a native of America: it is livid, with a yellow back. 41. The fipedon, 144-73, is yellowifh, and a native of North America. 42. The maurus, 152-66, is a native of Algiers: the body is yellowifh above, and the belly is red. 43. The vittatus, 142-78, is a native of America; the edges of the fcales are yellowifh, and there is a white dentated fillet under the anus. 44. The miliaris, 162-59, is a native of the Indies: the body is yellow, with a white fpot in each fcale; and the belly is white. 45. The æfculapii, 180-43, is a native of the Indies: it has white and black belts. 46. The rhombeatus, 157-70, is a native of the Indies: the colour is blueifh, with black fpots. 47. The cyaneus, 119-110, is a native of America: it is of an azure colour, and the belly is green. 48. The natrix, 170 60, is a native of Europe: it is black, with a white fpot on each fide of the neck. 49. The agilis, 184-50, is a native of the Indies: it has yellow and white belts. 50. The jaculatrix, 163-77, is a native of Surinam. 51. The aulicus, 184-60, is a native of America, and is of a greyifh colour, with white belts. 52. The monilis, 164-82, is a native America; the body is annulated, with three white fpots on the collar. 53. The fulvius, 218-31, is a native of Carolina: it has 22 black rings, and as many yellow, placed alternately. 54. The pallidus, 156-96, is a native of the Indies, and is of a pale colour, with grey and yellow fpots. 55. The lineatus, 169-84, is a native of Afia: it is blueifh, with four linear fillets. 56. The padera, 198 56, is a native of the Indies: it is white, with yellowifh fpots. 57. The canus, 188-70, is a native of the Indies: it is of a hoary colour, with yellowifh belts. 58. The getulus, 215 44, is a native of Carolina: it is of a blackifh blue colour, with yellow linear belts. 59. The fibilans, 160-100, is a native of Afia; and is blue, with black fillets, and a white belly. 60. The laticaudatus, 220-42, is a native of the Indies: it is afh-coloured, with yellow belts; and the tail is obtufe and compreffed. 61. The firtalis, 150 114, is a native of Canada: the body is of a dirty yellow colour, with three blueifh green fillets. 62. The fibon, 180-85, is a native of Africa: it is of a yellowifh iron-colour, interfperfed with white; and the belly is white, with yellow fpots. 68. The nebulatus, 185-81, is a native of America: it is clouded with yellow and an afh colour, and the belly is variegated with yellow and white. 64. The fufcus, 149-117, is a native of Afia; it is yellow and afh-coloured, and there are yellow fpots behind the eyes. 65. The faturninus, 147-120, is a native of the Indies: it is livid and coloured with an afh-colour, and the eyes are very large. 66. The candidus, 220-50, is a native of the Indies: it is white, with yellow belts. 67. The fcaber, 228-44, is a native of the Indies: it is clouded with black and yellow, and the fcales are carinated. 68. The carinatus, 157-115, is a native of the Indies: it is of a lead colour, and the edges of the fcales are tipped with white; the belly is white, and the back is carinated. 69. The ovivorus, 203 73, is a native of America. 70. The faurita, 156-121, is a native of Carolina: it is of a greenifh colour. 71. The conftrictor, 186 92, is a native of North America: it is black and fmooth; the belly is of a palifh green; and the nape of the neck is white. This fpecies is fo bold, that it even attacks men, twifting about their legs, and breaking their bones: it runs very quickly; but its bite is not poifonous. 72. The exoletus, 147-132, is a native of the Indies. It is blueifh and afh-coloured. 73. The fitula, 236-45, is a native of Egypt: It is greyifh. 74. The trifcalis, 195-86, is a native of the Indies: It is of an azure colour. 75. The guttatus, 227-60, is a native of Carolina: It is of a livid colour, with red and black fpots on the back. 76. The lemnifcatus, 250-35, is a native of Afia: The body is very fmooth, and variegated with white and black rings. 77. The annulatus, 190-96, is a native of America: It is white, with round yellow fpots. 78. The pelias, 187-103, is a native of the Indies: It is yellow behind the eyes, and the reft is blackifh. 79. The tyria, 210-83, is a native of Egypt: It is whitifh, with yellow fpots. 80. The jugularis, 195-102, is a native

tive of Egypt: It is black, with a red neck. 81. The pethola, 209-90, is a native of Africa: It is of a leaden colour. 82. The æſtivus, 155-144, is a native of Carolina: It is blue, and very ſmooth; and the belly is of a paliſh green. 83. The molurus, 248 59, is a native of the Indies: This ſpecies is very like the boa; but the ſcuta and ſcales are larger. 84. The ahætulla, 163-150, is a native of Aſia and America: It is of a yellowiſh green colour, and the tops of the ſcales are black; it has likewiſe a black belt acroſs the eyes. 85. The petalarius, 212-102, is a native of the Indies: It is yellow, with white belts. 86. The haje, 207-109, is a native of Egypt. This is a large ſerpent, with oblique red belts, and about one half of each ſcale white. 87. The filiformis, 165-158, is a native of the Indies: It is black, with a white belly; and the head is thicker than the body. 88. The pullatus, 217-108, is a native of Aſia: It has red belts, with white ſpots. 89. The hippocrepis, 282-94, is a native of America: It is of a livid colour, with yellow ſpots. 90. The minervæ, 238-90, is a native of the Indies: It is of an azure colour, with a yellow fillet on the back. 91. The cinereus, 200-137, is a native of the Indies: It is of an aſh-colour, with a white belly. 92. The viridiſſimus, 217-122, is a native of Surinam: It is of a fine green colour. 93. The mucoſus, 200-140, is a native of the Indies: the head is blueiſh. 94. The domeſticus, 245-94, frequents the dwelling-houſes of Barbary: It greatly reſembles the hippocrepis. 95. The cenchoa, 220-124, is a native of America: It is yellowiſh, with pale ſpots and white belts: The head is globular. 96. The cæruleſcens, 215-170, is a native of the Indies, and is of an azure colour. 97. The argus, is a native of Africa; but hitherto we have had no juſt deſcription of it.—For the inſtincts, manner of living, *&c.* of ſerpents in general, ſee NATURAL HISTORY.

COLUBRINUM LIGNUM, or SNAKE-WOOD. See STRYCHNOS.

COLUMBA, PIGEON, in ornithology, a genus belonging to the order of paſſeres. The characters of this genus are theſe: The bill is ſtrait, and deſcends towards the point; the noſtrils are oblong, and half covered with a ſoft tumid membrane; and the tongue is entire, *i. e.* not cloven. There are 40 ſpecies, *viz.* 1. The œnas, or domeſtic pigeon, is blueiſh, with a greeniſh ſhining neck; on the back, towards the tail, it is white, with a blackiſh ſtreak on the point of the wings and tail. It is the ſtock-dove or wood-pigeon of Ray, and is a bird of Europe. The pigeon lays two eggs, and hatches them every month, for eight or nine months in the year, which, in the ſpace of four years, amounts to about 18000 deſcendants. They always bill before copulation: Their method of feeding their young is curious; they firſt macerate peaſe or other grain for ſome time in their crop, and then vomit it up into the mouths of the young ones. The male and female ſit upon their eggs by turns. 2. The hiſpanica, with white mealy wax on the bill. It is about double the ſize of the common pigeon. 3. The daſypus, with rough feathered legs. 4. The gutturoſa, or cropper, has a power of inflating its crop till it be as large as the animal's body. It is a native of Arabia Felix. 5. The cucullata has the feathers on the back-part of the head erect and reflected; and the bill is ſhort. 6. The hiſpida, or rough pigeon, with the ſmall feathers of the back and wings erected. It is a native of the Eaſt Indies. 7. The turbita, with the feathers on the breaſt bent backward, a ſhort bill, and a plain vertex. 8. The laticauda, or broad-tailed pigeon, has an erect open tail conſiſting of many feathers. 9. The gyratrix turns itſelf round when flying: it is a little leſs than the common pigeon. 10. The galeata, with the head and prime feathers of the wings and tail of the ſame colour, and always different from the reſt of the body. 11. The turcica, with red papillous wax. It is a bird of Arabia. 12. The tabellaria has naked eye-brows, and broad, white, fleſhy wax on the bill. Although this bird be carried to a very great diſtance from home, it returns with vaſt ſpeed; and hence the ancients employed it for the purpoſe of conveying back letters. 13. The montana has naked red orbits, a reddiſh body, and a yellow belly; the bill and feet are red. It is the mountain-partridge of Ray, and is a native of Jamaica. 14. The leucocephala, with the top of the head and the orbits red, and a blueiſh body. It is a native of North America. 15. The leucoptera, with naked blue orbits, and the prime wing-feathers white at the points, and the intermediate ones yellowiſh. It is the Indian turtle of Edwards, and is a native of Aſia. 16. The guinea, with naked red orbits, a yellowiſh bill, triangular white ſpots on the wings, and the prime wing-feathers black at the points. It is a native of Africa. 17. The coronata has black orbits, a large erect creſt on the head, and a blueiſh body. It is almoſt as large as a peacock, and is a native of Banda. 18. The ſtriata, with hoary orbits, and the body variegated with black and aſh-coloured belts. It is a native of the Eaſt Indies. 19. The palumbus, with the prime tail-feathers red behind, the prime wing-feathers edged with white, a white neck, and feathered legs. It is a native of Europe and Aſia. 20. The cyanocephala, with a blue head, and a white belt below the eye. It is a native of America. 21. The madagaſcarenſis, with feathered legs, a violet tail, a greeniſh blue body, and the beak and feet red. It is found in Madagaſcar. 22. The aenea, with feathered legs, greeniſh legs and bill, and a braſs-coloured body. It is a native of the Molucca Iſles. 23. The viridis, with a braſs-coloured body, a violet belly, and red legs half covered with feathers. It is found at Amboina. 24. The martinica, with a violet body, a yellowiſh belly, and the prime wing-feathers red on the inſide. It is found in Martinico. 25. The jamaicenſis, with blueiſh prime tail-feathers terminated by a white line. It is found in Jamaica. 26. The Senegalenſis, with the three outmoſt prime tail-feathers white, and the neck ſpotted with black. It is found in Senegal. 27. The nicobarica has a white tail, a black body, blue prime wing-feathers, a green-

iſh

ifh fhining back, and long feathers on the neck. It is found in the ifland of Nicombar near Pegu. 28. The finica is yellowifh, and belted with black; the belly is reddifh, the wings yellow, the prime wing-feathers black, and a black bill. It is a native of China. 29. The indica, with a purple body, green fhoulders, and the top of the head blueifh. It is a native of the Eaft Indies. 30. The canadenfis, with the prime wing-feathers yellow at the points, and the prime tail-feathers afh-coloured. It is a native of Canada. 31. The afra, with the exterior prime tail-feathers white at the points, and violet fpots on the wing-feathers. It is a native of Senegal. 32. The turtur, with the prime tail-feathers white, a greyifh back, and a flefh-coloured breaft. It is a native of India. 33. The riforia is clay-coloured above, and has a black crefcent on the neck. It is a native of India. 34. The poffyrina, with a purple body, and a yellow bill and legs. It inhabits America within the tropics. 35. The minuta is the fmalleft of all pigeons, is of a dufky colour, with five fteel-coloured fpots on the wings, and the outmoft prime tail-feathers white. It is a native of America. 36. The migratoria has a wedge-fhaped tail, red naked orbits, and a reddifh breaft. This fpecies is very frequent in North America: They live upon the feeds of the elm, oak, wheat, *&c.* and they winter in Carolina. 37. The carolinenfis has a wedge-fhaped tail, blue orbits, and a reddifh belly. It is a native of America. 38. The amboinenfis has a wedge-fhaped tail, a reddifh body, and a greenifh neck. It is found at Amboina. 39. The capenfis has a wedge-fhaped tail, and the prime wing-feathers red on the interior fide. It is found at the Cape of Good Hope. 40. The marginata has a wedge-fhaped tail, a red breaft, and the points of the prime tail-feathers black and edged with white.

COLUMBINE, in botany. See AQUILEGIA.

Feathered COLUMBINE. See THALICTRUM.

COLUMBUS, or *Congregation of St* COLUMBUS, a fociety of regular canons, who formerly had an hundred abbeys or monafteries in the Britifh iflands.

COLUMELLA, in botany. See Vol. I. p. 637.

COLUMN, in architecture, a round pillar, made to fupport and adorn a building, and compofed of a bafe, a fhaft, and a capital. See ARCHITECTURE.

COLUMN, in the military art, a long deep file of troops or baggage.

The firft and fecond lines of the army as they are encamped, make generally two columns on a march, filing off either from the right or left: fometimes the army marches in four, fix, or eight columns, according as the ground will allow; and each column is led by a general officer.

COLUMNEA, in botany, a genus of the didynamia angiofpermia clafs. The calix is divided into five fegments; the upper labium of the corolla is vaulted and entire, and gibbous at the bafe; the antheræ are connected; and the capfule is bilocular. There is but one fpecies, *viz.* the fcandens, a native of Martinico.

COLURES, in aftronomy and geography, two great circles fuppofed to interfect each other at right angles in the poles of the world, and to pafs through the folftitial and equinoctial points of the ecliptic. See GEOGRAPHY, and ASTRONOMY.

COLURI, a little ifland in the gulph of Engia, in the Archipelago, about feven miles fouth of Athens: of this ifland Ajax was fovereign: E. long. 24°, N. lat. 38°.

COLUTEA, BASTARD-SENA, in botany, a genus of the diadelphia decandria clafs. The pod is inflated, and opens at the top; and the calix is bilabiated. The fpecies are three, none of them natives of Britain.

COLYMBUS, the DIVER, in ornithology, a genus belonging to the order of anferes. The bill has no teeth, is fubulated, ftrait, and fharp-pointed; the teeth are in the faux or throat; the noftrils are linear, and at the bafe of the bill; and the legs are unfit for walking. There are eleven fpecies, *viz.* 1. The grylle, with palmated and three-toed feet, a red body, and the covering feathers of the wings white. It flies very low, and is a native of Greenland. 2. The troile, with palmated three-toed feet, a black body, a white breaft and belly, and the fecondary prime feathers of the wings white at the points. It is found within the arctic circle. 3. The feptentrionalis, with palmated four-toed feet, and an iron-coloured fpot under the neck. It is a native of the northern lakes of Europe. They build their nefts upon the fhore without art, and lay a couple eggs: they run with great quicknefs upon the water; and prefage ftorms by flying and crying with a miferable tone of voice. 4. The arcticus, with palmated four-toed feet, a hoary head, and a violet neck. It frequents the northern feas and lakes. 5. The glacialis, with palmated four-toed feet, and a violet head and neck. It inhabits the northern feas. 6. The immer, with palmated four-toed feet, the upper part of the body black and undulated with white, and a white belly. It inhabits the frozen feas. 7. The cryftallus, with lobated feet, a red head, a black collar, and white fecondary prime wing-feathers. It is a native of Europe. 8. The auritus, with lobated feet, a black head, and the ears are crefted and of an iron colour. It frequents the lakes of Europe and America. 9. The urinator, with lobated feet, a fmooth head, and white fpots on the wings. It is a native of the fouthern parts of Europe. 10. The dominicus, with lobated feet, a fmooth head, and the belly very much fpotted. 11. The padiceps, with lobated feet and a yellowifh body. It is a native of North America.

COLYTEA, in botany. See CERCIS.

COMA, or COMA-VIGIL, a preternatural propenfity to fleep, when neverthelefs the patient does not fleep, or, if he does, awakes immediately without any relief. See MEDICINE.

COMA SOMNOLENTUM, is when the patient continues in a profound fleep, and, when awaked, immediately relapfes, without being able to keep open his eyes. See MEDICINE.

COMARUM, in botany, a genus of plants of the icofandria polygynia clafs. The calix is divided into ten fectments; the petals are five, and lefs than the calix, and

and the feeds are ovated, fpongy, and perfiftent. There is but one fpecies, *viz.* the paluftre, a native of Europe.

COMB, an inftrument to clean, untangle, and drefs flax, wool, hair, *&c.*

Combs for wool are prohibited to be imported into Britain.

COMB is alfo the creft or red flefhy tuft growing upon a cock's head.

Lady's COMB, in botany. See SCANDIX.

COMB-FISH, in the hiftory of fhell-fifh. See OSTREA.

COMBAT, in a general fenfe, denotes an engagement, or a difference decided by arms. See BATTLE.

COMBAT, in our ancient law, was a formal trial of fome doubtful caufe or quarrel by the fwords or baftons of two champions. This form of proceeding was very frequent not only in criminal but in civil caufes; being built on a prefumption, that God would never grant the victory but to him who had the beft right. The laft trial of this kind in England, was between Donald lord Ray, appellant, and David Ramfay, efq; defendant; when, after many formalities, the matter was referred to the king's pleafure.

COMBATANT, in heraldry, a term for two beafts, as lions, *&c.* borne in a coat of arms in a fighting pofture, with their faces to each other.

COMBINATION, properly denotes an affemblage of feveral things two by two.

COMBINATION, in mathematics, is the variation or alteration of any number of quantities, letters, or the like, in all the different manners poffible.

COMEDY. See EPIC and DRAMATIC COMPOSITIONS.

COMET, an opake, fpherical, and folid body like a planet, performing revolutions about the fun in elliptical orbits, which have the fun in one of the foci. See ASTRONOMY, p. 444.

COMETARIUM, a curious machine exhibiting an idea of the revolution of a comet about the fun. See Plate XLVIII. fig. 2.

COMFREY, in botany. See SYMPHYTUM.

COMITIA, in Roman antiquity, an affembly of the people, either in the comitium or campus martius, for the election of magiftrates, or confulting on the important affairs of the republic.

There were certain days fixed for thefe affemblies, called *dies comitiales*, marked with a C in Julius Cæfar's calendar,

There were three kinds of comitia, *viz.* curiata, centuriata, and tributa, fo diftinguifhed from the manner wherein the people voted, and gave their fuffrages, *viz.* by curiæ, or parifhes, tribes, or centuries. The comitia curiata, owe their original to the divifion which Romulus made of the people into thirty curiæ, which anfwer in moft refpects to our parifhes. The comitia centuriata were inftituted by Servius Tullius. Comitial affemblies held for the election of confuls, were called confular comitia. In like manner the other comitia were named from the officer to be created, whether a tribune, pontif, ædile, or the like. The power of calling thefe affemblies, belonged at firft only to the kings: but on the eftablifhment of the democracy, the fame privilege was allowed to moft of the chief magiftrates, and fometimes to the pontiff.

COMITIALIS MORBUS, an appellation given to the epilepfy, by reafon the comitia of ancient Rome were diffolved, if any perfon in the affembly happened to be taken with this diftemper.

COMITIUM, in Roman antiquity, a large hall in the forum, where the comitia were ordinarily held.

COMMA, among grammarians, a point or character marked thus (,) ferving to denote a fhort ftop, and to divide the members of a period.

COMMA, in mufic, an interval equal to the difference of the tone major or minor, and expreffed by the ratio 81 : 80.

COMMELINA, in botany, a genus of the triandria monogynia clafs. The corolla is divided into fix fegments; it has three crofs-like nectaria inferted by their proper filaments. The fpecies are ten, none of them natives of Britain.

COMMEMORATION, in a general fenfe, the remembrance of any perfon or thing; or the doing any thing in honour of a perfon's memory, or in remembrance of any paft event. Thus the euchariſt is a commemoration of the fufferings of Jefus Chrift.

COMMENDAM, in the ecclefiaftical law, the truft or adminiftration of the revenues of a benefice, given either to a layman, to hold, by way of *depofitum*, for fix months, in order to repairs, *&c.* or to an ecclefiaftic, or beneficed perfon, to perform the paftoral duties thereof, till once the benefice is provided with a regular incumbent.

COMMENSURABLE, among geometricians, an appellation given to fuch quantities as are meafured by one and the fame common meafure.

COMMENSURABLE NUMBERS, whether integers or fractions, are fuch as can be meafured or divided by fome other number, without any remainder: fuch are 12 and 18, as being meafured by 6 or 3.

COMMENSURABLE in POWER, is faid of right lines, when their fquares are meafured by one and the fame fpace or fuperficies.

COMMENSURABLE SURDS, thofe that being reduced to their leaft terms, become true figurative quantities of their kind; and are therefore as a rational quantity to a rational one.

COMMENTARY, or COMMENT, in matters of literature, an illuftration of the difficult or obfcure paffages of an author.

COMMENTARY, or COMMENTARIES, likewife denotes a kind of hiftory, or memoirs of certain tranfactions, wherein the author had a confiderable hand: fuch are the commentaries of Cæfar.

COMMERCE.

C O M M E R C E.

COMMERCE is an operation, by which the wealth, or work, either of individuals, or of ſocieties, may be exchanged, by a ſet of men called merchants, for an equivalent, proper for ſupplying every want, without any interruption to induſtry, or any check upon conſumption.

We ſhall begin by tracing commerce to its ſource, in order to reduce it to its firſt principles.

The moſt ſimple of all trade, is that which is carried on by bartering the neceſſary articles of ſubſiſtence. If we ſuppoſe the earth free to the firſt poſſeſſor, this perſon who cultivates it will firſt draw from it his food, and the ſurplus will be the object of barter: he will give this in exchange to any one who will ſupply his other wants. This naturally ſuppoſes both a ſurplus quantity of food produced by labour, and alſo free hands; for he who makes a trade of agriculture cannot ſupply himſelf with all other neceſſaries, as well as food; and he who makes a trade of ſupplying the farmers with ſuch neceſſaries, in exchange for his ſurplus of food, cannot be employed in producing that food. The more the neceſſities of man increaſe, the more free hands are required to ſupply them; and the more free hands are required, the more ſurplus food muſt be produced by additional labour, to ſupply their demand.

This is the leaſt complex kind of trade, and may be carried on to a greater or leſs extent, in different countries, according to the different degrees of the wants to be ſupplied. In a country where there is no money, nor any thing equivalent to it, the wants of mankind will be confined to few objects; to wit, the removing the inconveniencies of hunger, thirſt, cold, heat, danger, and the like. A free man, who, by his induſtry, can procure all the comforts of a ſimple life, will enjoy his reſt, and work no more: and, in general, all increaſe of work will ceaſe, ſo ſoon as the demand for the purpoſes mentioned comes to be ſatisfied. There is a plain reaſon for this. When the free hands have procured, by their labour, wherewithal to ſupply their wants, their ambition is ſatisfied: ſo ſoon as the huſbandmen have produced the neceſſary ſurplus for relieving theirs, they work no more. Here then is a natural ſtop put to induſtry, conſequently to bartering.

The next thing to be examined is, how bartering grows into trade, properly ſo called and underſtood, according to the definition given of it above; how trade comes to be extended among men; how manufactures, more ornamental than uſeful, come to be eſtabliſhed; and how men come to ſubmit to labour, in order to acquire what is not abſolutely neceſſary for them.

This, in a free ſociety, is chiefly owing to the introduction of money, and a taſte for ſuperfluities in thoſe who poſſeſs it.

In ancient times, money was not wanting; but the taſte for ſuperfluities not being in proportion to it, the ſpecie was locked up. This was the caſe in Europe four hundred years ago. A new taſte for ſuperfluity has drawn, perhaps, more money into circulation, from our own treaſures, than from the mines of the new world. The poor opinion we entertain of the riches of our forefathers, is founded upon the modern way of eſtimating wealth, by the quantity of coin in circulation, from which we conclude, that the greateſt part of the ſpecie now in our hands muſt have come from America.

It is more, therefore, through the taſte of ſuperfluity, than in conſequence of the quantity of coin, that trade comes to be eſtabliſhed; and it is only in conſequence of trade that we ſee induſtry carry things in our days to ſo high a pitch of refinement and delicacy. Let us illuſtrate this, by comparing together the different operations of barter, ſale, and commerce.

When reciprocal wants are ſupplied by barter, there is not the ſmalleſt occaſion for money: this is the moſt ſimple of all combinations.

When wants are multiplied, bartering becomes more difficult; upon this money is introduced. This is the common price of all things: it is a proper equivalent in the hands of thoſe who want, perfectly calculated to ſupply the occaſions of thoſe who, by induſtry, can relieve them. This operation of buying and ſelling is a little more complex than the former; but ſtill we have here no idea of trade, becauſe we have not introduced the merchant, by whoſe induſtry it is carried on.

Let this third perſon be brought into play, and the whole operation becomes clear. What before we called wants, is here repreſented by the conſumer; what we called induſtry, by the manufacturer; what we called money, by the merchant. The merchant here repreſents the money, by ſubſtituting credit in its place; and as the money was invented to facilitate barter, ſo the merchant, with his credit, is a new refinement upon the uſe of money. This renders it ſtill more effectual in performing the operations of buying and ſelling. This operation is trade: it relieves both parties of the whole trouble of tranſportation, and adjuſting wants to wants, or wants to money; the merchant repreſents by turns both the conſumer, the manufacturer, and the money. To the conſumer he appears as the whole body of manufacturers; to the manufacturers as the whole body of conſumers; and to the one and the other claſs his credit ſupplies the uſe of money. This is ſufficient at preſent for an illuſtration. We now return to the ſimple operations of money in the hands of the two contracting parties, the buyer and the ſeller, in order to ſhow how men come to ſubmit to labour in order to acquire ſuperfluities.

So ſoon as money is introduced into a country, it becomes an univerſal object of want to all the inhabitants.

The conſequence is, that the free hands of the ſtate, who

who before ſtopt working, becauſe all their wants were provided for, having this new object of ambition before their eyes, endeavour, by refinements upon their labour, to remove the ſmaller inconveniences which reſult from a ſimplicity of manners. People, who formerly knew but one ſort of clothing for all ſeaſons, willingly part with a little money to procure for themſelves different ſorts of apparel properly adapted to ſummer and winter, which the ingenuity of manufacturers, and their deſire of getting money, may have ſuggeſted to their invention.

Indeed theſe refinements ſeem more generally owing to the induſtry and invention of the manufacturers, (who by their ingenuity daily contrive means of ſoftening or relieving inconveniencies, which mankind ſeldom perceive to be ſuch, till the way of removing them is contrived), than to the taſte of luxury in the rich, who, to indulge their eaſe, engage the poor to become induſtrious.

Let any man make an experiment of this nature upon himſelf, by entering into the firſt ſhop. He will no where ſo quickly diſcover his wants as there. Every thing he ſees appears either neceſſary, or at leaſt highly convenient; and he begins to wonder how he could have been ſo long without that which the ingenuity of the workman alone had invented, in order that from the novelty it might excite his deſire; for perhaps when it is bought, he will never once think of it more, nor ever apply it to the uſe for which it at firſt appeared ſo neceſſary.

Here then is a reaſon why mankind labour though not in want. They become deſirous of poſſeſſing the very inſtruments of luxury, which their avarice or ambition prompted them to invent for the uſe of others.

What has been ſaid repreſents trade in its infancy, or rather the materials with which that great fabrick is built.

We have formed an idea of the wants of mankind multiplied even to luxury, and abundantly ſupplied by the employment of all the free hands ſet apart for that purpoſe. But if we ſuppoſe the workman himſelf diſpoſing of his work, and purchaſing with it food from the farmer, cloaths from the clothier; and, in general, ſeeking for the ſupply of every want from the hands of the perſon directly employed for the purpoſe of relieving it; this will not convey an idea of trade, according to our definition.

Trade and commerce are an abbreviation of this long proceſs; a ſcheme invented and ſet on foot by merchants, from a principle of gain, ſupported and extended among men, from a principle of general utility to every individual, rich or poor, to every ſociety, great or ſmall.

Inſtead of a pin-maker exchanging his pins with fifty different perſons, for whoſe labour he has occaſion, he ſells all to the merchant for money or for credit; and, as occaſion offers, he purchaſes all his wants, either directly from thoſe who ſupply them, or from other merchants who deal with manufacturers in the ſame way his merchant dealt with him.

Another advantage of trade is, that induſtrious people in one part of the country, may ſupply cuſtomers in another, though diſtant. They may eſtabliſh themſelves in the moſt commodious places for their reſpective buſineſs, and help one another reciprocally, without making the diſtant parts of the country ſuffer for want of their labour. They are likewiſe expoſed to no avocation from their work, by ſeeking for cuſtomers.

Trade produces many excellent advantages; it marks out to the manufacturers when their branch is under or over ſtocked with hands. If it is underſtocked, they will find more demand than they can anſwer: if it is overſtocked, the ſale will be ſlow.

Intelligent men, in every profeſſion, will eaſily diſcover when theſe appearances are accidental, and when they proceed from the real principles of trade.

Poſts, and correſpondence by letters, are a conſequence of trade; by the means of which merchants are regularly informed of every augmentation or diminution of induſtry in every branch, in every part of the country. From this knowldge they regulate the prices they offer; and as they are many, they ſerve as a check upon one another, from the principles of competition.

From the current prices the manufacturers are as well informed as if they kept the correſpondence themſelves: the ſtateſman feels perfectly where hands are wanting, and young people deſtined to induſtry, obey, in a manner, the call of the public, and fall naturally in to ſupply the demand.

Two great aſſiſtances to merchants, eſpecially in the infancy of trade, are public markets for collecting the work of ſmall dealers, and large undertakings in the manufacturing way by private hands. By theſe means the merchants come at the knowledge of the quantity of work in the market, as on the other hand the manufacturers learn, by the ſale of the goods, the extent of the demand for them. Theſe two things being juſtly known, the price of goods is eaſily fixed.

Public ſales ſerve to correct the ſmall inconveniencies which proceed from the operations of trade. A ſet of manufacturers got all together into one town, and entirely taken up with their induſtry, are thereby as well informed of the rate of the market as if every one of them carried thither his work, and upon the arrival of the merchant, who readily takes it off their hands, he has not the leaſt advantage over them from his knowledge of the ſtate of demand. This man both buys and ſells in what is called wholeſale; and from him retailers purchaſe, who diſtribute the goods to every conſumer throughout the country. Theſe laſt buy from wholeſale merchants in every branch, that proportion of every kind of merchandize which is ſuitable to the demand of their borough, city, or province.

Thus all inconveniencies are prevented, at ſome additional coſt to the conſumer, who muſt naturally reimburſe the whole expence. The diſtance of the manufacturer, the obſcurity of his dwelling, the caprice in ſelling his work, are quite removed; the retailer has all in his ſhop, and the public buys at a current price.

How the Prices of Goods are determined by Trade.

In the price of goods, two things muſt be conſidered as really exiſting, and quite different from one another; to

to wit, the real value of the commodity, and the profit upon alienation.

I. The firſt thing to be known of any manufacture, when it comes to be ſold, is, how much of it a perſon can perform in a day, a week, a month, according to the nature of the work, which may require more or leſs time to bring it to perfection. In making ſuch eſtimates, regard is to be had only to what, upon an average, a workman of the country in general may perform, without ſuppoſing him the beſt or the worſt in his profeſſion, or having any peculiar advantage or diſadvantage as to the place where he works.

Hence the reaſon why ſome people thrive by their induſtry, and others not; why ſome manufactures flouriſh in one place, and not in another.

II. The ſecond thing to be known, is the value of the workman's ſubſiſtence, and neceſſary expence, both for ſupplying his perſonal wants, and providing the inſtruments belonging to his profeſſion, which muſt be taken upon an average as above; except when the nature of the work requires the preſence of the workman in the place of conſumption: for although ſome trades, and almoſt every manufacture, may be carried on in places at a diſtance, and therefore may fall under one general regulation as to prices; yet others there are which, by their nature, require the preſence of the workman in the place of conſumption; and in that caſe the prices muſt be regulated by circumſtances relative to every particular place.

III. The third and laſt thing to be known, is the value of the materials, that is, the firſt matter employed by the workman; and if the object of his induſtry be the manufacture of another, the ſame proceſs of inquiry muſt be gone through with regard to the firſt, as with regard to the ſecond: and thus the moſt complex manufactures may be at laſt reduced to the greateſt ſimplicity.

Theſe three articles being known, the price of manufacture is determined. It cannot be lower than the amount of all the three, that is, than the real value; whatever it is higher, is the manufacturer's profit. This will ever be in proportion to demand, and therefore will fluctuate according to circumſtances.

Hence appears the neceſſity of a great demand, in order to promote flouriſhing manufactures.

By the extenſive dealings of merchants, and their conſtant application to the ſtudy of the balance of work and demand, all the above circumſtances are known to them, and are made known to the induſtrious, who regulate their living and expence according to their certain profit.

Employ a workman in a country where there is little trade or induſtry, he proportions his price always to the urgency of your want, or your capacity to pay; but ſeldom to his own labour. Employ another in a country of trade, he will not impoſe upon you, unleſs perhaps you be a ſtranger, which ſuppoſes your being ignorant of the value; but employ the ſame workman in a work not uſual in the country, conſequently not demanded, conſequently not regulated as to the value, he will proportion his price as in the firſt ſuppoſition.

We may therefore conclude from what has been ſaid, that in a country where trade has been eſtabliſhed, manufactures muſt flouriſh, from the ready ſale, the regulated price of work, and the certain profit reſulting from induſtry. Let us next inquire into the conſequences of ſuch a ſituation.

How foreign Trade opens to an induſtrious People, and the Conſequences of it to the Merchants who ſet it on foot.

The firſt conſequence of the ſituation deſcribed in the preceding ſection is, that wants are eaſily ſupplied, for the adequate value of the thing wanted.

The next conſequence is, the opening of foreign trade under its two denominations of paſſive and active. Strangers and people of diſtant countries, finding the difficulty of having their wants ſupplied at home, and the eaſe of having them ſupplied from this country, immediately have recourſe to it. This is paſſive trade. The active is when merchants, who have executed this plan at home with ſucceſs, begin to tranſport the labour of their countrymen into other regions, which either produce, or are capable of producing ſuch articles of conſumption, proper to be manufactured, as are moſt demanded at home; and conſequently will meet with the readieſt ſale, and fetch the largeſt profits.

Here then is the opening of foreign trade, under its two denominations of active and paſſive.

What then are the conſequences of this new commerce to our merchants, who have left their homes in queſt of gain aboard?

The firſt is, that, arriving in any new country, they find themſelves in the ſame ſituation, with regard to the inhabitants, as the workman in the country of no trade, with regard to thoſe who employed him; that is, they proportion the price of their goods to the eagerneſs of acquiring, or the capacity of paying, in the inhabitants, but never to their real value.

The firſt profits then, upon this trade, muſt be very conſiderable; and the demand from ſuch a country will be *high* or *low*, *great* or *ſmall*, according to the ſpirit, not the real wants of the people: for theſe in all countries muſt firſt be ſupplied by the inhabitants themſelves, before they ceaſe to labour.

If the people of this not-trading country be abundantly furniſhed with commodities uſeful to the traders, they will eaſily part with them, at firſt, for the inſtruments of luxury and eaſe; but the great profit of the traders will inſenſibly increaſe the demand for the productions of their new correſpondents; this will have the effect of producing a competition between themſelves, and thereby of throwing the demand on their ſide. This is perpetually a diſadvantage in traffic: the moſt unpoliſhed nations in the world quickly perceive the effects of it; and are taught to profit by the diſcovery, in ſpite of the addreſs of thoſe who are the moſt expert in commerce.

The traders will therefore be very fond of falling upon every method and contrivance to inſpire this people with a taſte of refinement and delicacy. Abundance of fine preſents, conſiſting of every inſtrument of luxury and ſuperfluity, the beſt adapted to the genius of the people, will be given to the prince and leading men among them. Workmen will even be employed at home to ſtudy the taſte

taste of the strangers, and to captivate their desires by every possible means. The more eager they are of presents, the more lavish the traders will be in bestowing and diversifying them. It is an animal put up to fatten, the more he eats the sooner he is fit for slaughter. When their taste for superfluity is fully formed, when the relish for their former simplicity is sophisticated, poisoned, and obliterated, then they are surely in the fetters of the traders, and the deeper they go, the less possibility there is of their getting out. The presents then will die away, having served their purpose; and if afterwards they are found to be continued, it will probably be to support the competition against other nations, who will incline to share of the profits.

If, on the contrary, this not-trading nation does not abound with commodities useful to the traders, these will make little account of trading with them, whatever their turn may be; but, if we suppose this country inhabited by a laborious people, who, having taken a taste for refinement from the traders, apply themselves to agriculture, in order to produce articles of subsistence, they will solicit the merchants to give them part of their manufactures in exchange for those; and this trade will undoubtedly have the effect of multiplying numbers in the trading nation. But if food cannot be furnished, nor any other branch of production found out to support the correspondence, the taste for refinement will soon die away, and trade will stop in this quarter.

Had it not been for the furs in those countries adjacent to Hudson's Bay, and in Canada, the Europeans never would have thought of supplying instruments of luxury to those nations; and if the inhabitants of those regions had not taken a taste for the instruments of luxury, furnished to them by the Europeans, they never would have become so indefatigable nor so dextrous hunters. At the same time we are not to suppose, that ever these Americans would have come to Europe in quest of our manufactures. It is therefore owing to our merchants, that these nations are become in any degree fond of refinement; and this taste, in all probability, will not soon exceed the proportion of the productions of their country. From these beginnings of foreign trade it is easy to trace its increase.

One step towards this, is the establishing correspondences in foreign countries; and these are more or less necessary in proportion as the country where they are established is more or less polished or acquainted with trade. They supply the want of posts, and point out to the merchants what proportion the productions of the country bear to the demand of the inhabitants for manufactures. This communicates an idea of commerce to the not-trading nation, and they insensibly begin to fix a determined value upon their own productions, which perhaps bore no determined value at all before.

Let us trace a little the progress of this refinement in the savages, in order to shew how it has the effect of throwing the demand upon the traders, and of creating a competition among them, for the productions of the new country.

Experience shews, that, in a new discovered country, merchants constantly find some article or other of its productions, which turns out to a great account in commerce; and we see that the longer such a trade subsists, and the more the inhabitants take a taste far European manufactures, the more their own productions rise in their value, and the less profit is made by trading with them, even in cases where the trade is carried on by companies; which is a very wise institution for one reason, that it cuts off a competition between our merchants.

This is the best means of keeping prices low in favour of the nation; however it may work a contrary effect with respect to individuals who must buy from these monopolies.

When companies are not established, and when trade is open, our merchants, by their eagerness to profit by the new trade, betray the secrets of it, they enter into competition for the purchase of the foreign produce, and this raises prices, and favours the commerce of the most ignorant savages.

Consequences of the Introduction of a passive foreign Trade among a People who live in Simplicity and Idleness.

We now suppose the arrival of traders, all in one interest, with instruments of luxury and refinement, at a port in a country of great simplicity of manners, abundantly provided by nature with great advantages for commerce, and peopled by a nation capable of adopting a taste for superfluities.

The first thing the merchants do is, to expose their goods, and point out the advantages of many things, either agreeable or useful to mankind in general, such as wines, spirits, instruments of agriculture, arms, and ammunition for hunting, nets for fishing, manufactures for clothing, and the like. The advantages of these are presently perceived, and such commodities are eagerly sought after.

The natives on their side produce what they most esteem, generally something superfluous or ornamental. The traders, after examining all circumstances, determine the object of their demand, giving the least quantity possible in return for this superfluity, in order to impress the inhabitants with a high notion of the value of their own commodities; but as this parsimony may do more hurt than good to their interest, they are very generous in making presents, from the principles mentioned above.

When the exchange is completed, and the traders depart, regret is commonly mutual; the one and the other are sorry that the superfluities of the country fall short. A return is promised by the traders, and assurances are given by the natives of a better provision another time.

What are the first consequences of this revolution?

It is evident, that, in order to supply an equivalent for this new want, more hands must be set to work than formerly. And it is evident also, that this augmentation of industry will not essentially increase numbers: Why? Because the produce of the industry is, in this case, intended to be exported. But, if we can find out any additional consumption at home, even implied by this

this new trade, it will have the effect of augmenting numbers. An example will make this plain.

Let us fuppofe the fuperfluity of this country to be the fkins of wild beafts, not proper for food; the manufacture fought for, brandy. The brandy is fold for furs. He who has furs, or he who can fpare time to hunt for them, will drink brandy in proportion: but there is no reafon to conclude from this fimple operation, that one man more in the country muft neceffarily be fed, or that any augmentation of agriculture muft of confequence enfue from this new traffic.

But let us throw in a circumftance which may apply an additional confumption at home, and then examine the confequences.

A poor creature who has no equivalent to offer for food, who is miferable, and ready to perifh for want of fubfiftence, goes a hunting, and kills a wolf; he comes to a farmer with the fkin, and fays. You are well fed, but you have no brandy; if you will give me a loaf, I will give you this fkin, which the ftrangers are fo fond of, and they will give you brandy. But, fays the farmer, I have no more bread than what is fufficient for my own family. As for that, replies the other, I will come and dig in your ground, and you and I will fettle our account as to the fmall quantity I defire of you. The bargain is made; the poor fellow gets his loaf, and lives at leaft; perhaps he marries, and the farmer gets a dram. But had it not been for this dram, that is, this new want, which was purchafed by the induftry of this poor fellow, by what argument could he have induced the farmer to part with a loaf?

Here the fentiment of chartiy is excluded. This alone is a principle of multiplication; but as true it is, on the other hand, that conld the poor fellow have got bread by begging, he would not probably have gone a-hunting.

Here then it appears, that the very dawning of trade, in the moft unpolifhed countries, implies a multiplication. This is enough to point out the firft ftep, and to connect the fubject of our prefent inquiries with what has been already difcuffed in relation to other circumftances.

So foon as all the furs are difpofed of, and a tafte for fuperfluity is introduced, both the traders and the natives will be equally interefted in the advancement of induftry in this country. Many new objects of profit for the firft will be difcovered, which the proper employment of the inhabitants, in reaping the natural advantages of their foil and climate, will make effectual. The traders will therefore endeavour to fet on foot many branches of induftry among the favages, and the allurements of brandy, arms, and clothing, will animate thefe in the purfuit of them.

When once this revolution is brought about; when thofe who formerly lived in fimplicity become induftrious; manners put one a new face.

That is to fay, we now find two trading nations inftead of one, with this difference, however, that as hitherto we have fuppofed the merchants all in one intereft, the compound demand, that is, the competition of the buyers, has been, and muft ftill continue on the fide of the natives. This is a great prejudice to their intereft; but as it is not fuppofed fufficient to check their induftry, nor to reftrain their confumption of the manufactures, let us here examine a little more particularly the confequences of the principle of demand in fuch a fituation; for although we allow, that it can never change fides, yet it may admit of different modifications, and produce different effects, as we fhall prefently perceive.

The merchants we fuppofe all in one intereft, confequently there can be no competition among them; confequently no check can be put upon their raifing their prices, as long as the prices they demand are complied with. So foon as they are raifed to the full extent of the abilities of the natives, or of their inclination to buy, the merchants have the choice of three things, which are all perfectly in their option; and the preference to be given to the one or the other, depends entirely upon themfelves, and upon the circumftances we are going to point out.

Firft, they may fupport they *high* demand; that is, not lower their price; which will preferve a high eftimation of the manufactures in the opinion of the inhabitants, and render the profits upon their trade the greateft poffible. This part they may poffibly take, if they perceive the natives doubling their diligence, in order to become able, in time, to purchafe confiderable cargoes at a high value; from which fuppofition is implied a ftrong difpofition in the people to become luxurious, fince nothing but want of ability prevents them from complying with the higheft demand: but ftill another circumftance muft concur, to engage the merchants not to lower their price. The great proportion of the goods they feek for in return, muft be found in the hands of a few. This will be the cafe if flavery be eftablifhed: for then there muft be many poor and few rich: and they are commonly the rich confumers who proportion the price they offer, rather to their defires, than to the value of the thing.

The fecond thing which may be done is, to open the door to a *great* demand; that is, to lower their prices. This will fink the value of the manufactures in the opinion of the inhabitants, and render profits lefs in proportion, although indeed, upon the voyage, the profits may be greater.

This part they will take, if they perceive the inhabitants do not incline to confume great quantities of the merchandize at a high value, either for want of abilities or inclination; and alfo, if the profits upon the trade depend upon a large confumption, as is the cafe in merchandize of a low value, and fuited chiefly to the occafions of the lower fort. Such motives of expediency will be fufficient to make them neglect a *high* demand, and prefer a *great* one; and the more, when there is a likelihood that the confumption of low-priced goods in the beginning may beget a tafte for others of a higher value, and thus extend in general the tafte of fuperfluity.

A third part to be taken, is the leaft politic, and perhaps the moft familiar. It is to profit by the competition between the buyers, and encourage the rifing of demand as long as poffible; when this comes to a ftop, to make a kind of auction, by firft bringing down the prices

to

to the level of the higheſt bidders, and ſo to deſcend by degrees, in proportion as demand ſinks. Thus we may ſay with propriety, that demand commonly becomes *great*, in proportion as prices ſink. By this operation, the traders will profit as much as poſſible, and ſell off as much of their goods as the profits will permit.

But this plan, in a new diſcovered country, is not politic, as it both diſcovers a covetouſneſs and a want of faith in the merchants, and alſo throws open the ſecrets of their trade to thoſe who ought to be kept ignorant of them.

Let us next ſuppoſe, that the large profits of our merchants ſhall be diſcovered by others, who arrive at the ſame ports in a ſeparate intereſt, and who enter into no combination which might prevent the natural effects of competition.

Let the ſtate of demand among the natives be ſuppoſed the ſame as formerly, both as to *height* and *greatneſs*, in conſequence of the operation of the different principles, which might have induced our merchants to follow one or other of the plans we have been deſcribing; we muſt however ſtill ſuppoſe, that they have been careful to preſerve conſiderable profits upon every branch.

If we ſuppoſe the inhabitants to have increaſed in numbers, wealth, and taſte for ſuperfluity, ſince the laſt voyage, demand will be found rather on the riſing hand. Upon the arrival of the merchants in competition with the former, both will offer to ſale: but if both ſtand to the ſame prices, it is very natural to ſuppoſe, that the former dealers will obtain a preference; as, *cæteris paribus*, it is always an advantage to know and to be known. The laſt comers, therefore, have no other way left to counter-balance this advantage, but to lower their prices.

This is a new phenomenon: here the fall of prices is not voluntary as formerly; nor conſented to from expediency; not owing to a failure of demand, but to the influence of a new principle of commerce, to wit, a double competition, which we ſhall now examine.

Of Double Competition.

When *competition* is much ſtronger on one ſide of the contract than on the other, it is called *ſimple*. This is the ſpecies of competition which is implied in the term *high demand*, or when it is ſaid that *demand raiſes prices*.

Double competition is, when, in a certain degree, it takes place on both ſides of the contract at once, or vibrates alternately from one to the other. This is what reſtrains prices to the adequate value of merchandize.

The great difficulty is to diſtinguiſh clearly between the principles of *demand*, and thoſe of *competition*: here then follows the principal differences between the two, relatively to the effects they produce ſeverally in the mercantile contract of buying and ſelling, which we here expreſs ſhortly by the word *contract*.

Simple demand is what brings the quantity of a commodity to market. Many demand, who do not buy; many offer, who do not ſell. This demand is called *great* or *ſmall*; it is ſaid to *increaſe*, to *augment*, to *ſwell*; and is expreſſed by theſe and other ſynonimous terms, which mark an augmentation or diminution of quantity. In this ſpecies, two people never demand the ſame thing, but a part of the ſame thing, or things quite alike.

Compound demand is the principle which raiſes prices, and never can make them ſink; becauſe in this caſe more than one demands the very ſame thing. It is ſolely applicable to the buyers, in relation to the price they offer. This demand is called ***high*** or ***low***, and is ſaid to *riſe*, to *fall*, to *mount*, to *ſink*, and is expreſſed by theſe and other ſynonimous terms.

Simple competition, when between buyers, is the ſame as *compound* or *high demand*; but differs from it in ſo far, as this may equally take place among ſellers, which *compound demand* cannot; and then it works a contrary effect: it makes prices *ſink*, and is ſynonimous with *low demand*: it is this competition which overturns the balance of work and demand.

Double competition is what is underſtood to take place in almoſt every operation of trade; it is this which prevents their exceſſive riſe of prices; it is this which prevents their exceſſive fall. While *double competition* prevails, the balance is perfect, trade and induſtry flouriſh.

The capital diſtinction, therefore, between the terms *demand* and *competition* is, that *demand* is conſtantly relative to the buyers; and when money is not the price, as in barter, then it is relative to that ſide upon which the greateſt *competition* is found.

We therefore ſay, with regard to *prices*, demand is *high* or *low*. With regard *to the quantity of merchandize*, demand is *great* or *ſmall*. With regard *to competition*, it is always called *great* or *ſmall*, *ſtrong* or *weak*.

Competition is, with equal propriety, applicable to both parties in the contract. A *competition* among buyers is a proper expreſſion; a *competition* among ſellers, who have the merchandize, is fully as eaſily underſtood, tho' it be not quite ſo ſtriking, for reaſons which an example will make plain.

You come to a fair, where you find a great variety of every kind of merchandize, in the poſſeſſion of different merchants. Theſe, by offering their goods to ſale, conſtitute a tacit competition; every one of them wiſhes to ſell in preference to another, and at the ſame time with the beſt advantage to himſelf.

The buyers begin, by cheapning at every ſhop. The firſt price aſked marks the covetouſneſs of the ſeller; the firſt price offered, the avarice of the buyer. From this operation competition begins to work its effects on both ſides, and ſo becomes double. The principles which influence this operation are now to be deduced.

It is impoſſible to ſuppoſe the ſame degree of eagerneſs, either to buy or to ſell, among ſeveral merchants; becauſe the degree of eagerneſs is exactly in proportion to their view of profit; and as theſe muſt neceſſarily be influenced and regulated by different circumſtances, that buyer, who has the beſt proſpect of ſelling again with profit, obliges him, whoſe proſpect is not ſo good, to content himſelf with leſs; and that ſeller, who has bought to the beſt advantage, obliges him, who has paid dearer

dearer for the merchandize, to moderate his desire of gain.

It is from these principles, that competition among buyers and sellers must take place. This is what confines the fluctuation of prices within limits which are compatible with the reasonable profits of both buyers and sellers; for we must constantly suppose the whole operation of buying and selling to be performed by merchants; the buyer cannot be supposed to give so high a price as that which he expects to receive, when he distributes to the consumers, nor can the seller be supposed to accept of a lower than that which he paid to the manufacturer. This competition is properly called double, because of the difficulty to determine upon which side it stands; the same merchant may have it in his favour upon certain articles, and against him upon others; it is continually in vibration, and the arrival of every post may less or more pull down the heavy scale.

In every transaction between merchants, the profit resulting from the sale must be exactly distinguished from the value of the merchandize. The first *may* vary, the last never *can*. It is this profit alone which can be influenced by competition; and it is for that reason we find such uniformity every where in the prices of goods of the same quality.

The competition between sellers does not appear so striking, as that between buyers; because he who offers to sale, appears only passive in the first operation; whereas the buyers present themselves one after another; they make a demand when the merchandize is refused to one at a certain price, a second either offers more, or does not offer all: but so soon as another seller finds his account in accepting the price the first had refused, then the first enters into competition, providing his profits will admit his lowering the first price, and thus competition takes place among the sellers, until the profits upon their trade prevent prices from falling lower.

In all markets this competition is varying, though insensibly, on many occasions; but in others, the vibrations are very perceptible. Sometimes it is found strongest on the side of the buyers; and in proportion as this grows, the competition between the sellers diminishes. When the competition between the former has raised prices to a certain standard, it comes to a stop; then the competition changes sides, and takes place among the sellers, eager to profit of the highest price. This makes prices fall, and according as they fall, the competition among the buyers diminishes. They still wait for the lowest period. At last it comes; and then perhaps some new circumstance, by giving the balance a kick, disappoints their hopes. If therefore it ever happens, that there is but one interest upon one side of the contract, as in the example in the former section, where we supposed the sellers united, you perceive, that the rise of the price, occasioned by the competition of the buyers, and even its coming to a stop, could not possibly have the effect of producing any competition on the other side; and therefore, if prices come afterwards to sink, the fall must have proceeded from the prudential considerations of adapting the price to the faculties of those who, from the height of it, had withdrawn their demand.

From these principles of competition, the forestalling of markets is made a crime, because it diminishes the competition which ought to take place between different people, who have the same merchandize to offer to sale. The forestaller buys all up, with an intention to sell with more profit, as he has by that means taken other competitors out of the way, and appears with a single interest on one side of the contract, in the face of many competitors on the other. This person is punished by the state, because he has prevented the price of the merchandice from becoming justly proportioned to the real value; he has robbed the public, and enriched himself; and in the punishment he makes restitution. Here occur two questions to be resolved, for the sake of illustration.

Can competition among buyers possibly take place, when the provision made is more than sufficient to supply the quantity demanded? On the other hand, can competition take place among the sellers, when the quantity demanded exceeds the total provision made for it?

We think it may in both cases; because in the one and the other, there is a competition implied on one side of the contract, and the very nature of this competition implies a possibility of its coming on the other, provided separate interests be found upon both sides. But to be more particular:

1. Experience shews, that however justly the proportion between the demand and the supply may be determined in fact, it is still next to impossible to discover it exactly, and therefore the buyers can only regulate the prices they offer, by what they may reasonably expect to sell for again. The sellers, on the other hand, can only regulate the prices they expect, by what the merchandize has cost them when brought to market. We have already shewn, how, under such circumstances, the several interests of individuals affect each other, and make the balance vibrate.

2. The proportion between the supply and the demand is seldom other than *relative* among merchants, who are supposed to buy and sell, not from necessity, but from a view to profit. What we mean by *relative* is, that their demand is *great* or *small*, according to prices; there may be a great demand for grain at 35 s. *per* quarter, and no demand at all for it at 40 s.; that is, among merchants.

It is essential to attend to the smallest circumstance in matters of this kind. The circumstance we mean, is the difference we find in the effect of competition, when it takes place purely among merchants on both sides of the contract, and when it happens, that either the consumers mingle themselves with the merchant buyers, or the manufacturers, that is, the furnishers, mingle themselves with the merchant-sellers. This combination we shall illustrate, by the solution of another question, and then conclude with a few reflections upon the whole.

Can there be no case formed, where the competition upon one side may subsist, without a possibility of its taking

king place on the other, although there ſhould be ſeparate intereſts upon both ?

The caſe is hardly ſuppoſable among merchants, who buy and ſell with a view to profit; but it is abſolutely ſuppoſable, and that is all, when the direct conſumers are the buyers; when the circumſtances of one of the parties is perfectly known; and when the competition is ſo ſtrong upon one ſide, as to prevent a poſſibility of its becoming double, before the whole proviſion is ſold off, or the demand ſatisfied. Let us have recourſe to examples.

Grain arriving in a ſmall quantity, at a port where the inhabitants are ſtarving, produces ſo great a competition among the conſumers, who are the buyers, that their neceſſity becomes evident; all the grain is generally bought up before prices can riſe ſo high as to come to a ſtop; becauſe nothing but want of money, that is, an impoſſibilily of complying with the prices demanded by the merchants, can reſtrain them: but if you ſuppoſe, even here, that prices come naturally to a ſtop; or that, after ſome time, they fall lower, from prudential conſiderations; then there is a poſſibility of a competition taking place among the ſellers, from the principles above deduced. If, on the contrary, the ſtop is not natural, but occaſioned by the interpoſition of the magiſtrate, from humanity, or the like, there will be no competition, becauſe then the principles of commerce are ſuſpended; the ſellers are reſtrained on one ſide, and they reſtrain the buyers on the other. Or rather, indeed, it is the magiſtrate, or compaſſion, who in a manner fixes the price, and performs the office of both buyer and ſeller.

A better example ſtill may be found, in a competition among ſellers; where it may be ſo ſtrong, as to render a commodity in a manner of no value at all, as in the caſe of an uncommon and unexpected draught of fiſh, in a place of ſmall conſumption, when no preparations have been made for ſalting them. There can be then no competition among the buyers; becauſe the market cannot laſt, and they find themſelves entirely maſters, to give what price they pleaſe, being ſure the ſellers muſt accept of it, or loſe their merchandize. In the firſt example, humanity commonly ſtops the activity of the principle of competition; in the other it is ſtopt by a certain degree of fair-dealing, which forbids the accepting of a merchandize for nothing.

In proportion therefore as the riſing of prices can ſtop demand, or the ſinking of prices can increaſe it, in the ſame proportion will competition prevent either the riſe or the fall from being carried beyond a certain length: and if ſuch a caſe can be put, where the riſing of prices cannot ſtop demand, nor the lowering of prices augment it, in ſuch caſes double competition has no effect; becauſe theſe circumſtances unite the moſt ſeparate intereſts of buyers and ſellers in the mercantile contract; and when upon one ſide there is no ſeparate intereſt, there can then be no competition.

From what has been ſaid, we may form a judgment of the various degrees of competition. A book not worth a ſhilling, a fiſh of a few pounds weight, are often ſold for conſiderable ſums. The buyers here are not merchants. When an ambaſſador leaves a court in a hurry, things are ſold for leſs than the half of their value: he is no merchant, and his ſituation is known. When, at a public market, there are found conſumers, who make their proviſion; or manufacturers, who diſpoſe of their goods for preſent ſubſiſtence; the merchants, who are reſpectively upon the oppoſite ſide of the contract to theſe, profit of their competition; and thoſe who are reſpectively upon the ſame ſide with them, ſtand by with patience, until they have finiſhed their buſineſs. Then matters come to be carried on between merchant and merchant, and then profits may riſe and fall, in the proportion of quantity to demand; that is to ſay, if the proviſion is leſs than the demand, the competition among the demanders, or the riſe of the price, will be in the compound proportion of the falling ſhort of the commodity, and of the proſpect of ſelling again with profit. It is this combination which regulates the competition, and keeps it within bounds. It can affect but the profits upon the tranſaction; the intrinſic value of the commodity ſtands immoveable: nothing is ever ſold below the real value; nothing is ever bought for more than it may probably bring. We mean in general. Whereas, ſo ſoon as conſumers and needy manufacturers mingle in the operation, all proportion is loſt. The competition between them is too ſtrong for the merchants; the balance vibrates by jerks. In ſuch markets merchants ſeldom appear: the principal objects there, are the fruits and productions of the earth, and articles of the firſt neceſſity for life, not manufactures ſtrictly ſo called. A poor fellow often ſells, to purchaſe bread to eat; not to pay what he did eat while he was employed in the work he diſpoſes of. The conſumer often meaſures the value of what he is about to purchaſe, by the weight of his purſe, and his deſire to conſume.

Of what is called Expence, Profit, and Loſs.

The term *expence*, when ſimply expreſſed, without any particular relation, is always underſtood to be relative to money. This kind is diſtinguiſhed under the three heads of *private*, *public*, and *national*.

1. *Private* expence is, what a private perſon, or private ſociety, lays out, either to provide articles of conſumption, or ſomething more permanent, which may be conducive to their eaſe, convenience, or advantage. Thus we ſay, *a large domeſtic expence*, relative to one who ſpends a great income. We ſay, a merchant has been at *great expence* for magazines, for living, for clerks, &c. but never that he has been at any in buying goods. In the ſame way a manufacturer may expend for building, machines, horſes, and carriages, but never for the matter he manufactures. When a thing is bought, in order to be ſold again, the ſum employed is called money *advanced*; when it is bought not to be ſold, it may be ſaid to be *expended*.

2. *Public expence* is, the employment of that money, which has been contributed by individuals, for the current ſervice of the ſtate. The contribution, or gathering it together, repreſents the effects of many articles of *private expence*; the laying it out when collected, is *public expence*.

3. *National*

3. *National expence*, is what is expended out of the country: this is what diminiſhes national wealth. The principal diſtinction to be here attended to, is between *public expence*, or the laying out of public money, and *national expence*, which is the alienating the nation's wealth in favour of ſtrangers. Thus the greateſt *public expence* imaginable, may be no national expence; becauſe the money may remain at home. On the other hand, the ſmalleſt *public*, or even *private expence*, may be a national expence; becauſe the money may go abroad.

Profit and *loſs* is divided into *poſitive*, *relative*, and *compound*. *Poſitive profit*, implies no loſs to any body; it reſults from an augmentation of labour, induſtry, or ingenuity, and has the effect of ſwelling or augmenting the public good.

Poſitive loſs, implies no profit to any body; it is what reſults from the ceſſation of the former, or of the effects reſulting from it, and may be ſaid to diminiſh the public good.

Relative profit, is what implies a loſs to ſome body; it marks a vibration of the balance of wealth between parties, but implies no addition to the general ſtock.

Relative loſs, is what, on the contrary, implies a profit to ſome body; it alſo marks a vibration of the balance, but takes nothing from the general ſtock.

The *compound* is eaſily underſtood; it is that ſpecies of profit and loſs which is partly *relative*, and partly *poſitive*.

The general Conſequences reſulting to a trading Nation, upon the opening of an active foreign Commerce.

A NATION which remains paſſive in her commerce, is at the mercy of thoſe who are active, and muſt be greatly favoured, indeed, by natural advantages, or by a conſtant flux of gold and ſilver from her mines, to be able to ſupport a correſpondence, not entirely hurtful to the augmentation of her wealth.

When we look upon the wide field which here opens to our view, we are perplexed with too great a variety of objects. In one part, we ſee a decent and comely beginning of induſtry; wealth flowing gently in, to recompence ingenuity; numbers both augmenting, and every one becoming daily more uſeful to another; agriculture proportionally extending itſelf; no violent revolutions; no exorbitant profits; no inſolence among the rich; no exceſſive miſery among the poor; multitudes employed in producing; great oeconomy upon conſumption; and all the inſtruments of luxury, daily produced by the hands of the diligent, going out of the country for the ſervice of ſtrangers; not remaining at home for the gratification of ſenſuality. At laſt the augmentations come inſenſibly to a ſtop. Then theſe rivers of wealth, which were in briſk circulation through the whole world, and which returned to this trading nation as blood returns to the heart, only to be thrown out again by new pulſations, begin to be obſtructed in their courſe; and flowing abroad more ſlowly than before, come to form ſtagnations at home. Theſe, impatient of reſtraint, ſoon burſt out into domeſtic circulation. Upon this cities ſwell in magnificence of buildings; the face of the country is adorned with palaces, and becomes covered with groves; luxury ſhines triumphant in every part; inequality becomes more ſtriking to the eye; and want and miſery appear more deformed, from the contraſt: even fortune grows more whimſical in her inconſtancy; the beggar of the other day, now rides in his coach; and he who was born in a bed of ſtate, is ſeen to die in a goal, or in an almshouſe. Such are the effects of great domeſtic circulation.

The ſtateſman looks about with amazement; he, who was wont to conſider himſelf as the firſt man in the ſociety in every reſpect, perceives himſelf, perhaps, eclipſed by the luſtre of private wealth, which avoids his graſp when he attempts to ſeize it. This makes his government more complex and more difficult to be carried on; he muſt now avail himſelf of art and addreſs, as well as of power and force. By the help of cajoling and intrigues, he gets a little into debt; this lays a foundation for public credit, which, growing by degrees, and in its progreſs aſſuming many new forms, becomes, from the moſt tender beginnings, a moſt formidable monſter, ſtriking terror into thoſe who cheriſhed it in its infancy. Upon this, as upon a triumphant war-horſe, the ſtateſman gets a-ſtride; he then appears formidable a-new; his head turns giddy; he is choaked with the duſt he has raiſed; and at the moment he is ready to fall, to his utter aſtoniſhment and ſurprize, he finds a ſtrong monied intereſt, of his own creating, which, inſtead of ſwallowing him up as he apprehended, flies to his ſupport. Through this he gets the better of all oppoſition, he eſtabliſhes taxes, multiplies them, mortgages his fund of ſubſiſtence; either becomes a bankrupt, and riſes again from his aſhes; or if he be leſs audacious, he ſtands trembling and tottering for a while on the brink of the political precipice. From one or the other of theſe perilous ſituations, he begins to diſcover an endleſs path, which, after a multitude of windings, ſtill returns into itſelf, and continues an equal courſe through this vaſt labyrinth.

It is now full time to leave off rhapſody, and return to reaſoning and cool inquiry, concerning the more immediate and more general effects and revolutions produced by the opening of a foreign trade in a nation of induſtry.

The firſt and moſt ſenſible alteration will be an increaſe of demand for manufacturers, becauſe by ſupplying the wants of ſtrangers, the number of conſumers will now be conſiderably augmented. What again will follow upon this, muſt depend upon circumſtances.

If this revolution in the ſtate of demand ſhould prove too violent, the conſequence of it will be to *raiſe* demand; if it ſhould prove gradual, it will *increaſe* it. This diſtinction is well underſtood, and the conſequence appears juſt: for, if the ſupply do not increaſe in proportion to the demand, a competition will enſue among the demanders; which is the common effect of ſuch ſudden revolutions. If, on the other hand, a gentle increaſe of demand ſhould be accompanied with a proportional ſupply, the whole induſtrious ſociety will grow in vigour, and in wholſome ſtature, without being ſenſible

of

of any great advantage or inconveniency; the change of their circumſtances will even be imperceptible.

The immediate effects of the violent revolution will, in this example, be flattering to ſome, and diſagreeable to others. Wealth will be found daily to augment, from the riſing of prices, in many branches of induſtry. This will encourage the induſtrious claſſes, and the idle conſumers at home will complain. We have already dwelt abundantly long upon the effects reſulting from this to the lower claſſes of the people, in providing them with a certain means of ſubſiſtence. Let us now examine in what reſpect even the higher claſſes will be made likewiſe to feel the good effects of this general change, although at firſt they may ſuffer a temporary inconveniency from it.

Farmers, as has been obſerved, will have a greater difficulty in finding ſervants, who, inſtead of labouring the ground, will chuſe to turn themſelves to manufactures. This we have conſidered in the light of purging the lands of ſuperfluous mouths; but every conſequence in this great chain of politics draws other conſequences after it, and as they follow one another, things put on different faces, which affect claſſes differently. The purging of the land is but one of the firſt; here follows another.

The deſertion of the lands employed in a trifling agriculture will at firſt, no doubt, embarraſs the farmers; but in a little time every thing becomes balanced in a trading nation, becauſe *here* every *induſtrious* man muſt advance in proſperity, in ſpite of all general combinations of circumſtances.

In the caſe before us, the relative profits upon farming muſt ſoon become greater than formerly, becauſe of this additional expence which muſt affect the whole claſs of farmers; conſequently, this additional expence, inſtead of turning out to be a loſs to either landlord or farmer, will, after ſome little time, turn out to the advantage of both: becauſe the produce of the ground, being indiſpenſably neceſſary to every body, muſt in every article increaſe in its value. Thus in a ſhort time accounts will be nearly balanced on all hands; that is to ſay, the ſame proportion of wealth will, *cæteris paribus*, continue the ſame among the induſtrious. We ſay among the induſtrious; for thoſe who are either idle, or even negligent, will be great loſers.

A proprietor of land, inattentive to the cauſes of his farmer's additional expence, may very imprudently ſuffer his rents to fall, inſtead of aſſiſting him on a proper occaſion, in order to make them afterwards riſe the higher.

Thoſe who live upon a determined income in money, and who are nowiſe employed in traffic, nor in any ſcheme of induſtry, will, by the augmentation of prices, be found in worſe circumſtances than before.

In a trading nation every man muſt turn his talents to account, or he will undoubtedly be left behind in this univerſal emulation, in which the moſt induſtrious, the moſt ingenious, and the moſt frugal will conſtantly carry off the prize.

This conſideration ought to be a ſpur to every body. The richeſt men in a trading nation have no ſecurity againſt poverty; we mean proportional poverty; for though they diminiſh nothing of their income, yet, by not increaſing it in proportion to others, they loſe their rank in wealth, and from the firſt claſs in which they ſtood they will ſlide inſenſibly down to a lower.

There is one conſequence of an additional beneficial trade, which raiſes demand and increaſes wealth; but if we ſuppoſe no proportional augmentation of ſupply, it will prove at beſt but an airy dream which laſts for a moment, and when the gilded ſcene is paſſed away, numberleſs are the inconveniencies which are ſeen to follow.

We ſhall now point out the natural conſequences of this augmentation of wealth drawn from foreign nations, when the ſtateſman remains inattentive to increaſe the ſupply both of food and manufactures, in proportion to the augmentation of mouths, and of the demand for the produce of induſtry.

In ſuch a ſituation profits will daily ſwell, and every ſcheme for reducing them within the bounds of moderation, will be looked upon as a hurtful and unpopular meaſure: be it ſo; but let us examine the conſequences.

We have ſaid, that the riſe of demand for manufactures naturally increaſes the value of work: now we muſt add, that under ſuch circumſtances, the augmentation of riches, *in a country, either not capable of improvement as to the ſoil, or where precautions have not been taken for facilitating a multiplication of inhabitants, by the importation of ſubſiſtence*, will be productive of the moſt calamitous conſequences.

On one ſide, this wealth will effectually diminiſh the maſs of the food before produced; and on the other, will increaſe the number of uſeleſs conſumers. The firſt of theſe circumſtances will raiſe the demand for food; and the ſecond will diminiſh the number of uſeful free hands, and conſequently raiſe the price of manufactures: here are ſhortly the outlines of this progreſs.

The more rich and luxurious a people are, the more delicate they become in their manner of living; if they fed on bread formerly, they will now feed on meat; if they fed on meat, they will now feed on fowl. The ſame ground which feeds a hundred with bread, and a proportional quantity of animal food, will not maintain an equal number of delicate livers. Food muſt then become more ſcarce; demand for it riſes; the rich are always the ſtrongeſt in the market; they conſume the food, and the poor are forced to ſtarve. Here the wide door to modern diſtreſs opens; to wit, a hurtful competition for ſubſiſtence. Farther, when a people become rich, they think leſs of œconomy; a number of uſeleſs ſervants are hired, to become an additional dead weight on conſumption; and when their ſtarving countrymen cannot ſupply the extravagance of the rich ſo cheaply as other nations, they either import inſtruments of foreign luxury, or ſeek to enjoy them out of their own country, and thereby make reſtitution of their gains.

Is it not therefore evident, that if, before things come to this paſs, additional ſubſiſtence be not provided by one method or other, the number of inhabitants muſt diminiſh; although riches may daily increaſe by a balance of additional matter, ſuppoſed to be brought into the country

in

in consequence of the hitherto beneficial foreign trade. This is not all. We say farther, that the beneficial trade will last for a time only. For the infallible consequence of the rise of prices at home will be, that those nations which at first consumed your manufactures, perceiving the gradual increase of their price, will begin to work for themselves; or finding out your rivals who can supply them cheaper, will open their doors to them. These again, perceiving the great advantages gained by your traders, will begin to supply the market; and since every thing must be cheaper in countries where we do not suppose the concurrence of all the circumstances mentioned above, these nations will supplant you, and be enriched in their turn.

Here comes a new revolution. Trade is come to a stop: what then becomes of all the hands which were formerly employed in supplying the foreign demands?

Were revolutions so sudden as we are obliged to represent them, all would go to wreck; in proportion as they happen by quicker or slower degrees, the inconveniencies are greater or smaller.

Prices, we have said, are made to rise by competition. If the competition of the strangers was what raised them, the distress upon the manufacturers will be in proportion to the suddenness of their deserting the market. If the competition was divided between the strangers and the home-consumers, the inconveniencies which ensue will be less; because the desertion of the strangers will be in some measure made up by an increase of home-consumption which will follow upon the fall of prices. And if, in the third case, the natives have been so imprudent, as not only to support a competition with the strangers, and thereby disgust them from coming any more to market, but even to continue the competition between themselves, the whole *loss* sustained by the revolution will be national. Wealth will cease to augment; but the inconveniencies, in place of being felt by the manufacturers, will only affect the state; those will continue in affluence, extolling the generosity of their countrymen, and despising the poverty of the strangers who had enriched them.

Domestic luxury will here prove an expedient for preserving from ruin the industrious part of a people, who in subsisting themselves had enriched their country. No change will follow in their condition; they will go on with a painful assiduity to labour, and if the consequences of it become now hurtful to one part of the state, they must at least be allowed to be essentially necessary for the support of the other.

But that luxury is no necessary concomitant of foreign trade, in a nation where the true principles of it are understood, will appear very plain, from a contrast we are now going to point out, in the example of a modern state, renowned for its commerce and frugality. The country is Holland.

A set of industrious and frugal people were assembled in a country by nature subject to many inconveniencies, the moving of which necessarily employed abundance of hands. Their situation upon the continent, the power of their former masters, and the ambition of their neighbours, obliged them to keep great bodies of troops. These two articles added to the numbers of the community, without either enriching the state by their labour exported, or producing food for themselves or countrymen.

The scheme of a commonwealth was calculated to draw together the industrious; but it has been still more useful in subsisting them: the republican form of government being there greatly subdivided, vests authority sufficient in every part of it, to make suitable provision for their own subsistence; and the tie which unites them, regards only matters of public concern. Had the whole been governed by one sovereign, or by one council, this important matter never could have been effectuated.

It would be impossible for the most able minister that ever lived, to provide nourishment for a country so extended as France, or even as England, supposing these as fully peopled as Holland is: even although it should be admitted that a sufficient quantity of food might be found in other countries for their subsistence. The enterprise would be too great, abuses would multiply; the consequence would be, that the inhabitants would die for want. But in Holland the case is different, every little town takes care of its own inhabitants; and this care being the object of application and profit to so many persons, is accomplished with success.

When once it is laid down as a maxim in a country, that food must of necessity be got from abroad in order to feed the inhabitants at home, the corn-trade becomes considerable, and at the same time certain, regular, and permanent. This was the case in Holland: as the inhabitants were industrious, the necessary consequence has been, a very extraordinary multiplication; and at the same time such an abundance of grain, that, instead of being in want themselves, they often supply their neighbours. There are many examples of England's being supplied with grain from thence, and, which is still more extraordinary, from the re-exportation of the very produce of its own fruitful soil.

It is therefore evident, that the only way to support industry, is to provide a supply of subsistence, constantly proportional to the demand that may be made for it. This is a precaution indispensably necessary for preventing hurtful competition. This is the particular care of the Dutch: so long as it can be effectual, their state can fear no decline; but whenever they come to be distressed in the markets, upon which they depend for subsistence, they will sink into ruin. It is by mere dint of frugality, cheap and parsimonious living, that the navigation of this industrious people is supported. Constant employment, and an accumulation of almost imperceptible gains, fills their coffers with wealth, in spite of the large outgoings to which their own proper nourishment yearly forces them. The large profits upon industry in other countries, which are no proof of generosity, but a fatal effect of a scanty subsistence, is far from dazzling their eyes. They seldom are found in the list of competitors at any foreign port; if they have their cargo to dispose of, they wait with pleasure in their own vessels, consuming their own provisions, and at last accept of what others have left. It may be said, that many other circumstances concur in favour of the Dutch, besides the article of subsistence.

 With-

Without disputing this matter, it may be observed, that if a computation be made of the hands employed in providing subsistence, and of those who are severally taken up in supplying every other want, their numbers will be found nearly to balance one another in the most luxurious countries. From this we may conclude, that the article of food, among the lower classes, must bear a very high proportion to all the other articles of their consumption; and therefore a diminution upon the price of subsistence, must be of infinite consequence to manufacturers, who are obliged to buy it. From this consideration, let us judge of the consequence of such augmentations upon the price of grain as are familiar to us; 30 or 40 *per cent.* seems nothing. Now this augmentation operates upon two thirds, at least, of the whole expence of a labouring man: let any one who lives in tolerable affluence make the application of this to himself, and examine how he would manage his affairs if, by accidents of rains or winds, his expences were to rise 30 *per cent.* without a possibility of restraining them; for this is unfortunately the case with all the lower classes. From whence it may be concluded, that the keeping food cheap, and still more the preserving it at all times at an equal standard, is the fountain of the wealth of Holland; and that any hurtful competition in this article must beget a disorder which will affect the whole of the manufacturers of a state.

COMMINATORY, an appellation given to whatever threatens punishment, or some penalty.

COMMINUTION, denotes the breaking, or rather grinding, a body to very small particles.

COMMISSARY, in the ecclesiastical law, an officer of the bishop, who exercises spiritual jurisdiction in places of a diocese so far from the episcopal see, that the chancellor cannot call the people to the bishop's principal consistory court, without giving them too much inconveniency.

COMMISSARY-*court*, in Scots law, a court originally constituted by the bishops for executing in their name an usurped jurisdiction, and was anciently called the *bishops court*, *curia Christianitatis*, or *consistorial court*. This court was new-modelled by Queen Mary at the Reformation, and continues till this day. See SCOTS LAW, title, *Ecclesiastical persons*.

COMMISSARY, in a military sense, is of three sorts.

COMMISSARY-*general of the musters*, an officer appointed to muster the army, as often as the general thinks proper, in order to know the strength of each regiment and company, to receive and inspect the muster-rolls, and to keep an exact state of the strength of the army.

COMMISSARY-*general of stores*, an officer in the artillery, who has the charge of all the stores, for which he is accountable to the office of ordnance.

COMMISSARY-*general of provisions*, an officer who has the inspection of the bread and provisions of the army.

COMMISSION, in common-law, the warrant or letters patent which all persons exercising jurisdiction have to empower them to hear or determine any cause or suit: as, the commission of the judges, &c.

COMMISSION *of bankruptcy*, is the commission that issues from the lord chancellor, on a person's becoming a bankrupt within any of the statutes, directed to certain commissioners appointed to examine into it, and to secure the bankrupt's lands and effects for the satisfaction of his creditors.

COMMISSION *of lunacy* issues out of the court of chancery, to inquire whether a person represented to be a lunatic be so or not.

COMMISSION, in commerce. See FACTORAGE.

COMMISSIONER, a person authorised by commission, letters-patent, or other lawful warrant, to examine any matters, or execute any public office, &c.

Besides those relating to judicial proceedings, there are

COMMISSIONERS *of the customs*. See CUSTOMS.

COMMISSIONERS *of excise*. See EXCISE.

COMMISSIONERS *of the navy*. See NAVY.

Lords COMMISSIONERS *of the treasury*. See TREASURY and EXCHEQUER.

COMMITTEE, one or more persons, to whom the consideration or ordering of a matter is referred, either by some court, or by the consent of parties, to whom it belongs.

COMMITTEE *of parliament*, a certain number of members appointed by the house, for the examination of a bill, making a report of an inquiry, process of the house, &c.

When a parliament is called, and the speaker and members have taken the oaths, there are committees appointed to sit on certain days, *viz.* the committee of privileges and elections, of religion, of trade, &c. which are standing committees.

Sometimes the whole house resolves itself into a committee; on which occasion each person has a right to speak and reply as often as he pleases, which is not the case when a house is not in a committee.

COMMIXTION, in Scots law, is a method of acquiring property, by mixing or blending together different substances belonging to different proprietors. If this commixtion was made without the consent of the different proprietors, and the materials cannot again be disjoined, it draws after it the property of the materials. See SCOTS LAW, title, *Division of rights*.

COMMODATE, in Scots law, is a gratuitous loan, wherein the property of the thing but continues with the lender, and only the use of it given to the borrower, who must restore the individual thing borrowed. See SCOTS LAW, title, *Obligations and contracts in general*.

COMMODITY, in a general sense, denotes all sorts of wares and merchandizes whatsoever that a person deals or trades in.

Staple COMMODITIES, such wares and merchandizes as are

are commonly and readily ſold in a market, or exported abroad: being, for the moſt part, the proper produce or manufacture of the country.

COMMODORE, in maritime affairs, an officer of the Britiſh navy, commiſſioned by the lords of the admiralty, or by an admiral, to command a ſquadron of men of war in chief.

COMMON, ſomething that belongs to all alike, in contradiſtinction to proper, peculiar, *&c.*

Common council. Council.

Common law, that body of rules received as law in England, before any ſtatute was enacted in parliament to alter the ſame. See Law.

Common-place book, is a regiſter of what things occur, worthy to be noted, in the courſe of a man's thinking or ſtudy, ſo diſpoſed, as that, among a number of ſubjects, any one may be eaſily found. The advantages of making a common-place book are many: it not only makes a man read with accuracy and attention, but induces him inſenſibly to think for himſelf, provided he conſiders it not ſo much as a regiſter of ſentiments that ſtrike him in the courſe of reading, but as a regiſter of his own thoughts upon various ſubjects. Many valuable thoughts occur even to men of no extraordinary genius. Theſe, without the aſſiſtance of a common place-book, are generally loſt both to himſelf and others. There are various methods of arranging common-place books; that of Mr Locke is as good as any that have hitherto been contrived.

The firſt page of the book you intend to take down their *common-place* in, is to ſerve as a kind of index to the whole; and to contain references to every place or matter therein: in the commodious contrivance of which index, ſo as it may admit of a ſufficient copia or variety of materials, without any confuſion, all the ſecret of the method conſiſts.

In order to this, the firſt page, as already mentioned, or, for more room, the two firſt pages that front each other, are to be divided, by parallel lines, into 25 equal parts; whereof, every fifth line to be diſtinguiſhed, by its colour or other circumſtance. Theſe lines are to be cut perpendicularly by others, drawn from top to bottom; and in the ſeveral ſpaces thereof, the ſeveral letters of the alphabet, both capital and minuſcule, are to be duly wrote.

The form of the lines and diviſions, both horizontal and perpendicular, with the manner of writing the letters therein, will be conceived from the following ſpecimen; wherein, what is to be done in the book for all the letters of the alphabet, is here ſhewn in the firſt four, *A*, *B*, *C*, and *D*.

	a			*a*	
	e			*e*	
A	*i*		*C*	*i*	
	o			*o*	
	u			*u*	
	a			*a*	
	e	2.3		*e*	
B	*i*		*D*	*i*	
	o			*o*	
	u			*u*	

The index of the *common-place* book thus formed, matters are ready for the taking down any thing therein.

In order to this, conſider to what head the thing you would enter is moſt naturally referred; and under which one would be led to look for ſuch a thing: in this head, or word, regard is had to the initial letter, and the firſt vowel that follows it; which are the characteriſtic letters whereon all the uſe of the index depends.

Suppoſe, (*e. gr.*) I would enter down a paſſage that refers to the head *Beauty*; *B*, I conſider, is the initial letter, and *e* the firſt vowel: then, looking upon the index for the partition *B*, and therein the line *e*, (which is the place for all words whoſe firſt letter is *B*, and firſt vowel *e*; as *Beauty*, *Beneficence*, *Bread*, *Breeding*, *Blemiſhes*,) and finding no numbers already down to direct me to any page of the the book where words of this characteriſtic have been entered, I turn forward to the firſt blank page I find, which, in a freſh book, as this is ſuppoſed to be, will be page 2, and here write what I have occaſion for on the head *Beauty*; beginning the head in the margin, and indenting all the other ſubſervient lines, that the head may ſtand out and ſhew itſelf: this done, I enter the page where it is wrote, *viz.* 2, in the index, in the ſpace, *B e*; from which time, the claſs *B e* becomes wholly in poſſeſſion of the 2d and 3d pages, which are conſigned to letters of this characteriſtic.

Had I found any page or number already entered in the ſpace *B e*, I muſt have turned to the page, and have wrote my matter in what room was left therein: ſo, if after entering the paſſage on beauty, I ſhould have occaſion for *benevolence*, or the like, finding the number 2 already poſſeſſed of the ſpace of this characteriſtic, I begin the paſſage on benevolence in the remainder of the page, which not containing the whole, I carry it on to page 3, which is alſo for *B e*; and add the number 3 in the index.

Common pleas is one of the king's courts now held conſtantly

constantly in Weftminfter hall, but in former times was moveable.

All civil caufes, as well real as perfonal, are, or, were formerly, tried in this court, according to the ftrict law of the land. In perfonal and mixed actions it has a concurrent jurifdiction with the king's bench, but has no cognizance of pleas of the crown. The actions belonging to the court of common pleas come thither by original, as arrefts and outlawries; or by privilege, or attachment for or againft privileged perfons; or out of inferior courts, not of record, by *pone, recordari, accedas ad curiam*, writ of falfe judgment, *&c*. The chief judge of this court is called lord chief juftice of the common pleas, who is affifted by three other judges: the other officers of the court are the *cuftos brevium*, who is the chief clerk; three prothonotaries, and their fecondaries; the clerk of the warrants, clerk of the effoins, fourteen filazers, four exigentors, a clerk of the juries, the chirographer, the clerk of the king's filver, clerk of the treafury, clerk of the feal, clerk of the outlawries, clerk of the inrolment of fines and recoveries, and clerk of the errors.

COMMON, in law, that foil, the ufe of which is common to this or that town or lordfhip. There is common of pafture for cattle, and alfo common of fifhing, common of eftovers, common of turbary, *&c*.

COMMON PRAYER is the liturgy in the church of England. Clergymen are to ufe the public form of prayers prefcribed by the Book of Common Prayer; and refufing to do fo, or ufing any other public prayers, are punifhable by 1 Eliz. c. ii.

COMMON, in grammar, denotes the gender of nouns, which are equally applicable to both fexes: thus *parens*, a parent, is of the common gender.

COMMON, in geometry, is applied to an angle, line, or the like, which belongs equally to two figures.

COMMON DIVISOR, a quantity or number which exactly divides two or more other quantities or numbers, without leaving any remainder.

COMMONER, or GENTLEMAN COMMONER, in the univerfities, a ftudent entered in a certain rank.

COMMONS, or HOUSE OF COMMONS a denomination given to the lower houfe of parliament. See PARLIAMENT.

COMMONS, or COMMONALTY, likewife fignifies the whole body of the people under the degree of a baron, whether knights, gentlemen, burgeffes, yeomen, *&c*.

Doctors COMMONS, See COLLEGE *of civilians*.

Proctor of the COMMONS. See PROCTOR.

COMMONTY, in Scots law, fometimes fignifies lands belonging to two or more common proprietors; fometimes a heath or muir though it fhould belong in property to one, if there has been a promifcuous poffeffion upon it by pafturage; and the act 1695 mentions *commonties* belonging in property to the king and to royal borroughs. See title, *Obligations arifing from confent*.

COMMONWEALTH. See REPUBLIC.

COMMUNICATION, in a general fenfe, the act of imparting fomething to another.

COMMUNICATION is alfo ufed for the connection of one thing with another, or the paffage from one place to another: thus a gallery is a communication between two apartments.

COMMUNICATION *of idioms*, in theology, the act of imparting the attributes of one of the natures in Jefus Chrift to the other.

COMMUNICATION *of motion*, the act whereby a body at reft is put into motion by a moving body; or, it is the acceleration of motion in a body already moving. See MECHANICS,

Lines of COMMUNICATION, in military matters, trenches made to continue and preferve a fafe correfpondence between two forts or pofts; or at a fiege, between two approaches, that they may relieve one another.

COMMUNION, in matters of religion, the being united in doctrine and difcipline; in which fenfe of the word, different churches are faid to hold communion with each other.

In the primitive chriftian church, every bifhop was obliged, after his ordination, to fend circular letters to foreign churches, to fignify that he was in communion with them. The three grand communions into which the Chriftian church is at prefent divided, is that of the church of Rome, the Greek church, and the Proteftant church: but originally all Chriftians were in communion with each other, having one common faith and difcipline.

COMMUNION is alfo ufed for the act of communicating in the facrament of the euchariſt, or the Lord's fupper. See RELIGION.

COMMUNION SERVICE, in the liturgy of the church of England, the office for the adminiftration of the holy facrament, extracted from feveral ancient liturgies, as thofe of St Bafil, St Ambrofe, *&c*.

By the laft rubric, part of this fervice is appointed to be read every funday and holyday, after the morning prayer, even though there be no communicants.

COMMUNITY, a fociety of men living in the fame place, under the fame laws, the fame regulations, and the fame cuftoms.

COMMUTATION, in law, the change of a penalty or punifhment from a greater to a lefs; as when death is commuted for banifhment, *&c*.

COMORIN, or CAPE COMORIN, the moft foutherly promontary of the hither India, lying north-weft of the ifland of Ceylon.

COMPACT, in phyfiology, is faid of bodies which are of a clofe, denfe, and heavy texture, with few pores, and very fmall.

COMPANY, in a commercial fenfe, is a fociety of merchants, mechanics, or other traders, joined together in one common intereft.

When there are only two or three joined in this manner, it is called a partnerfhip; the term *company* being reftrained to focieties confifting of a confiderable number of members, affociated together by a charter obtained from the prince.

The mechanics of all corporations, or towns incorporated, are thus erected into companies, which have charters of privileges and large immunities.

We

We ſhall here give ſome account of the principal companies of merchants, ſome of which trade with joint ſtocks, and all of them enjoy by charter many excluſive privileges: for however injurious theſe companies may, at this time of day, be reckoned to the nation in general, yet it is certain, that they were the original parents of all our foreign commerce; private traders upon their own bottom being diſcouraged from hazarding their fortunes in foreign countries, till the methods of traffic had been ſettled by joint-ſtock companies: and from this very principle it is, that we find ſeveral nations at preſent endeavouring to extend their trade by the ſame means. The moſt ancient trading company, in Britain, is the Hamburgh company, originally called merchants of the ſtaple, and afterwards merchant-adventurers: they were incorporated by king Edward IV. from which time they traded with ſucceſs till the reign of queen Elizabeth, who, for a farther encouragement of their induſtry, not only confirmed, but inlarged their privileges. However, it ought to be obſerved, that this trade is now open to private merchants, upon paying a very ſmall ſum to the company. The company of this kind, next incorporated, was that of the Ruſſia-merchants; who having improved their trade and commerce in thoſe remote parts, were incorporated by Edward VI. greatly encouraged by queen Mary, and had their confirmation, with an enlargement of their privileges, from Elizabeth. This company is not very conſiderable at preſent; the trade of thoſe parts being moſtly carried on by private merchants, on paying the ſum of 5 l. to the company.

The Eaſtland-company, formerly called merchants of Elbin, were encorporated by queen Elizabeth, and by her greatly encouraged; but, like the former company, it is now become inconſiderable, the trade of Norway and Sweden being laid open by act of parliament.

The Turkey, or Levant-company, was likewiſe incorporated by the ſame princeſs, and its charter confirmed and enlarged by king James I. who impowered them to trade to the Levant, or eaſtern parts of the Mediterranean; particularly to Smyrna, Aleppo, Alexandria, Grand-Cairo, and the other parts of the Turkiſh dominions. But this trade is now alſo laid open to private merchants, upon paying a ſmall conſideration.

The next in order is the Eaſt-India company, firſt incorporated in the year 1600, and impowered to trade to all countries lying eaſtward of the cape of Good Hope. Towards the end of king William's reign, an act of parliament paſſed, granting all private merchants, who ſhould raiſe a certain ſum for the ſupply of the government, the privilege of trading to theſe parts. Accordingly, a great many ſubſcribed, and were called the new Eaſt-India-company; which ſoon found it neceſſary to unite with the old one, and trade with one joint ſtock: ſince which time, they have been ſtyled the united Eaſt-India-company; and are at preſent in a flouriſhing condition, and in poſſeſſion of many conſiderable forts and factories on the coaſt of Malabar, the Coromandel-coaſt, the bay of Bengal, &c.

The royal African-company was firſt erected in the year 1661, with an excluſive privilege to trade from cape Blanc, on the coaſt of Africa, in 20° N. lat. as far as the cape of Good Hope. But this trade is now laid open by act of parliament.

The Eaſtland-company, the Greenland-company, the Hudſon's-bay-company, the South-ſea-company, have likewiſe their ſeveral charters and privileges for trading to the places from which they take their denominations.

Theſe are the principal trading company's belonging to the crown of Great Britain; and of a ſimilar nature are the Dutch Eaſt and Weſt India companies, the French Eaſt and Weſt India companies, &c.

Concerning theſe companies, it may be proper to remark, that however neceſſary they might be in the infancy of trade, they are now looked upon by moſt men in the light of monopolies: hence it is, that their privileges have from time to time been leſſened, in order to eſtabliſh an abſolutely free and general trade; and experience hath ſhewn, that the trade of the nation has advanced in proportion as monopolies have beed laid aſide. Indeed, to carry on trade with diſtant countries, where forces and forts are to be maintained, a company with a joint ſtock ſeems neceſſary; or, at leaſt, certain duties ought to be paid by all who trade thither, towards defraying the ſaid expences: for not to ſpeak of the Eaſt-India, Hudſon's bay, &c. companies, the expence of maintaining whoſe forts muſt be very conſiderable, even the Turkey, Hamburgh, Muſcovy, and Eaſtland companies, which do not trade with a joint ſtock, are nevertheleſs obliged to be at conſiderable charges, in making preſents to the grand ſeignior and his miniſters, maintaining conſuls, &c. It would therefore be injuſtice that any ſhould trade to the places within their charters, without paying the ſame duties towards the company's charge, as the preſent adventurers pay; but then there appears to be no reaſon why any of the king's ſubjects ſhould be barred from trading to thoſe places, or forced to pay a great fine for admiſſion, that are willing to pay the company's duties, and ſubmit to their regulations and orders in other reſpects.

On the whole, as all reſtrictions of trade are found to be hurtful, nothing can be more evident than that no company whatſoever, whether they trade in a joint ſtock, or only under regulation, can be for the public good, except it may be eaſy for all or any of his majeſty's ſubjects to be admitted into all or any of the ſaid companies, at any time, and for a very inconſiderable fine.

Company, in military affairs, a ſmall body of foot, commanded by a captain, who has under him a lieutenant and enſign.

The number of centinels or private ſoldiers in a company, may be from 50 to 80; and a battalion conſiſts of thirteen ſuch companies, one of which is always grenadiers, and poſted on the right: next them ſtand the eldeſt company, and on the left the ſecond company; the

the youngeſt one being always poſted in the centre.

Companies not incorporated into regiments are called irregulars, or independent companies.

Artillery COMPANY. See ARTILLERY.

COMPANY *of ſhips*, a fleet of merchantmen, who make a charter-party among themſelves; the principal conditions whereof uſually are, that certain veſſels ſhall be acknowledged admiral, vice-admiral, and rear-admiral; that ſuch and ſuch ſignals ſhall be obſerved; that thoſe which bear no guns, ſhall pay ſo much *per cent.* of their cargo; and in caſe they be attacked, that what damages are ſuſtained, ſhall be reimburſed by the company in general. In the Mediterranean, ſuch companies are called conſerves.

COMPARATIVE ANATOMY, is that branch of anatomy which conſiders the ſecondary objects, or the bodies of other animals; ſerving for the more accurate diſtinctions of ſeveral parts, and ſupplying the defect of human ſubjects.

It is otherwiſe called the anatomy of beaſts, and ſometimes zootomy; and ſtands in contradiſtinction to human anatomy, or that branch of the art which conſiders the human body, the primary object of anatomy. See ANATOMY.

COMPARATIVE DEGREE, among grammarians, that between the poſitive and ſuperlative degrees, expreſſing any particular quality above or beneath the level of another.

COMPARISON, in a general ſenſe, the conſideration of the relation between two perſons or things, when oppoſed and ſet againſt each other, by which we judge of their agreement or difference.

Inſtruction is the principal, but not the only end of compariſon. It may be employed with ſucceſs in putting a ſubject in a ſtrong point of view. A lively idea is formed of a man's courage by likening it to that of a lion; and eloquence is exalted in our imagination by comparing it to a river overflowing its bank, and involving all in its impetuous courſe. The ſame effect is produced by contraſt: A man in proſperity becomes more ſenſible of his bapppineſs, by comparing his condition with that of a perſon in want of bread. Thus compariſon is ſubſervient to poetry as well as to philoſophy.

Compariſons ſerve two purpoſes: when addreſſed to the underſtanding, their purpoſe is to inſtruct; when to the heart, their purpoſe is to pleaſe. Various means contribute to the latter: firſt, the ſuggeſting ſome unuſual reſemblance or contraſt; ſecond, the ſetting an object in the ſtrongeſt light; third, the aſſociating an object with others that are agreeable; fourth, the elevating an object; and, fifth, the depreſſing it. And that compariſons may give pleaſure by theſe various means, will be made evident by examples, which ſhall be given, after premiſing ſome general obſervations.

Objects of different ſenſes cannot be compared together; for ſuch objects are totally ſeparated from each other, and have no circumſtance in common to admit either reſemblance or contraſt. Objects of hearing may be compared together, as alſo of taſte, of ſmell, and of touch: but the chief fund of compariſon are objects of ſight; becauſe, in writing or ſpeaking, things can only be compared in idea, and the ideas of ſight are more diſtinct and lively than thoſe of any other ſenſe.

When a nation emerging out of barbarity begins to think of the fine arts, the beauties of language cannot long lie concealed; and when diſcovered, they are generally, by the force of novelty, carried beyond all bounds of moderation. Thus, in the earlieſt poems of every nation, we find metaphors and ſimiles founded on the ſlighteſt and moſt diſtant reſemblances, which, loſing their grace with their novelty, wear gradually out of repute; and now, by the improvement of taſte, no metaphor nor ſimile is admitted into any polite compoſition but of the moſt ſtriking kind. To illuſtrate this obſervation, a ſpecimen ſhall be given afterward of ſuch metaphors as we have been deſcribing: with reſpect to ſimiles take the following ſpecimen.

" Behold, thou art fair, my love: thy hair is as a
" flock of goats that appear from Mount Gilead: thy
" teeth are like a flock of ſheep from the waſhing, e-
" very one bearing twins: thy lips are like a thread
" of ſcarlet: thy neck like the tower of David built
" for an armoury, whereon hang a thouſand ſhields of
" mighty men: thy two breaſts like two young roes
" that are twins, which feed among the lilies: thy
" eyes like the fiſh-pools in Heſbon, by the gate of
" Bath-rabbin: thy noſe like the tower of Lebanon,
" looking toward Damaſcus." *Song of Solomon.*

" Thou art like ſnow on the heath; thy hair like
" the miſt of Cromla, when it curls on the rocks and
" ſhines to the beam of the weſt: thy breaſts are like
" two ſmooth rocks ſeen from Branno of the ſtreams:
" thy arms like two white pillars in the hall of the
" mighty Fingal." *Fingal.*

It has no good effect to compare things by way of ſimile that are of the ſame kind; nor to contraſt things of different kinds.

A numerous brigade haſten'd: as when bands
Of pioneers with ſpade and pick-ax arm'd,
Forerun the royal camp to trench a field
Or caſt a rampart. *Milton.*

The following is of things contraſted that are of different kinds.

Queen. What, is my Richard both in ſhape and mind
Transform'd and weak? Hath Bolingbroke depos'd
Thine intellect? Hath he been in thy heart?
The lion, dying, thruſteth forth his paw,
And wounds the earth, if nothing elſe, with rage
To be o'erpower'd: and wilt thou, pupil like,
Take thy correction mildly, kiſs the rod,
And fawn on rage with baſe humility?
Richard II. *act* 5. *ſc.* 1.

This compariſon has ſcarce any force: a man and a lion are of different ſpecies, and therefore are proper ſubjects for a ſimile; but there is no ſuch reſemblance between them in general, as to produce any ſtrong effect by contraſting particular attributes or circumſtances.

A third general obſervation is, That abſtract terms

can never be the ſubject of compariſon, otherwiſe than by being perſonified. Shakeſpear compares adverſity to a toad, and ſlander to the bite of a crocodile; but in ſuch compariſons theſe abſtract terms muſt be imagined ſenſible beings.

To have a juſt notion of compariſons, they muſt be diſtinguiſhed into two kinds; one common and familiar, as where a man is compared to a lion in courage, or to a horſe in ſpeed; the other more diſtant and refined, where two things that have in themſelves no reſemblance or oppoſition, are compared with reſpect to their effects. There is no reſemblance between a flower-plot and a chearful ſong; and yet they may be compared with reſpect to their effects, the emotions they produce in the mind being extremely ſimilar. There is as little reſemblance between fraternal concord and precious ointment; and yet obſerve how ſucceſsfully they are compared with reſpect to the impreſſions they make.

"Behold, how good and how pleaſant it is for "brethren to dwell together in unity. It is like the "precious ointment upon the head, that ran down "upon Aaron's beard, and deſcended to the ſkirts of "his garment." *Pſalm* 133.

For illuſtrating this ſort of compariſon, we ſhall add ſome more examples:

"Delightful is thy preſence, O Fingal! it is like "the ſun on Cromla, when the hunter mourns his "abſence for a ſeaſon, and ſees him between the "clouds.

"Did not Oſſian hear a voice? or is it the ſound "of days that are no more? Often, like the even-"ing-ſun, comes the memory of former times on my "ſoul.

"His countenance is ſettled from war; and is calm "as the evening-beam, that from the cloud of the "weſt looks on Cona's ſilent vale." *Fingal.*

We now proceed to illuſtrate by particular inſtances the different means by which compariſons, whether of the one ſort or the other, can afford pleaſure; and, in the order above eſtabliſhed, we ſhall begin with ſuch inſtances as are agreeable by ſuggeſting ſome unuſual reſemblance or contraſt.

Sweet are the uſes of Adverſity,
Which, like the toad, ugly and venomous,
Wears yet a precious jewel in her head.
As you like it, act 2. *ſc.* 1.

See, how the Morning opes her golden gates,
And takes her farewel of the glorious ſun;
How well reſembles it the prime of youth,
Trimm'd like a yonker prancing to his love.
Second Part Henry VI. *act.* 2. *ſc.* 1.

Thus they their doubtful conſultations dark
Ended, rejoicing in their matchleſs chief:
As when from mountain tops, the duſky clouds
Aſcending, while the North-wind ſleeps, o'erſpread
Heav'n's chearful face, the lowring element
Scowls o'er the darken'd landſcape, ſnow, and ſhower;
If chance the radiant ſun with farewel ſweet
Extends his ev'ning-beam, the fields revive,
The birds their notes renew, and bleating herds
Atteſt their joy, that hill and valley rings.
Paradiſe Loſt, book 2.

None of the foregoing ſimiles tend to illuſtrate the principal ſubject: and therefore the chief pleaſure they afford muſt ariſe from ſuggeſting reſemblances that are not obvious: for undoubtedly a beautiful ſubject introduced to form the ſimile affords a ſeparate pleaſure, which is felt in the ſimiles mentioned, particularly in that cited from Milton.

The next effect of a compariſon in the order mentioned, is to place an object in a ſtrong point of view; which effect is remarkable in the following ſimiles.

As when two ſcales are charg'd with doubtful loads,
From ſide to ſide the trembling balance nods,
(While ſome laborious matron, juſt and poor,
With nice exactneſs weighs her woolly ſtore),
Till pois'd aloft, the reſting beam ſuſpends
Each equal weight; nor this nor that deſcends:
So ſtood the war, till Hector's matchleſs might,
With fates prevailing, turn'd the ſcale of fight.
Fierce as a whirlwind up the wall he flies,
And fires his hoſt with loud repeated cries.
Iliad, b. xii. 521.

——— Out, out, brief candle!
Life's but a walking ſhadow, a poor player,
That ſtruts and frets his hour upon the ſtage,
And then is heard no more.
Macbeath, act 5. *ſc.* 5.

O thou Goddeſs,
Thou divine nature! how thyſelf thou blazon'ſt
In theſe two princely boys! they are as gentle
As zephyrs blowing below the violet,
Not wagging his ſweet head; and yet as rough,
(Their royal blood inchaf'd) as the rud'ſt wind,
That by the top doth take the mountain-pine,
And make him ſtoop to th' vale.
Cymbeline, act 4. *ſc.* 4.

"Why did not I paſs away in ſecret, like the "flower of the rock that lifts its fair head unſeen, "and ſtrows its withered leaves on the blaſt?"
Fingal.

As words convey but a faint and obſcure notion of great numbers, a poet, to give a lively notion of the object he deſcribes with regard to number, does well to compare it to what is familiar and commonly known. Thus Homer compares the Grecian army in point of number to a ſwarm of bees: in another paſſage he compares it to that profuſion of leaves and flowers which appear in the ſpring, or of inſects in a ſummer's evening: and Milton,

————— As when the potent rod
Of Amram's ſon in Egypt's evil day
Wav'd round the coaſt, up call'd a pitchy cloud
Of locuſts, warping on the eaſtern wind,
That o'er the realm of impious Pharaoh hung
Like night, and darken'd all the land of Nile:
So numberleſs were thoſe bad angels ſeen,
Hov'ring on wing under the cope of hell,
'Twixt upper, nether, and ſurrounding fires.
Paradiſe Loſt, book 1.

Such comparisons have, by some writers, been condemned for the lowness of the images introduced: but surely without reason; for, with regard to numbers, they put the principal subject in a strong light.

Milton has a peculiar talent in embellishing the principal subject by associating it with others that are agreeable; which is the third end of a comparison. Similes of this kind have, beside, a separate effect: they diversify the narration by new images that are not strictly necessary to the comparison: they are short episodes, which, without drawing us from the principal subject, afford great delight by their beauty and variety.

He scarce had ceas'd, when the superior fiend
Was moving toward the shore; his pond'rous shield,
Ethereal temper, massy, large, and round,
Behind him cast; the broad circumference
Hung on his shoulders like the moon, whose orb
Through optic glass the Tuscan artist views
At ev'ning from the top of Fesole,
Or in Valdarno, to descry new lands,
Rivers, or mountains, in her spotty globe.

Milton, *b*. 1.

As when a vulture on Imaus bred,
Whose snowy ridge the roving Tartar bounds,
Dislodging from a region scarce of prey
To gorge the flesh of lambs, or yeanling kids,
On hills where flocks are fed, flies toward the springs
Of Ganges or Hydaspes, Indian streams,
But in his way lights on the barren plains
Of Sericana, where Chineses drive
With sails and wind their cany waggons light:
So on this windy sea of land, the fiend
Walk'd up and down alone, bent on his prey.

Milton *b*. 3.

Next of comparisons that aggrandise or elevate. These affect us more than any other sort: the reason of which will be evident from the following instances.

As when a flame the winding valley fills,
And runs on crackling shrubs between the hills,
Then o'er the stubble up the mountain flies,
Fires the high woods, and blazes to the skies,
This way and that, the spreading torrent roars;
So sweeps the hero through the wasted shores.
Around him wide, immense destruction pours,
And earth is delug'd with the sanguine show'rs.

Iliad xx. 569.

Methinks, King Richard and myself should meet
With no less terror than the elements
Of fire and water, when their thund'ring shock,
At meeting tears the cloudy cheeks of heaven.

Richard II. *act* 3. *sc*. 5.

"As rusheth a foamy stream from the dark shady
"steep of Cromla, when thunder is rolling above,
"and dark brown night rests on the hill: so fierce,
"so vast, so terrible, rush forward the sons of Erin.
"The chief, like a whale of Ocean followed by all
"its billows, pours valour forth as a stream, rolling
"its might along the shore." *Fingal*, *b*. 1.

The last article mentioned, is that of lessening or depressing a hated or disagreeable object; which is effectually done by resembling it to any thing low or despicable. Thus Milton, in his description of the rout of the rebel-angels, happily expresses their terror and dismay in the following simile:

——————— As a herd
Of goats or timorous flock together throng'd,
Drove them before him thunder-struck, pursu'd
With terrors and with furies to the bounds
And crystal wall of heav'n, which op'ning wide,
Rowl'd inward, and a spacious gap disclos'd
Into the wasteful deep; the monstrous sight
Strook them with horror backward, but far worse
Urg'd them behind; headlong themselves they threw
Down from the verge of Heav'n.

Milton, *b*. 6.

By this time the different purposes of comparison, and the various impressions it makes on the mind, are sufficiently illustrated by proper examples. This was an easy work. It is more difficult to lay down rules about the propriety or impropriety of comparisons; in what circumstances they may be introduced, and in what circumstances they are out of place. It is evident, that a comparison is not proper upon every occasion: a man in his cool and sedate moments, is not disposed to poetical flights, nor to sacrifice truth and reality to the delusive operations of the imagination: far less is he so disposed, when oppressed with care, or interested in some important transaction that occupies him totally. On the other hand, it is observable, that a man, when elevated or animated by any passion, is disposed to elevate or animate all his subjects: he avoids familiar names, exalts objects by circumlocution and metaphor, and gives even life and voluntary action to inanimate beings. In this warmth of mind, the highest poetical flights are indulged, and the boldest similes and metaphors relished. But without soaring so high, the mind is frequently in a tone to relish chaste and moderate ornament; such as comparisons that set the principal object in a strong point of view, or that embellish and diversify the narration. In general, when by any animating passion, whether pleasant or painful, an impulse is given to the imagination; we are in that condition disposed to every sort of figurative expression, and in particular to comparisons. This in a great measure is evident from the comparisons already mentioned; and shall be further illustrated by other instances. Love, for example, in its infancy, rousing the imagination, promps the heart to display itself in figurative language, and in similes:

Troilus. Tell me, Apollo, for thy Daphne's love,
What Cressid is, what Pandar, and what we?
Her bed is India, there she lies, a pearl:
Between our Ilium, and where she resides,
Let it be call'd the wild and wandering flood;
Ourself the merchant, and this sailing Pandar
Our doubtful hope, our convoy, and our bark.

Troilus and Cressida, *act* 1. *sc*. 1.

Again:

Come, gentle Night; come, loving black-brow'd Night!
Give me my Romeo; and, when he shall die,
Take him, and cut him out in little stars,
And he will make the face of heav'n so fine,

That

That all the world ſhall be in love with Night,
And pay no worſhip to the gariſh ſun.

Romeo and Juliet, act 3. ſc. 4.

But it will be a better illuſtration of the preſent head, to give examples where compariſons are improperly introduced. Similes are not the language of a man in his ordinary ſtate of mind, diſpatching his daily and uſual work: for that reaſon, the following ſpeech of a gardener to his ſervant, is extremely improper:

Go bind thou up yon dangling apricocks,
Which, like unruly children, make their ſire
Stoop with oppreſſion of their prodigal weight:
Give ſome ſupportance to the bending twigs.
Go thou, and, like an executioner,
Cut off the heads of too-faſt-growing ſprays,
That look too lofty in our commonwealth:
All muſt be even in our government.

Richard II. *act 3. ſc. 7.*

The fertility of Shakeſpear's vein betrays him frequently into this error.

Rooted grief, deep anguiſh, terror, remorſe, deſpair, and all the ſevere diſpiriting paſſions, are declared enemies, perhaps not to figurative language in general, but undoubtedly to the pomp and ſolemnity of compariſon. Upon this account, the ſimile pronounced by young Rutland, under terror of death from an inveterate enemy, and praying mercy, is unnatural:

So looks the pent-up lion o'er the wretch
That trembles under his devouring paws;
And ſo he walks inſulting o'er his prey,
And ſo he comes to rend his limbs aſunder.
Ah, gentle Clifford, kill me with thy ſword,
And not with ſuch a cruel threat'ning look.

Third part Henry VI. *act 1. ſc. 5.*

A man ſpent and diſpirited after loſing a battle, is not diſpoſed to heighten or illuſtrate his diſcourſe by ſimiles.

York. With this we charg'd again; but out! alas,
We bodg'd again; as I have ſeen a ſwan
With bootleſs labour ſwim againſt the tide,
And ſpend her ſtrength with over-matching waves.
Ah! hark, the fatal followers do purſue;
And I am faint and cannot fly their fury.
The ſands are number'd that make up my life;
Here muſt I ſtay, and here my life muſt end.

Third part Henry VI. *act 1. ſc. 6.*

Similes thus unſeaſonably introduced, are finely ridiculed in the *Rehearſal.*

" *Bayes.* Now here ſhe muſt make a ſimile.
" *Smith.* Where's the neceſſity of that, Mr Bayes?
" *Bayes.* Becauſe ſhe's ſurprized; that's a general
" rule; you muſt ever make a ſimile when you are
" ſurprized; 'tis a new way of writing."

A compariſon is not always faultleſs even where it is properly introduced. A compariſon, like other human productions, may fall ſhort of its end; of which defect inſtances are not rare even among good writers: and to complete the preſent ſubject, it will be neceſſary to make ſome obſervations upon ſuch faulty compariſons. Nothing can be more erroneous than to inſtitute a compariſon too faint: a diſtant reſemblance or contraſt fatigues the mind with its obſcurity, inſtead of amuſing it; and tends not to fulfil any one end of a compariſon. The following ſimiles ſeem to labour under this defect.

K. Rich. Give me the crown.—Here, couſin, ſeize the crown,
Here, on this ſide, my hand; on that ſide, thine.
Now is this golden crown like a deep well,
That owes two buckets, filling one another;
The emptier ever dancing in the air,
The other down, unſeen and full of water;
That bucket down, and full of tears, am I,
Drinking my griefs, whilſt you mount up on high.

Richard II. *act 4. ſc. 3.*

K. John. Oh! couſin, thou art come to ſet mine eye;
The tackle of my heart is crack'd and burnt;
And all the ſhrouds wherewith my life ſhould ſail,
Are turned to one thread, one little hair:
My heart hath one poor ſtring to ſtay it by,
Which holds but till thy news be uttered.

King John, act 5. ſc. 10.

York. My uncles both are ſlain in reſcuing me:
And all my followers to the eager foe
Turn back, and fly like ſhips before the wind,
Or lambs purſu'd by hunger-ſtarved wolves.

Third part Henry VI. *act 1. ſc. 6.*

The latter of the two ſimilies is good: the former, becauſe of the faintneſs of the reſemblance, produces no good effect, and crouds the narration with an uſeleſs image.

In an epic poem, or in any elevated ſubject, a writer ought to avoid raiſing a ſimile upon a low image, which never fails to bring down the principal ſubject. In general, it is a rule, that a grand object ought never to be reſembled to one that is diminutive, however delicate the reſemblance may be: for it is the peculiar character of a grand object to fix the attention, and ſwell the mind; in which ſtate, it is diſagreeable to contract the mind to a minute object, however elegant. The reſembling an object to one that is greater, has, on the contrary, a good effect, by raiſing or ſwelling the mind: for one paſſes with ſatisfaction from a ſmall to a great object; but cannot be drawn down, without reluctance, from great to ſmall. Hence the following ſimiles are faulty.

Meanwhile the troops beneath Patroclus' care,
Invade the Trojans, and commence the war.
As waſps, provok'd by children in their play,
Pour from their manſions by the broad highway,
In ſwarms the guiltleſs traveller engage,
Whet all their ſtings, and call forth all their rage;
All riſe in arms, and with a general cry
Aſſert their waxen domes and buzzing progeny:
Thus from the tents the fervent legion ſwarms,
So loud their clamours, and ſo keen their arms.

Iliad, xvi. 312.

So burns the vengeful hornet (ſoul all o'er)
Repuls'd in vain, and thirſty ſtill of gore;
(Bold ſon of air and heat) on angry wings
Untam'd, untir'd, he turns, attacks, and ſtings.

Fir'd with like ardour, fierce Atrides flew,
And fent his foul with ev'ry lance he threw.
Iliad, xvii. 642.

An error oppofite to the former, is the introducing a refembling image, fo elevated or great as to bear no proportion to the principal fubject. Their remarkable difparity, being the moft ftriking circumftance, feizes the mind, and never fails to deprefs the principal fubject by contraft, inftead of raifing it by refemblance: and if the difparity be exceeding great, the fimile takes on an air of burlefque; nothing being more ridiculous than to force an object out of its proper rank in nature, by equalling it with one greatly fuperior or greatly inferior. This will be evident from the following comparifon.

Loud as a bull makes hill and valley ring,
So roar'd the lock when it releas'd the fpring.
Odyffey, xxi. 51.

Such a fimile upon the fimpleft of all actions, that of opening a lock, is pure burlefque.

A writer of delicacy will avoid drawing his comparifons from any image that is naufeous, ugly, or remarkably difagreeable; for however ftrong the refemblance may be, more will be loft than gained by fuch comparifon. Therefore we cannot help condemning, though with fome reluctancy, the following fimile, or rather metaphor.

O thou fond many! with what loud applaufe
Did'ft thou beat heav'n with bleffing Bolingbroke
Before he was what thou would'ft have him be?
And now being trimm'd up in thine own defires,
Thou, beaftly feeder, art fo full of him,
That thou provok'ft thyfelf to caft him up.
And fo, thou common dog, didft thou difgorge
Thy glutton bofom of the royal Richard,
And now thou would'ft eat thy dead vomit up,
And howl'ft to find it.
Second part Henry IV. *act* 1. *fc*. 6.

The ftrongeft objection that can lie againft a comparifon is, that it confifts in words only, not in fenfe. Such falfe coin, or baftard wit, does extremely well in burlefque; but is far below the dignity of the epic, or of any ferious compofition:

The noble fifter of Poplicola,
The moon of Rome; chafte as the icicle
That's curdled by the froft from pureft fnow,
And hangs on Dian's temple.
Coriolanus, *act* 5. *fc*. 3.

There is evidently no refemblance between an icicle, and a woman, chafte or unchafte: but chaftity is cold in a metaphorical fenfe, and an icicle is cold in a proper fenfe; and this verbal refemblance, in the hurry and glow of compofing, has been thought a fufficient foundation for the fimile. Such phantom fimiles are mere witticifms, which ought to have no quarter, except where purpofely introduced to provoke laughter. Lucian, in his differtation upon hiftory, talking of a certain author, makes the following comparifon, which is verbal merely.

"This author's defcriptions are fo cold, that they "furpafs the Cafpian fnow, and all the ice of the "north."

——But for their fpirits and fouls
This word *rebellion* had froze them up
As fifh are in a pond.
Second part Henry IV. *act* 1. *fc*. 3.

Pope has feveral fimiles of the fame ftamp.

And hence one mafter paffion in the breaft,
Like Aaron's ferpent fwallows up the reft.
Epift. 2. *l*. 131.

And again, talking of this fame ruling or mafter paffion:

Nature its mother, Habit is its nurfe;
Wit, fpirit, faculties, but make it worfe;
Reafon itfelf but gives it edge and pow'r;
As heav'n's blefs'd beam turns vinegar more fowr.
Ibid, *l*. 145.

Where the fubject is burlefque or ludicrous, fuch fimiles are far from being improper. Horace fays pleafantly,

Quamquam tu levior cortice. *L*. 3. *od*. 9.

And Shakefpear,

In breaking oaths he's ftronger than Hercules.

And this leads to obferve, that befides the foregoing comparifons, which are all ferious, there is a fpecies, the end and purpofe of which is to excite gaiety or mirth. Take the following examples.

Falftaff, fpeaking to his page:

"I do here walk before thee, like a fow that hath "overwhelmed all her litter but one"
Second part Henry IV. *act* 1. *fc*. 10.

"I think he is not a pick-purfe, nor a horfe fteal"er; but for his verity in love, I do think him as "concave as a cover'd goblet, or a worm-eaten nut."
As you like it, *act* 3. *fc*. 10.

This fword a dagger had his page,
That was but little for his age;
And therefore waited on him fo,
As dwarfs upon knights-errant do.
Hudibras, *canto* 1.

"Books, like men, their authors, have but one "way of coming into the world; but there are ten "thoufand to go out of it, and return no more."
Tale of a Tub.

"The moft accomplifhed way of ufing books at "prefent is, to ferve them as fome do lords, learn "their *titles*, and then brag of their acquaintance."
Ibid.

"He does not confider, that fincerity in love is as "much out of fafhion as fweet fnuff; no body takes "it now." *Carelefs Hufband*.

Comparison *of ideas*, that operation of the mind whereby it compares its ideas one with another, in regard of extent, degree, time, place, or any other circumftance, and is the ground of relations.

Comparison, in grammar, the inflection of the comparative degree.

COMPARTITION, in architecture, denotes the ufeful and graceful difpofition of the whole ground-plot of an edifice, into rooms of office, and of reception or entertainment.

COMPARTMENT, in general, is a defign compofed of

of ſeveral different figures, diſpoſed with ſymmetry, to adorn a parterre, a ceiling, *&c.*

A compartment of tiles, or bricks, is an arrangement of them, of different colours, and varniſhed, for the decoration of a building. Compartments, in gardening, are an aſſemblage of beds, plats, borders, walks, *&c.* diſpoſed in the moſt advantageous manner that the ground will admit of. Compartments, in heraldry, are otherwiſe called partitions.

COMPASS, or *mariner's* COMPASS, an inſtrument whereby the ſhip's courſe is determined. See NAVIGATION.

Azimuth COMPASS. See NAVIGATION.

COMPASS *dials*, are ſmall horizontal dials, fitted in braſs or ſilver boxes, for the pocket, to ſhew the hour of the day, by the direction of a needle, that indicates how to place them right, by turning the dial about, till the cock or ſtyle ſtand directly over the needle, and point to the northward: but theſe can never be very exact, becauſe of the variations of the needle itſelf. See DIALING.

COMPASSES, or *pair of* COMPASSES, a mathematical inſtrument for deſcribing circles, meaſuring figures, *&c.*

The common compaſſes conſiſt of two ſharp-pointed branches, or legs, of iron, ſteel, braſs, or other metal, joined at top by a rivet, whereon they move as on a centre.

The principal perfection of this, as of all other compaſſes, conſiſts in the eaſy and uniform opening and ſhutting of their legs; one of which may be taken out, in order to make room for others.

There are now uſed compaſſes of various kinds and contrivances, accommodated to the various uſes they are intend d for.

COMPEIGN, a city of France, ſituated on the river Oyſe, about forty-five miles north-eaſt of Paris: E. long. 3°, N. lat. 49° 30′.

COMPENDIUM, in matters of literature, denotes much the ſame with epitome or abridgment. See ABRIDGMENT.

COMPENSATION, in a general ſenſe, an action whereby any thing is admitted as an equivalent to another.

COMPENSATION. Where the ſame perſon is debtor and creditor to another, the mutual obligations, if they are for equal ſums, are extinguiſhed by compenſation; if for unequal, the leſſer obligation is extinguiſhed, and the greater diminiſhed, as far as the concourſe of debt and credit goes. See SCOTS LAW, title, *Extinction of obligations.*

COMPETENCE, or COMPETENCY, in law, the right or authority of a judge, for taking cognizance of any matter.

COMPETITION, in Scots law: In eſcheats, ſee title, *Caſualties due to the ſuperior:* In confirmations by the ſuperior, in reſignations, and in perſonal rights of lands, ſee title, *Of tranſmiſſion of rights by confirmation:* In inhibitions, in adjudications, amongſt aſſignees, arreſters, and poinders, ſee title, *Inhibitions, adjudications, aſſignations, arreſtments, and poindings:* Amongſt creditors of a defunct, ſee title, *Succeſſion in moveables.*

COMPITALIA, or COMPITALITIA, in Roman antiquity, feaſts inſtituted by Servius Tullius in honour of the Lares. See LARES.

Theſe feaſts were obſerved on the 12th of January, and 6th of March.

COMPLEMENT, in geometry, is what remains of a quadrant of a circle, or of 90°, after any certain arch has been taken away from it. Thus, if the arch taken away be 40°, its complement is 50: becauſe $50+40=90$. The ſine of the complement of an arch is called the co-ſine, and that of the tangent the co-tangent, *&c.*

COMPLEX, in a more general ſenſe, a term ſynonymous with compound; though, in ſtrictneſs of ſpeech, there is ſome difference. See COMPOUND.

COMPLEX *terms*, or *ideas*, in logic, are ſuch as are compounded of ſeveral ſimple ones. See TERM, and IDEA.

COMPLEXION, among phyſicians, the temperament, habitude, and natural dipoſition of the body, but more often the colour of the face and ſkin.

COMPLEXUS, in anatomy. See Vol. I. p. 216.

COMPLEXUS *minor*, in anatomy. See Vol. I. p. 216.

COMPLICATION, in general, denotes the blending, or rather interweaving, of ſeveral different things together: thus a perſon afflicted with ſeveral diſorders at the ſame time, is ſaid to labour under a complication of diſeaſes.

COMPOUND, COMPONE, or GOBONY, in heraldry, is ſaid of a bordure made up of angular parts, or chequers, of two different colours. See Plate LXV. fig. 13.

COMPOSITE, in general, denotes ſomething compounded, or made up of ſeveral others united together. Thus,

COMPOSITE *numbers*, are ſuch as can be meaſured exactly by a number exceeding unity; as 6 by 2 or 3, or 10 by 5, *&c.* ſo that 4 is the loweſt compoſite number.

COMPOSITE *order*, in architecture. See Vol. I. p. 352.

COMPOSITION, in a general ſenſe, the uniting or putting together ſeveral things, ſo as to form one whole, called a compound.

COMPOSITION *of ideas*, an act of the mind, whereby it unites ſeveral ſimple ideas into one conception or complex idea.

When we are provided with a ſufficient ſtock of ſimple ideas, and have by habit and uſe rendered them familiar to our minds, they become the component parts of other ideas ſtill more complicated, and form what we may call a ſecond order of compound notions. This proceſs may be continued to any degree of compoſition we pleaſe, mounting from one ſtage to another, and enlarging the number of combinations.

COMPOSITION, in grammar, the joining of two words together; or prefixing a particle to another word, to augment, diminiſh, or change its ſignification.

COMPOSITION, in logic, a method of reaſoning, whereby

by we proceed from ſome general ſelf-evident truth, to other particular and ſingular ones.

In diſpoſing and putting together our thoughts, there are two ways of proceeding, equally within our choice: for we may ſo propoſe the truths, relating to any part of knowledge, as they preſented themſelves to the mind, in the manner of inveſtigation; carrying on the ſeries of proofs in a reverſe order, till they, at laſt, terminate in firſt principles: or beginning with theſe principles, we may take the contrary way, and from them deduce, by a direct train of reaſoning, all the ſeveral propoſitions we want to eſtabliſh.

This diverſity, in the manner of arranging our thoughts, gives riſe to the twofold diviſion of method eſtabliſhed among logicians; the one called analytic method, or the method of reſolution, inaſmuch as it traces things back to their ſource, and reſolves knowledge into its firſt and original principles. This method ſtands in contradiſtinction to the method of compoſition; or, as it is otherwiſe called, the ſynthetic method: for here we proceed by gathering together the ſeveral ſcattered parts of knowledge, and combining them into one ſyſtem, in ſuch a manner, as that the underſtanding is enabled diſtinctly to follow truth through all the different ſtages of gradation.

Composition, in muſic, the art of diſpoſing muſical ſounds into airs, ſongs, *&c.* either in one or more parts, to be ſung by a voice, or played on inſtruments. See Music, and Song.

Under compoſition are comprehended the rules, 1. Of melody, or the art of making a ſingle part; that is, contriving and diſpoſing the ſimple ſounds, ſo as that their ſucceſſion and progreſſion may be agreeable to the ear. See Melody.

2. Of harmony, or the art of diſpoſing and concerting ſeveral ſingle parts together, ſo as that they make one agreeable whole. See Harmony.

COMPOSITION, in literature, the art of forming and arranging ſentiments, and cloathing them with language ſuitable to the nature of the ſubject or diſcourſe. We ſhall firſt give a few thoughts on original compoſition; and, 2dly, by way of example, unfold the nature of epic and dramatic compoſitions.

1. *On Original Compoſition.*

The mind of a man of genius is a fertile and pleaſant field; pleaſant as *Elyſium*, and fertile as *Tempe*; it enjoys a perpetual ſpring. Of that ſpring, *originals* are the faireſt flowers: *imitations* are of quicker growth, but fainter bloom. *Imitations* are of two kinds; one of nature, one of authors: the firſt we call *originals*, and confine the term *imitation* to the ſecond. We ſhall not enter into the curious inquiry of what is, or is not, ſtrictly ſpeaking, *original*, content with what all muſt allow, that ſome compoſitions are more ſo than others; and the more they are ſo, the better. *Originals* are, and ought to be, great favourites, for they are benefactors; they extend the republic of letters, and add a new province to its dominion: *imitators* only give us a ſort of duplicates of what we had, poſſibly much better, before; increaſing the mere drug of books, while all that makes them valuable, *knowledge* and *genius*, are at a ſtand. The pen of an *original* writer, like Armida's wand, out of a barren waſte calls a blooming ſpring: out of that blooming ſpring an *imitator* is a tranſplanter of laurels, which ſometimes die on removal, always languiſh in a foreign ſoil.

But ſuppoſe an *imitator* to be moſt excellent (and ſuch there are), yet ſtill he but nobly builds on another's foundation; his debt is, at leaſt, equal to his glory; which therefore, on the balance, cannot be very great. On the contrary, an *original*, though but indifferent (its *originality* being ſet aſide), yet has ſomething to boaſt; it is ſomething to ſay with him in Horace,

Meo *ſum pauper in ære*;

and to ſhare ambition with no leſs than *Cæſar*, who declared he had rather be the firſt in a village, than the ſecond at Rome.

Still farther: an *imitator* ſhares his crown, if he has one, with the choſen object of his imitation; an *original* enjoys an undivided applauſe. An *original* may be ſaid to be of a *vegetable* nature; it riſes ſpontaneouſly from the vital root of genius; it *grows*, it is not *made*: *imitations* are often a ſort of *manufacture* wrought by thoſe *mechanics*, *art* and *labour*, out of pre-exiſtent materials not their own.

Again: we read *imitation* with ſomewhat of his languor who liſtens to a twice-told tale: our ſpirits rouſe at an *original*; that is a perfect ſtranger, and all throng to learn what news from a foreign land: and though it comes, like an Indian prince, adorned with feathers only, having little of weight; yet of our attention it will rob the more ſolid, if not equally new: thus every teleſcope is lifted at a new-diſcovered ſtar; it makes a hundred aſtronomers in a moment, and denies equal notice to the ſun. But if an *original*, by being as excellent, as new, adds admiration to ſurprize, then are we at the writer's mercy; on the ſtrong wing of his imagination, we are ſnatched from Britain to Italy, from climate to climate, from pleaſure to pleaſure; we have no home, no thought, of our own; till the magician drops his pen: and then falling down into ourſelves, we awake to flat realities, lamenting the change, like the beggar who dreamt himſelf a prince.

It is with thoughts, as it is with words; and with both, as with men; they may grow old and die. Words tarniſhed, by paſſing through the mouths of the vulgar, are laid aſide as inelegant and obſolete. So thoughts, when become too common, ſhould loſe their currency; and we ſhould ſend new metal to the mint, that is, new meaning to the preſs. The diviſion of tongues at Babel did not more effectually debar men from making themſelves a name (as the ſcripture ſpeaks) than the too great concurrence or union of tongues will do for ever. We may as well grow good by another's virtue, or fat by another's food, as famous by another's thought. The world will pay its debt of praiſe but once; and inſtead of applauding, explode a ſecond demand, as a cheat.

If it is ſaid, that moſt of the Latin claſſics, and all the Greek, except, perhaps, Homer, Pindar, and Anacreon,

creon, are in the number of *imitators*, yet receive our higheſt applauſe; our anſwer is, that they, though not *real*, are *accidental originals*; the works they imitated, few excepted, are loſt: they, on their father's deceaſe, enter as lawful heirs on their eſtates in fame: the fathers of our copyiſts are ſtill in poſſeſſion; and ſecured in it, in ſpite of Goths, and flames, by the perpetuating power of the preſs. Very late muſt a modern *imitator*'s fame arrive, if it waits for their deceaſe.

An *original* enters early on reputation: *fame*, fond of new glories, ſounds her trumpet in triumph at its birth; and yet how few are awakened by it into the noble ambition of like attempts? Ambition is ſometimes no vice in life; it is always a virtue in compoſition. High in the towering Alps is the fountain of the Po; high in fame, and in antiquity, is the fountain of an *imitator*'s undertaking; but the river, and the imitation, humbly creep along the vale. So few are our *originals*, that, if all other books were to be burnt, the lettered world would reſemble ſome metropolis in flames, where a few incombuſtible buildings, a fortreſs, temple, or tower, lift their heads, in melancholy grandeur, amid the mighty ruin. Compared with this conflagration, old Omar lighted up but a ſmall bonfire, when he heated the baths of the barbarians, for eight months together, with the famed Alexandrian library's ineſtimable ſpoils, that no prophane book might obſtruct the triumphant progreſs of his holy Alcoran round the globe.

But why are originals ſo few? not becauſe the writer's harveſt is over, the great reapers of antiquity having left nothing to be gleaned after them; nor becauſe the human mind's teeming time is paſt, or becauſe it is incapable of putting forth unprecedented births; but becauſe illuſtrious examples *engroſs*, *prejudice*, and *intimidate*. They *engroſs* our attention, and ſo prevent a due inſpection of ourſelves; they *prejudice* our judgment in favour of their abilities, and ſo leſſen the ſenſe of our own; and they *intimidate* us with the ſplendor of their renown, and thus under diffidence bury our ſtrength. Nature's impoſſibilities, and thoſe of diffidence, lie wide aſunder.

After all, the firſt ancients had not merit in being *originals*: they could *not* be *imitators*. Modern writers have a *choice* to make; and therefore have a merit in their power. They may ſoar in the regions of *liberty*, or move in the ſoft fetters of eaſy *imitation*; and *imitation* has as many plauſible reaſons to urge, as *pleaſure* had to offer to Hercules. Hercules made the choice of an hero, and *ſo* became immortal.

Yet let not aſſertors of claſſic excellence imagine, that we deny the tribute it ſo well deſerves. He that admires not ancient authors, betrays a ſecret he would conceal, and tells the world, that he does not underſtand them. Let us be as far from neglecting, as from copying, their admirable compoſitions: ſacred be their rights, and inviolable their fame. Let our underſtanding feed on theirs; they afford the nobleſt nouriſhment: but let them nouriſh, and annihilate, our own. When we read, let our imagination kindle at their charms; when we write, let our judgment ſhut them out of our thoughts; treat even Homer himſelf, as his royal admirer was treated by the cynic; bid him ſtand aſide, nor ſhade our compoſition from the beams of our own genius; for nothing *original* can riſe, nothing immortal, can ripen, in any other ſun.

Muſt we, then, not imitate ancient authors? Imitate them, by all means; but imitate aright. He that imitates the divine Iliad, does not imitate Homer; but he who takes the ſame method, which Homer took, for arriving at a capacity of accompliſhing a work ſo great. Tread in his ſteps to the ſole fountain of immortality; drink where he drank, at the true *Helicon*, that is, at the breaſt of nature. Imitate; but imitate not the *compoſition*, but the *man*. For may not this paradox paſs into a maxim? *viz.* "The leſs we copy the renowned ancients, we ſhall reſemble them the more."

But poſſibly it may be replied, that we muſt either imitate Homer, or depart from nature. Not ſo: for ſuppoſe you was to change place, in time, with Homer; then, if you write naturally, you might as well charge Homer with an imitation of you. Can you be ſaid to imitate Homer for writing *ſo*, as you would have written if Homer had never been? As far as a regard to nature, and ſound ſenſe, will permit a departure from your great predeceſſors; ſo far, ambitiouſly, depart from them; the farther from them in *ſimilitude*, the nearer are you to them in *excellence*; you riſe by it into an *original*; become a noble collateral, not an humble deſcendant from them. Let us build our compoſitions with the ſpirit, and in the taſte of the ancients; but not with their materials: thus will they reſemble the ſtructures of Pericles at Athens, which Plutarch commends for having had an air of antiquity as ſoon as they were built. All eminence, and diſtinction, lies out of the beaten road; excurſion, and deviation, are neceſſary to find it; and the more remote your path from the highway, the more reputable; if, like poor Gulliver, you fall not into a ditch, in your way to glory.

What glory to come near, what glory to reach, what glory (preſumptuous thought!) to ſurpaſs our predeceſſors? And is that then in nature abſolutely impoſſible? or is it not rather contrary to nature to fail in it? Nature herſelf ſets the ladder, all wanting is our ambition to climb. For by the bounty of nature we are as ſtrong as our predeceſſors; and by the favour of time (which is but another round in nature's ſcale) we ſtand on higher ground. As to the *firſt*, were *they* more than men? or are *we* leſs? Are not our minds caſt in the ſame mould with thoſe before the flood? The flood affected matter: mind eſcaped. As to the *ſecond*; though we are moderns, the world is an ancient; more ancient far, than when they, whom we moſt admire, filled it with their fame. Have we not their beauties, as ſtars, to guide; their defects, as rocks, to be ſhunned; the judgment of ages on both, as a chart to conduct, and a ſure helm to ſteer us in our paſſage to greater perfection than theirs? And ſhall we be ſtopt in our rival pretenſions to fame by this juſt reproof?

Stat contra, dicitque tibi tua pagina, Fur *es.*
MART.

It is by a ſort of noble contagion, from a general familiarity with their writings, and not by any particular ſordid theft, that we can be the better for thoſe who went

went before us. Hope we, from plagiarifm, any dominion in literature; as that Rome rofe from a neft of thieves?

Rome was a powerful ally to many ftates; ancient authors are our powerful allies; but we muft take heed, that they do not fuccour till they inflave, after the manner of Rome. Too formidable an idea of their fuperiority, like a fpectre, would fright us out of a proper ufe of our wits; and dwarf our underftanding, by making a giant of theirs. Too great awe for them lays genius under reftraint, and denies it that free fcope, that full elbow-room, which is requifite for ftriking its moft mafterly ftrokes. Genius is a mafter-workman, learning is but an inftrument, and an inftrument, though moft valuable, yet not always indifpenfable. Heaven will not admit of a partner in the accomplifhment of fome favourite fpirits; but rejecting all human means, affumes the whole glory to itfelf. Have not fome, though not famed for erudition, *fo* written, as almoft to perfuade us, that they fhone brighter, and foared higher, for efcaping the boafted aid of that proud ally?

Nor is it ftrange; for what, for the moft part, mean we by genius, but the power of accomplifhing great things without the means generally reputed neceffary to that end? A *genius* differs from a *good underftanding*, as a magician from a good architect; *that* raifes his ftructure by means invifible; *this* by the fkilful ufe of common tools. Hence genius has ever been fuppofed to partake of fomething divine.

Learning, deftitute of this fuperior aid, is fond, and proud of what has coft it much pains; is a great lover of rules, and boafter of famed examples. As beauties lefs perfect, who owe half their charms to cautious art, learning inveighs againft natural unftudied graces, and fmall harmlefs inaccuracies, and fets rigid bounds to that liberty to which genius often owes its fupreme glory; but the no genius its frequent ruin. For unprefcribed beauties, and unexampled excellence, which are characteriftics of *genius*, lie without the pale of *learning*'s authorities, and laws; which pale, genius muft leap to come at them: but by that leap, if genius is wanting, we break our necks; we lofe that little credit, which poffibly we might have enjoyed before. For rules, like crutches, are a needful aid to the lame, though an impediment to the ftrong. A Homer cafts them away; and, like his Achilles,

Jura negat fibi nata, nihil non arrogat,

by native force of mind. There is fomething in poetry beyond profe-reafon; there are myfteries in it not to be explained, but admired; which render mere profe-men infidels to their divinity. And here may be offered a fecond paradox: *viz.* "*Genius* often then deferves moft to be praifed, when it is moft fure to be condemned; that is, when its excellence, from mounting high, to weak eyes is quite out of fight."

If we might fpeak farther of learning and genius, we would compare genius to virtue, and learning to riches. As riches are moft wanted where there is leaft virtue; fo learning where there is leaft genius. As virtue without much riches can give happinefs; fo genius without much learning can give renown. As it is faid in Terence, *pecuniam negligere interdum maximum eft lucrum;* fo to neglect of learning, genius fometimes owes its greater glory. Genius, therefore, leaves but the fecond place, among men of letters, to the learned. It is their merit, and ambition, to fling light on the works of genius, and point out its charms. We moft juftly reverence their informing radius for that favour; but we muft much more admire the radiant ftars pointed out by them.

A ftar of the firft magnitude among the moderns was Shakefpeare; among the ancients, Pindar; who, (as Voffius tells us) boafted of his no learning, calling himfelf the eagle, for his flight above it. And fuch genii as thefe may, indeed, have much reliance on their own native powers. For genius may be compared to the natural ftrength of the body; learning to the fuperinduced accountrements of arms: if the firft is equal to the propofed exploit, the latter rather encumbers, than affifts; rather retards, than promotes, the victory. *Sacer nobis ineft Deus*, fays Seneca. With regard to the moral world, *confcience*, with regard to the intellectual, *genius*, is that god within. Genius can fet us right in compofition, without the rules of the learned; as confcience fets us right in life, without the laws of the land: *this*, fingly, can make us good, as men: *that*, fingly, as writers, can, fometimes, make us great

As too great admirers of the fathers of the church have fometimes fet up their authority againft the true fenfe of fcripture; fo too great admirers of the claffical fathers have fometimes fet up their authority, or example, againft reafon.

Neve minor, neu fit quinto productior actu fabula.

So fays Horace, fo fays ancient example. But reafon has not fubfcribed. We know but one book that can juftify our implicit acquiefcence in it: and (by the way) on that book a noble difdain of undue deference to prior opinion has lately caft, and is ftill cafting, a new and ineftimable light.

But, fuperftition for our predeceffors fet afide, the claffics are for ever our rightful and revered mafters in *compofition*; and our underftandings bow before them. But when? When a mafter is wanted; which fometimes is not the cafe. Some are pupils of nature only, nor go farther to fchool. From fuch we reap often a double advantage; they not only rival the reputation of the great ancient authors, but alfo reduce the number of mean ones among the moderns. For when they enter on fubjects which have been in former hands, fuch is their fuperiority, that, like a tenth wave, they overwhelm, and bury in oblivion all that went before: and thus not only enrich and adorn, but remove a load, and leffen the labour, of the letter'd world.

"But, it may be faid, fince *originals* can arife from genius only, and fince genius is fo very rare, it is fcarce worth while to labour a point fo much, from which we can reafonably expect fo little." To fhow that genius is not fo very rare as you imagine, we fhall point out ftrong inftances of it, in a far diftant quarter from that mentioned above. The minds of the fchoolmen were almoft as much cloiftered as their bodies; they had but little learning, and few books; yet may the moft learned be ftruck with

with ſome aſtoniſhment at their ſo ſingular natural ſagacity, and moſt exquiſite edge of thought. Who would expect to find Pindar and Scotus, Shakeſpeare and Aquinas, of the ſame party? Both equally ſhew an *original*, unindebted, energy: the *vigor igneus*, and *cæleſtis origo*, burns in both; and leaves us in doubt whether genius is more evident in the ſublime flights and beauteous flowers of poetry, or in the profound penetrations, and marvelouſly keen and minute diſtinctions, called the thorns of the ſchools. There might have been more able conſuls called from the plough, than ever arrived at that honour: many a genius, probably, there has been, which could neither write nor read. So that genius, that ſupreme luſtre of literature, is leſs rare than is generally conceived.

By the praiſe of genius we detract not from learning; we detract not from the value of gold, by ſaying that diamond has greater ſtill. He who diſregards learning, ſhows that he wants its aid; and he that overvalues it, ſhows that its aid has done him harm. Over-valued indeed it cannot be, if genius as to *compoſition*, is valued more. Learning, we thank; genius, we revere; that gives us pleaſure, this gives us rapture; that informs, this inſpires; and is itſelf inſpired; for genius is from heaven, learning from man: *this* ſets us above the low, and illiterate; *that*, above the learned, and polite. Learning is borrowed knowledge; genius is knowledge innate, and quite our own. Therefore, as Bacon obſerves, it may take a nobler name, and be called wiſdom; in which ſenſe of wiſdom, ſome are born wiſe.

Having put in a caveat againſt the moſt fatal of errors, from the too great indulgence of genius, return we now to that too great ſuppreſſion of it, which is detrimental to compoſition; and endeavour to reſcue the writer, as well as the man. We have ſaid, that ſome are born wiſe; but they, like thoſe that are born rich, by neglecting the cultivation and produce of their own poſſeſſions, and by running in debt, may be beggared at laſt; and loſe their reputations, as younger brothers eſtates, not by being born with leſs abilities than the rich heir, but at too late an hour.

Many a great man has been loſt to himſelf, and the public, purely becauſe great ones were born before him. Hermias, in his collections on Homer's blindneſs, ſays, that Homer requeſting the gods to grant him a ſight of Achilles, that hero roſe, but in armour ſo bright, that it ſtruck Homer blind with the blaze. Let not the blaze of even Homer's muſe darken us to the diſcernment of our own powers; which may poſſibly ſet us above the rank of *imitators*; who, though moſt excellent, and even immortal, (as ſome of them are), yet are ſtill but *dii minorum gentium*, nor can expect the largeſt ſhare of incenſe, the greateſt profuſion of praiſe, on their ſecondary altars.

But farther ſtill: a ſpirit of *imitation* hath many ill effects; we ſhall confine ourſelves to three. *Firſt*, It deprives the liberal and politer arts of an advantage which the mechanic enjoy: in theſe, men are ever endeavouring to go beyond their predeceſſors; in the former, to follow them. And ſince copies ſurpaſs not their *originals*, as ſtreams riſe not higher than their ſpring, rarely ſo high; hence, while arts mechanic are in perpetual progreſs and increaſe, the liberal are in retrogradation and decay. *Theſe* reſemble pyramids, are broad at bottom, but leſſen exceedingly as they riſe; *thoſe* reſemble rivers, which, from a ſmall fountain head, are ſpreading ever wider and wider, as they run. Hence it is evident, that different portions of underſtanding are not (as ſome imagine) allotted to different periods of time; for we ſee, in the ſame period, underſtanding riſing in one ſet of artiſts, and declining in another. Therefore, *nature* ſtands abſolved, and our inferiority in compoſition muſt be charged on ourſelves.

Nay, ſo far are we from complying with a neceſſity which nature lays us under, that, *ſecondly*, by a ſpirit of imitation we counteract nature, and thwart her deſign. She brings us into the world all *originals*. No two faces, no two minds, are juſt alike; but all bear nature's evident mark of ſeparation on them. Born *originals*, how comes it to paſs that we die *copies?* That meddling ape *imitation*, as ſoon as we come to years of *indiſcretion*, (if we may ſo ſpeak), ſnatches the pen, and blots out nature's mark of ſeparation, cancels her kind intention, deſtroys all mental individuality; the letter'd world no longer conſiſts of ſingulars, it is a medly, a maſs; and a hundred books, at bottom, are but one. Why are monkies ſuch maſters of mimickry? why receive they ſuch a talent at imitation? Is it not as the Spartan ſlaves received a licenſe for ebriety, that their betters might be aſhamed of it?

The *third* fault to be found with a ſpirit of *imitation* is, that with great incongruity it makes us poor and proud: makes us think little, and write much; gives us huge folios, which are little better than more reputable cuſhions to promote our repoſe. Have not ſome ſevenfold volumes put us in mind of Ovid's ſevenfold channels of the Nile at the conflagration?

Oſtia ſeptem
Pulverulenta vacant ſeptem ſine flumine valles.

Such leaden labours are like Lycurgus's iron money, which was ſo much leſs in value than in bulk, that it required barns for ſtrong boxes, and a yoke of oxen to draw five hundred pounds.

But notwithſtanding theſe diſadvantages of *imitation*, imitation muſt be the lot (and often an honourable lot it is) of moſt writers. If there is a famine of *invention* in the land, like Joſeph's brethren, we muſt travel far for food; we muſt viſit the remote and rich ancients: but an inventive genius may ſafely ſtay at home; that, like the widow's cruſe, is divinely repleniſhed from within, and affords us a miraculous delight. Whether our own genius be ſuch or not, we diligently ſhould inquire, that we may not go a-begging with gold in our purſe. For there is a mine in man, which muſt be deeply dug ere we can conjecture its contents. Another often ſees that in us, which we ſee not ourſelves; and may there not be that in us which is unſeen by both? That there may, chance often diſcovers, either by a luckily choſen theme, or a mighty premium, or an abſolute neceſſity of exertion, or a noble ſtroke of emulation from another's glory; as that on Thucydides from hearing Herodotus repeat part of his hiſtory at the Olympic games. Had there been no Herodotus, there might have been no Thucydides, and the

world's admiration might have begun at Livy for excellence in that province of the pen. Demoſthenes had the ſame ſtimulation on hearing Calliſtratus; or Tully might have been the firſt of conſummate renown at the bar

Quite clear of the diſpute concerning ancient and modern learning, we ſpeak not of performance, but powers. The modern powers are equal to thoſe before them; modern performance in general is deplorably ſhort. How great are the names juſt mentioned? Yet who will daily affirm, that as great may not riſe up in ſome future, or even in the preſent age? Reaſons there are why talents may not *appear*, none why they may not *exiſt*, as much in one period as another. An evocation of vegetable fruits depends on rain, air, and ſun; an evocation of the fruits of genius no leſs depends on externals. What a marvellous crop bore it in Greece and Rome? And what a marvellous ſunſhine did it there enjoy? What encouragement from the nature of their governments, and the ſpirit of their people? Virgil and Horace owed their divine talents to Heaven; their immortal works to men; thank Mæcenas and Auguſtus for them. Had it not been for theſe, the genius of thoſe poets had lain buried in their aſhes. Athens expended on her theatre, painting, ſculpture, and architecture, a tax levied for the ſupport of a war. Cæſar dropt his papers when Tully ſpoke; and Philip trembled at the voice of Demoſthenes. And has there ariſen but one Tully, one Demoſthenes, in ſo long a courſe of years? The powerful eloquence of them both in one ſtream, ſhould never bear us down into the melancholy perſuaſion, that ſeveral have not been born, though they have not emerged. The ſun as much exiſts in a cloudy day, as in a clear; it is outward, accidental circumſtances that with regard to genius either in nation, or age,

Collectas fugat nubes, ſolemque reducit. Virg.

As great, perhaps greater than thoſe mentioned (preſumptuous as it may ſound) may, poſſibly, ariſe; for, who hath fathomed the mind of man? Its bounds are as unknown, as thoſe of the creation; ſince the birth of which, perhaps, not one has ſo far exerted, as not to leave his poſſibilities beyond his attainments, his powers beyond his exploits. Forming our judgments altogether by what *has* been done, without knowing, or at all inquiring, what poſſibly *might* have been done, we naturally enough fall into too mean an opinion of the human mind. If a ſketch of the divine Iliad before Homer wrote, had been given to mankind, by ſome ſuperior being, or otherwiſe, its execution would probably have appeared beyond the power of man. Now, to ſurpaſs it, we think impoſſible. As the firſt of theſe opinions would evidently have been a miſtake, why may not the ſecond be ſo too? Both are founded on the ſame bottom; on our ignorance of the poſſible dimenſions of the mind of man.

Nor are we only ignorant of the dimenſions of the human mind in general, but even of our own. That a man may be ſcarce leſs ignorant of his own powers, than an oyſter of its pearl, or a rock of its diamond; that he may poſſeſs dormant, unſuſpected abilities, till awakened by loud calls, or ſtung up by ſtriking emergencies; is evident from the ſudden eruption of ſome men out of perfect obſcurity, into public admiration, on the ſtrong impulſe of ſome animating occaſion; not more to the world's great ſurpriſe, than their own. Few authors of diſtinction but have experienced ſomething of this nature, at the firſt beamings of their yet unſuſpected genius on their hitherto dark compoſition. The writer ſtarts at it, as at a lucid meteor in the night; is much ſurpriſed; can ſcarce believe it true. During this happy confuſion, it may be ſaid to him, as to Eve at the lake,

What there thou ſeeſt, fair creature, is thyſelf.
Milton.

Genius, in this view, is like a dear friend in our company under diſguiſe; who, while we are lamenting his abſence, drops his maſk, ſtriking us at once with equal ſurpriſe and joy. This ſenſation, which we ſpeak of in a writer, might favour, and ſo promote, the fable of poetic inſpiration. A poet of a ſtrong imagination, and ſtronger vanity, on feeling it, might naturally enough realiſe the world's mere compliment, and think himſelf truly inſpired. Which is not improbable; for enthuſiaſm of all kinds do no leſs.

Since it is plain, that men may be ſtrangers to their own abilities; and by thinking meanly of them without juſt cauſe, may poſſibly loſe a name, perhaps a name immortal; we would find ſome means to prevent theſe evils. Whatever promotes virtue, promotes ſomething more, and carries its good influence beyond the *moral* man: to prevent theſe evils we borrow two golden rules from *ethics*, which are no leſs golden in *compoſition*, than in life. 1. *Know thyſelf*; 2. *Reverence thyſelf*.

1ſt, *Know thyſelf*. Of ourſelves it may be ſaid, as Martial ſays of a bad neighbour,

Nil tam prope, proculque nobis.

Therefore dive deep into thy boſom; learn the depth, extent, bias, and full ſort of thy mind; contract full intimacy with the ſtranger within thee; excite and cheriſh every ſpark of intellectual light and heat, however ſmothered under former negligence, or ſcattered through the dull, dark maſs of common thoughts; and collecting them into a body, let thy genius riſe (if a genius thou haſt) as the ſun from chaos; and if we ſhould then ſay, like an Indian, *Worſhip it*, (though too bold) yet ſhould we ſay little more than the ſecond rule enjoins, viz. *Reverence thyſelf.*

That is, let not great examples, or authorities, browbeat thy reaſon into too great a diffidence of thyſelf: thyſelf ſo reverence, as to prefer the native growth of thy own mind to the richeſt import from abroad; ſuch borrowed riches make us poor. The man who thus reverences himſelf, will ſoon find the world's reverence to follow his own. His works will ſtand diſtinguiſhed; his the ſole property of them; which property alone can confer the noble title of an *author*; that is, of one who, to ſpeak accurately, *thinks*, and *compoſes*; while other invaders of the preſs. how voluminous, and learned ſoever, with due reſpect be it ſpoken, only *read* and *write*.

This is the difference between thoſe two luminaries in literature, the well-accompliſhed ſcholar, and the divinely-inſpired enthuſiaſt; the firſt is, as the bright morning ſtar; the ſecond, as the riſing ſun. The writer who neglects thoſe two rules above will never ſtand alone; he

makes one of a group, and thinks in wretched unanimity with the throng. Incumbered with the notions of others, and impoverifhed by their abundance, he conceives not the leaft embryo of new thought; opens not the leaft vifta through the gloom of ordinary writers, into the bright walks of rare imagination, and fingular defign; while the true genius is croffing all public roads into frefh untrodden ground, he, up to the knees in antiquity, is treading the facred footfteps of great examples, with the blind veneration of a bigot faluting the papal toe; comfortably hoping full abfolution for the fins of his own underftanding, from the powerful charm of touching his idol's infallibility.

Such meannefs of mind, fuch proftration of our own powers, proceeds from too great admiration of others. Admiration has generally a degree of two very bad ingredients in it; of ignorance, and of fear; and does mifchief in compofition, and in life. Proud as the world is, there is more fuperiority in it given, than affumed: and its grandees of all kinds owe more of their elevation to the littlenefs of others minds, than to the greatnefs of their own. Were not proftrate fpirits their voluntary pedeftals, the figure they make among mankind would not ftand fo high. *Imitators* and *tranflators* are fomewhat of the pedeftal-kind, and fometimes rather raife their *original*'s reputation, by fhowing him to be by them inimitable, than their own. Homer has been tranflated into moft languages; Ælian tells us, that the Indians, (hopeful tutors!) have taught him to fpeak their tongue. What expect we from them? Not Homer's Achilles, but fomething, which, like Patroclus, affumes his name, and, at its peril, appears in his ftead; nor expect we Homer's Ulyffes glorioufly burfting out of his cloud into royal grandeur, but an Ulyffes under difguife, and a beggar to the laft. Such is that inimitable father of poetry, and oracle of all the wife, whom Lycurgus tranfcribed; and for an annual public recital of whofe works Solon enacted a law; that it is much to be feared, that his fo numerous tranflations are but as the publifhed teftimonials of fo many nations, and ages, that this author fo divine is untranflated ftill.

But here,

Cynthius aurem
Vellit,——— VIRG.

and demands juftice for his favourite, and ours. Great things he has done; but he might have done greater. What a fall is it from Homer's numbers, free as air, lofty and harmonious as the fpheres, into childifh fhackles, and tinkling founds! But, in his fall, he is ftill great;——

Nor appears
Lefs than archangel ruin'd, and the excefs
Of glory obfcur'd.—— MILT.

Had Milton never wrote, Pope had been lefs to blame: but when in Milton's genius, Homer, as it were, perfonally rofe to forbid Britons doing him that ignoble wrong; it is lefs pardonable, by that *effeminate* decoration, to put Achilles in petticoats a fecond time. How much nobler had it been, if his numbers had rolled on in full flow, through the various modulations of mafculine melody, into thofe grandeurs of folemn found, which are indifpenfibly demanded by the native dignity of heroic fong? How much nobler, if he had refifted the temptation of that Gothic dæmon, which modern poefy tafting, became mortal? O how unlike the deathlefs, divine harmony of three great names (how juftly joined!) of *Milton*, *Greece*, and *Rome?* His verfe, but for his little fpeck of mortality, in its extreme parts, as his hero had in his heel; like him, had been invulnerable, and immortal. But, unfortunately, *that* was undipt in Helicon; as *this* in Styx. Harmony as well as eloquence is effential to poefy; and a murder of his mufic is putting half Homer to death. *Blank* is a term of diminution; what we mean by blank verfe is, verfe unfallen, uncurft; verfe reclaimed, reinthroned in the true *language of the gods*; who never thundered, nor fuffered their Homer to thunder in rhime.

But fuppofing Pope's Iliad to have been perfect in its kind; yet it is a *tranflation* ftill; which differs as much from an *original*, as the moon from the fun.

But as nothing is more eafy than to write originally wrong; originals are not here recommended, but under the ftrong guard of the firft rule,—*Know thyfelf.* Lucian, who was an original, neglected not this rule, if we may judge by his reply to one who took fome freedom with him. He was at firft an apprentice to a ftatuary; and when he was reflected on as fuch, by being called *Prometheus*, he replied, "I am indeed the inventor of a new work, the model of which I owe to none; and, if I do not execute it well, I deferve to be torn by twelve vultures, inftead of one."

Bacon fays, "Men feek not to know their own ftock, and abilities; but fancy their poffeffions to be greater, and their abilities lefs, than they really are." Which is in effect faying, "That we ought to exert more than we do; and that, on exertion, our probability of fuccefs is greater than we conceive."

Nor have we Bacon's opinion only, but his affiftance too, in favour of originals. His mighty mind travelled round the intellectual world; and, with a more than eagle's eye, faw, and has pointed out, blank fpaces, or dark fpots in it, on which the human mind never fhone: fome of thefe have been enlightened fince; fome are benighted ftill.

Moreover, fo boundlefs are the bold excurfions of the human mind, that in the vaft void beyond real exiftence, it can call forth fhadowy beings, and unknown worlds, as numerous, as bright, and perhaps as lafting as the ftars; fuch quite-original beauties we may call paradifaical,

Natos fine femine flores. OVID.

When fuch an ample area for renowned adventure in *original* attempts lies before us, fhall we be as mere leaden pipes, conveying to the prefent age fmall ftreams of excellence from its grand refervoir in antiquity; and thofe too perhaps mudded in the pafs? Originals fhine like comets; have no peer in their path; are rivalled by none, and the gaze of all: all other compofitions (if they fhine at all) fhine in clufters; like the ftars in the galaxy; where, like bad neighbours, all fuffer from all; each particular being diminifhed, and almoft loft in the throng.

If thoughts of this nature prevailed; if ancients and moderns were no longer confidered as mafters and pupils, but

but as hard-matched rivals for renown; then moderns, by the longevity of their labours, might one day become ancients themselves: and old time, that best weigher of merits, to keep his balance even, might have the golden weight of an Augustan age in both his scales: or rather, our scale might descend: and that of antiquity (as a modern match for it strongly speaks) might *kick the beam*.

Why condemned Maro his admirable epic to the flames? Was it not because his discerning eye saw some length of perfection beyond it? And what he saw, may not others reach? And who bid fairer than our countrymen for that glory? Something new may be expected from Britons particularly; who seem not to be more severed from the rest of mankind by the surrounding sea, than by the current in their veins; and of whom little more appears to be required, in order to give us originals, than a consistency of character, and making their compositions of a piece with their lives. May our genius shine; and proclaim us in that noble view!

—minimâ contentos nocte Britannos. VIRG.

And so it does; for in polite composition, in natural and mathematical knowledge, we have great originals already: Bacon, Boyle, Newton, Shakespeare, Milton, have showed us, that all the winds cannot blow the British flag farther, than an original spirit can convey the British fame; their names go round the world; and what foreign genius strikes not as they pass? Why should not their posterity embark in the same bold bottom of new enterprise, and hope the same success? Hope it they may; or we must assert, either that those originals, which we already enjoy, were written by angels, or deny that we are men. As Simonides said to Pausanias, reason should say to the writer, "Remember thou art a man." And for man not to grasp at all which is laudable within his reach, is a dishonour to human nature, and a disobedience to the divine; for as Heaven does nothing in vain, its gift of talents implies an injunction of their use.

Johnson, in the serious drama, is as much an imitator as Shakespeare is an original. He was very learned, as Sampson was very strong, to his own hurt. Blind to the nature of tragedy, he pulled down all antiquity on his head, and buried himself under it; we see nothing of Johnson, nor indeed of his admired (but also murdered) ancients; for what shone in the historian is a cloud on the poet; and Catiline might have been a good play if Sallust had never written.

Dryden, destitute of Shakespeare's genius, had almost as much learning as Johnson, and, for the buskin, quite as little taste. He was a stranger to the pathos, and, by numbers, expression, sentiment, and every other dramatic cheat, strove to make amends for it; as if a saint could make amends for the want of conscience; a soldier, for the want of valour; or a vestal, of modesty. The noble nature of tragedy disclaims an equivalent; like virtue, it demands the heart; and Dryden had none to give. Let epic poets *think*, the tragedian's point is rather to *feel*; such distant things are a tragedian and a poet, that the latter indulged, destroys the former. Look on Barnwell, and Essex, and see how as to these distant characters Dryden excels, and is excelled. But the strongest demonstration of his no-taste for the buskin, are his tragedies fringed with rhyme; which, in epic poetry, is a sore disease; in the tragic, absolute death. To Dryden's enormity, Pope's was a light offence. As lacemen are foes to mourning, these two authors, rich in rhyme, were no great friends to those solemn ornaments, which the noble nature of their works required.

Must rhyme then, it may be said, be banished? It is to be wished the nature of our language could bear its entire expulsion; but our lesser poetry stands in need of a toleration for it; it raises that, but sinks the great; as spangles adorn children, but expose men.

Among the brightest of the moderns, Mr Addison must take his place. Who does not approach his character with great respect? They who refuse to close with the public in his praise, refuse at their peril. But, if men will be fond of their own opinions, some hazard must be run. He had, what Dryden and Johnson wanted, a warm, and feeling heart; but, being of a grave and bashful nature, through a philosophic reserve, and a sort of moral prudery, he concealed it, where he should have let loose all his fire, and have showed the most tender sensibility of heart. At his celebrated Cato, few tears are shed, but Cato's own; which indeed are truly great, but unaffecting, except to the noble few who love their country better than themselves. The bulk of mankind want virtue enough to be touched by them. His strength of genius has reared up one glorious image, more lofty, and truly golden, than that in the plain of Dura, for cool admiration to gaze at, and warm patriotism (how rare!) to worship; while those two throbbing pulses of the drama, by which alone it is shown to live, *terror* and *pity*, neglected through the whole, leave our unmolested hearts at perfect peace. Thus the poet, like his hero, through mistaken excellence, and virtue overstrained, becomes a sort of suicide; and that which is most dramatic in the drama, dies. All his charms of poetry are but as funeral flowers which adorn, all his noble sentiments but as rich spices which embalm, the tragedy deceased.

Socrates frequented the plays of Euripides; and, what living Socrates would decline the theatre, at the representation of Cato? Tully's assassins found him in his litter, reading the Medea of the Grecian poet, to prepare himself for death. Part of Cato might be read to the same end. In the weight and dignity of moral reflection, Addison resembles that poet, who was called the dramatic philosopher; and is himself, as he says of Cato, *ambitiously sententious*. But as to the singular talent so remarkable in Euripides, at melting down hearts into the tender streams of grief and pity, there the resemblance fails. His beauties sparkle, but do not warm; they sparkle as stars in a frosty night. There is, indeed, a constellation in his play; there is the philosopher, patriot, orator, and poet; but where is the tragedian? And, if that is wanting,

Cur in theatrum Cato severe venisti? MART.

2. *Of epic and dramatic Compositions.*

Tragedy and the epic poem differ little in substantials: in

in both the ſame ends are propoſed, *viz.* inſtruction and amuſement; and in both the ſame means are employed, *viz.* imitation of human actions. They differ in the manner only of imitating: epic poetry deals in narration; tragedy repreſents its facts as paſſing in our ſight: in the former, the poet introduces himſelf as an hiſtorian; in the latter, he preſents his actors, and never himſelf.

This difference, regarding form only, may be thought ſlight: but the effects it occaſions, are by no means ſo; for what we ſee, makes a ſtronger impreſſion than what we learn from others. A narrative poem is a ſtory told by another: facts and incidents paſſing upon the ſtage, come under our own obſervation; and are beſide much enlivened by action and geſture, expreſſive of many ſentiments beyond the reach of language.

A dramatic compoſition has another property, independent altogether of action; which is, that it makes a deeper impreſſion than narration; in the former, perſons expreſs their own ſentiments; in the latter, ſentiments are related at ſecond hand. For that reaſon, Ariſtotle, the father of critics, lays it down as a rule, That in an epic poem the author ought to take every opportunity to introduce his actors, and to confine the narrative part within the narroweſt bounds. Homer underſtood perfectly the advantage of this method; and his poems are both of them in a great meaſure dramatic. Lucan runs to the oppoſite extreme; and is guilty of a ſtill greater fault, in ſtuffing his *Pharſalia* with cold and languid reflections, the merit of which he aſſumes to himſelf, and deigns not to ſhare with his perſonages.

Ariſtotle, from the nature of the fable, divides tragedy into ſimple and complex: but it is of greater moment, with reſpect to dramatic as well as epic poetry, to found a diſtinction upon the different ends attained by ſuch compoſitions. A poem, whether dramatic or epic, that has nothing in view but to move the paſſions, and to exhibit pictures of virtue and vice, may be diſtinguiſhed by the name of *pathetic:* but where a ſtory is purpoſely contrived to illuſtrate ſome moral truth, by ſhowing that diſorderly paſſions naturally lead to external misfortunes, ſuch compoſition may be denominated *moral.* Beſides making a deeper impreſſion than can be done by any moral diſcourſe, it affords conviction equal to that of the moſt accurate reaſoning. To be ſatisfied of this, we need but reflect, that the natural connection which vice hath with miſery, and virtue with happineſs, may be illuſtrated by ſtating a fact as well as by urging an argument. Let us aſſume, for example, the following moral truths: That diſcord among the chiefs renders ineffectual all common meaſures; and that the conſequences of a ſlightly-founded quarrel, foſtered by pride and arrogance, are not leſs fatal than thoſe of the groſſeſt injury: theſe truths may be inculcated, by the quarrel between Agamemnon and Achilles at the ſiege of Troy. In this view, probable circumſtances muſt be invented, ſuch as furniſh an opportunity for the turbulent paſſions to exert themſelves in action: at the ſame time, no accidental nor unaccountable event ought to be admitted; for the neceſſary or probable connection between vice and miſery, is not learned from any events but what are naturally occaſioned by the characters and paſſions of the perſons repreſented, acting in ſuch and ſuch circumſtances. A real event of which we ſee not the cauſe, may be a leſſon to us; becauſe what hath happened may again happen: but this cannot be inferred from a ſtory that is known to be a fiction.

Many are the good effects of ſuch compoſitions. A pathetic compoſition, whether epic or dramatic, tends to a habit of virtue, by exciting us to do what is right, and reſtraining from what is wrong. Its frequent pictures of human woes produce, beſide, two effects extremely ſalutary: they improve our ſympathy, and at the ſame time fortify us in bearing our own misfortunes. A moral compoſition muſt obviouſly produce the ſame good effects, becauſe by being moral it doth not ceaſe to be pathetic: it enjoys beſide an excellence peculiar to itſelf; for it not only improves the heart, as above mentioned, but inſtructs the head by the moral it contains. For our part, we cannot imagine any entertainment more ſuited to a rational being, than a work thus happily illuſtrating ſome moral truth; where a number of perſons of different characters are engaged in an important action, ſome retarding, others promoting, the great cataſtrophe; and where there is dignity of ſtyle as well as of matter. A work of this kind has our ſympathy at command, and can put in motion the whole train of the ſocial affections: our curioſity is by turns excited and gratified; and our delight is conſummated at the cloſe, upon finding, from the characters and ſituations exhibited at the commencement, that every incident down to the final cataſtrophe is natural, and that the whole in conjunction make a regular chain of cauſes and effects.

Conſidering that an epic and a dramatic poem are the ſame in ſubſtance, and have the ſame aim or end, one would readily imagine, that ſubjects proper for the one muſt be equally proper for the other. But conſidering their difference as to form, there will be found reaſon to correct that conjecture, at leaſt in ſome degree. Many ſubjects may indeed be treated with equal advantage in either form; but the ſubjects are ſtill more numerous for which they are not equally qualified; and there are ſubjects proper for the one and not at all for the other. To give ſome ſlight notion of the difference, as there is no room here for enlarging upon every article, we obſerve, that dialogue is the beſt qualified for expreſſing ſetiments, and narrative for diſplaying facts. Heroiſm, magnanimity, undaunted courage, and the whole tribe of the elevated virtues, figure beſt in action: tender paſſions, and the whole tribe of ſympathetic affections, figure beſt in ſentiment: what we feel is the moſt remarkable in the latter; what we perform is the moſt remarkable in the former. It clearly follows, that tender paſſions are more peculiarly the province of tragedy, grand and heroic actions of epic poetry.

The ſubject beſt fitted for tragedy is a ſtory where a man has himſelf been the cauſe of his misfortune. But this man muſt neither be deeply guilty, nor altogether innocent: the misfortune muſt be occaſioned by a fault incident to human nature, and therefore venial. Misfortunes of this kind call forth the ſocial affections, and warmly intereſt the ſpectator. An accidental misfortune, if not extremely ſingular, doth not greatly move

our

our pity: the perſon who ſuffers, being innocent, is freed from the greateſt of all torments, that anguiſh of mind which is occaſioned by remorſe.

An atrocious criminal, on the other hand, who brings misfortunes upon himſelf, excites little pity, for a different reaſon: his remorſe, it is true, aggravates his diſtreſs, and ſwells the firſt emotions of pity; but then our hatred of him as a criminal blending with pity, blunts its edge conſiderably. Misfortunes that are not innocent, nor highly criminal, partake the advantages of each extreme: they are attended with remorſe to embitter the diſtreſs, which raiſes our pity to a great height; and the ſlight indignation we have at a venial fault, detracts not ſenſibly from our pity. For this reaſon, the happieſt of all ſubjects for raiſing pity, is where a man of integrity falls into a great misfortune by doing an action that is innocent, but which by ſome ſingular means he conceives to be criminal: his remorſe aggravates his diſtreſs; and our compaſſion, unreſtrained by indignation, riſes to its higheſt pitch. Pity comes thus to be the ruling paſſion of a pathetic tragedy; and by proper repreſentation, may be raiſed to a height ſcarce exceeded by any thing felt in real life. A moral tragedy takes in a larger field; for, beſide exerciſing our pity, it raiſes another paſſion, ſelfiſh indeed, but which deſerves to be cheriſhed equally with the ſocial affections. The paſſion we have in view is fear or terror; for when a misfortune is the natural conſequence of ſome wrong bias in the temper, every ſpectator who is conſcious of ſuch a wrong bias in his own temper, takes the alarm, and dreads his falling into the ſame misfortune: and it is by this emotion of fear or terror, frequently reiterated in a variety of moral tragedies, that the ſpectators are put upon their guard againſt the diſorders of paſſion.

The commentators upon Ariſtotle, and other critics, have been much gravelled about the account given of tragedy by this author: "That by means of pity and terror, it refines or purifies in us all ſorts of paſſion." But no one who has a clear conception of the end and effects of a good tragedy, can have any difficulty about Ariſtotle's meaning: our pity is engaged for the perſons repreſented; and our terror is upon our own account. Pity indeed is here made to ſtand for all the ſympathetic emotions, becauſe of theſe it is the capital. There can be no doubt, that our ſympathetic emotions are refined or improved by daily exerciſe; and in what manner our other paſſions are refined by terror, we have juſt now ſaid.

With reſpect to ſubjects of this kind, it may indeed be a doubtful queſtion, whether the concluſion ought not always to be fortunate. Where a perſon of integrity is repreſented as ſuffering to the end under misfortunes purely accidental, we depart diſcontented, and with ſome obſcure ſenſe of injuſtice: for ſeldom is man ſo ſubmiſſive to providence, as not to revolt againſt the tyranny and vexations of blind chance; he will be inclined to ſay, This ought not to be. We give for an example the Romeo and Juliet of Shakeſpeare, where the fatal cataſtrophe occaſioned by Friar Laurence's coming to the monument a minute too late. We are vexed at the unlucky chance, and go away diſſatisfied. Such impreſſions, which ought not to be cheriſhed, are a ſufficient reaſon for excluding ſtories of that kind from the theatre. The misfortunes of a virtuous perſon, ariſing from neceſſary cauſes, or from a chain of unavoidable circumſtances, will be conſidered in a different light: chance affords always a gloomy proſpect, and in every inſtance gives an impreſſion of anarchy and miſrule: a regular chain, on the contrary, of cauſes and effects, directed by the general laws of nature, never fails to ſuggeſt the hand of Providence; to which we ſubmit without reſentment, being conſcious that ſubmiſſion is our duty. For that reaſon, we are not diſguſted with the diſtreſſes of Voltaire's Mariamne, though redoubled on her till the moment of her death, without the leaſt fault or failing on her part: her misfortunes are owing to a cauſe extremely natural, and not unfrequent, the jealouſy of a barbarous huſband. The fate of Deſdemona in the Moor of Venice, affects us in the ſame manner. We are not ſo eaſily reconciled to the fate of Cordelia in King Lear: the cauſes of her misfortune are by no means ſo evident, as to exclude the gloomy notion of chance. In ſhort, a perfect character ſuffering under misfortunes, is qualified for being the ſubject of a pathetic tragedy, provided chance be excluded. Nor is a perfect character altogether inconſiſtent with a moral tragedy: it may ſucceſsfully be introduced as an under-part, ſuppoſing the chief place to be filled with an imperfect character from which a moral can be drawn. This is the caſe of Deſdemona and Mariamne juſt now mentioned; and it is the caſe of Monimia and Belvidera, in Otway's two tragedies, the Orphan, and Venice Preſerved.

Fable operates on our paſſions, by repreſenting its events as paſſing in our ſight, and by deluding us into a conviction of reality. Hence, in epic and dramatic compoſitions, it is of importance to employ means of every ſort that may promote the deluſion, ſuch as the borrowing from hiſtory ſome noted event, with the addition of circumſtances that may anſwer the author's purpoſe: the principal facts are known to be true; and we are diſpoſed to extend our belief to every circumſtance. But in chuſing a ſubject that makes a figure in hiſtory, greater precaution is neceſſary than where the whole is a fiction. In the latter caſe there is full ſcope for invention: the author is under no reſtraint other than that the characters and incidents be juſt copies of nature. But where the ſtory is founded on truth, no circumſtances muſt be added, but ſuch as connect naturally with what are known to be true; hiſtory may be ſupplied, but muſt not be contradicted: further, the ſubject choſen muſt be diſtant in time, or at leaſt in place; for the familiarity of perſons and events nearly connected with us, ought by all means to be avoided. Familiarity ought more eſpecially to be avoided in an epic poem, the peculiar character of which is dignity and elevation: modern manners make but a poor figure in ſuch a poem.

After Voltaire, no writer, it is probable, will think of rearing an epic poem upon a recent event in the hiſtory of his own country. But an event of this kind is perhaps not altogether unqualified for tragedy: it was admitted in Greece; and Shakeſpear has employed it ſucceſsfully

cessfully in several of his pieces. One advantage it possesses above fiction, that of more readily engaging our belief, which tends above any other particular to raise our sympathy. The scene of comedy is generally laid at home: familiarity is no objection; and we are peculiarly sensible of the ridicule of our own manners.

After a proper subject is chosen, the dividing it into parts requires some art. The conclusion of a book in an epic poem, or of an act in a play, cannot be altogether arbitrary; nor be intended for so slight a purpose as to make the parts of equal length. The supposed pause at the end of every book, and the real pause at the end of every act, ought always to coincide with some pause in the action. In this respect, a dramatic or epic poem ought to resemble a sentence or period in language, divided into members that are distinguished from each other by proper pauses; or it ought to resemble a piece of music, having a full close at the end, preceded by imperfect closes that contribute to the melody. Every act in a dramatic poem ought therefore to close with some incident that makes a pause in the action; for otherwise there can be no pretext for interrupting the representation: it would be absurd to break off in the very heat of action; against which every one would exclaim: the absurdity still remains, though the action relents, if it be not actually suspended for some time. This rule is also applicable to an epic poem: though there, a deviation from the rule is less remarkable; because it is in the reader's power to hide the absurdity, by proceeding instantly to another book. The first book of the Paradise Lost ends without any regular close, perfect or imperfect: it breaks off abruptly, where Satan, seated on his throne, is prepared to make a speech to the convocated host of the fallen angels; and the second book begins with the speech. Milton seems to have copied the Æneid, of which the two first books are divided much in the same manner. Neither is there any proper pause at the end of the fifth book of the Æneid. There is no proper pause at the end of the seventh book of Paradise Lost, nor at the end of the eleventh.

This branch of the subject shall be closed with a general rule, That action being the fundamental part of every composition whether epic or dramatic, the sentiments and tone of language ought to be subservient to the action, so as in every respect to appear natural, and proper for the occasion. The application of this rule to our modern plays, would reduce the bulk of them to a skeleton.

After carrying on together epic and dramatic compositions, we proceed to handle them separately, and to mention circumstances peculiar to each, beginning with the epic kind. In a theatrical entertainment, which employs both the eye and the ear, it would be a gross absurdity to introduce upon the stage superior beings in a visible shape. There is not place for this objection in an epic poem; and Boileau, with many other critics, declares strongly for this sort of machinery in an epic poem. But waving authority, which is apt to impose upon the judgment, let us draw what light we can from reason. This matter is but indistinctly handled by critics: the poetical privilege of animating insensible objects for enlivening a description, is very different from what is termed *machinery*, where deities, angels, devils, or other supernatural powers, are introduced as real personages, mixing in the action, and contributing to the catastrophe; and yet these two things are constantly jumbled together in the reasoning. The former is founded on a natural principle: but can the latter claim the same authority? so far from it, that nothing can be more unnatural. Its effects, at the same time, are deplorable. First, it gives an air of fiction to the whole; and prevents that impression of reality which is requisite to interest our affections, and to move our passions: this of itself is sufficient to explode machinery, whatever entertainment it may afford to readers of a fantastic taste or irregular imagination. And, next, were it possible, by disguising the fiction, to delude us into a notion of reality, an insuperable objection would still remain, which is, that the aim or end of an epic poem can never be attained in any perfection where machinery is introduced; for an evident reason, that virtuous emotions cannot be raised successfully but by the actions of those who are endued with passions and affections like our own, that is, by human actions: and as for moral instruction, it is clear, that none can be drawn from beings who act not upon the same principles with us. A fable in Æsop's manner is no objection to this reasoning: his lions, bulls, and goats, are truly men under disguise: they act and feel in every respect as human beings; and the moral we draw is founded on that supposition. Homer, it is true, introduces the gods into his fable: but he was authorised to take that liberty by the religion of his country; it being an article in the Grecian creed, that the gods often interpose visibly and bodily in human affairs. We must however observe, that Homer's deities do no honour to his poems: fictions that transgress the bounds of nature, seldom have a good effect: they may inflame the imagination for a moment, but will not be relished by any person of a correct taste. Let us add, that of whatever use such fictions may be to a mean genius, an able writer has much finer materials of Nature's production, for elevating his subject, and making it interesting.

The marvellous is indeed so much promoted by machinery, that it is not wonderful to find it embraced by the bulk of writers, and perhaps of readers. If indulged at all, it is generally indulged to excess. Homer introduces his deities with no greater ceremony than his mortals; and Virgil has still less moderation: a pilot spent with watching cannot fall asleep and drop into the sea by natural means: one bed cannot hold the two lovers, Æneas and Dido, without the immediate interposition of superior powers. The ridiculous in such fictions must appear, even through the thickest vail of gravity and solemnity.

Angels and devils serve equally with the Heathen deities, as materials for figurative language, perhaps better among Christians, because we believe in them, and not in the Heathen deities. But every one is sensible, as well as Boileau, that the invisible powers in our creed make a much worse figure as actors in a modern poem, than the invisible powers in the Heathen creed did in ancient times. The reason seems to be what follows. The Heathen deities, in the opinion of their votaries, were

were beings elevated one ſtep only above mankind, actuated by the ſame paſſions, and directed by the ſame motives; therefore not altogether improper to mix with men in an important action. In our creed, ſuperior beings are placed at ſuch a mighty diſtance from us, and are of a nature ſo different, that with no propriety can they appear with us upon the ſame ſtage: man is a creature ſo much inferior, that he loſes all dignity when ſet in oppoſition.

There can be no doubt, that an hiſtorical poem admits the embelliſhment of allegory, as well as of metaphor, ſimile, or other figure. Moral truth, in particular, is finely illuſtrated in the allegorical manner: it amuſes the fancy to find abſtract terms, by a ſort of magic, converted into active beings; and it is delightful to trace a general propoſition in a pictured event. But allegorical beings ſhould be confined within their own ſphere, and never be admitted to mix in the principal action, nor to co-operate in retarding or advancing the cataſtrophe; which would have a ſtill worſe effect than inviſible powers, and we are ready to aſſign the reaſon. The impreſſion of real exiſtence, eſſential to an epic poem, is inconſiſtent with that figurative exiſtence which is eſſential to an allegory; and therefore no method can be more effectual to prevent the impreſſion of reality, than to introduce allegorical beings co-operating with thoſe whom we conceive to be really exiſting. The love-epiſode in the Henriade, inſufferable by the diſcordant mixture of allegory with real life, is copied from that of Rinaldo and Armida in the *Gieruſalemme liberata*, which hath no merit to intitle it to be copied. An allegorical object, ſuch as Fame in the Æneid, and the Temple of Love in the Henriade, may find place in a deſcription: but to introduce Diſcord as a real perſonage, imploring the aſſiſtance of Love as another real perſonage, to enervate the courage of the hero, is making theſe figurative beings act beyond ther ſphere, and creating a ſtrange jumble of truth and fiction.

What is the true notion of an epiſode? or how is it to be diſtinguiſhed from the principal action? Every incident that promotes or retards the cataſtrophe, muſt be a part of the principal action. This clears the nature of an epiſode; which may be defined, "An incident connected with the principal action, but contributing neither to advance nor retard it." The deſcent of Æneas into hell doth not advance nor retard the cataſtrophe; and therefore is an epiſode. The ſtory of Niſus and Euryalus, producing an alteration in the affairs of the contending parties, is a part of the principal action. The family-ſcene in the ſixth book of the Iliad is of the ſame nature: by Hector's retiring from the field of battle to viſit his wife, the Grecians had liberty to breathe, and even to preſs upon the Trojans. Such being the nature of an epiſode, the unavoidable effect of it muſt be, to break in upon the unity of action; and therefore it ought never to be indulged, unleſs to unbend the mind after the fatigue of a long narration. This purpoſe of an epiſode demands the following conditions: it ought to be well connected with the principal action: it ought to be lively and intereſting: it ought to be ſhort: and a time ought to be choſen when the principal action relents.

Next, upon the peculiarities of a dramatic poem. And the firſt we ſhall mention is a double plot; one of which muſt be of the nature of an epiſode in an epic poem; for it would diſtract the ſpectator, inſtead of entertaining him, if he were forced to attend, at the ſame time, to two capital plots equally intereſting. And even ſuppoſing it an under-plot, of the nature of an epiſode, it ſeldom hath a good effect in tragedy, of which ſimplicity is a chief property; for an intereſting ſubject that engages our warmeſt affections, occupies our whole attention, and leaves no room for any ſeparate concern. Variety is more tolerable in comedy, which pretends only to amuſe, without totally occupying the mind. But even here to make a double plot agreeable, is no ſlight effort of art: the under plot ought not to vary greatly in its tone from the principal; for diſcordant paſſions are unpleaſant when jumbled together; which, by the way, is an inſuperable objection to tragi-comedy. Upon this account, we blame the Provoked Huſband: all the ſcenes that bring the family of the Wrongheads into action, being ludicrous and farcical, agree very ill with the principal ſcenes, diſplaying ſevere and bitter expoſtulations between lord Townly and his lady. The ſame objection touches not the double plot of the Careleſs Huſband; the different ſubjects being ſweetly connected, and having only ſo much variety as to reſemble ſhades of colours harmoniouſly mixed. But this is not all. The under plot ought to be connected with that which is principal, ſo much at leaſt as to employ the ſame perſons: the under-plot ought to occupy the intervals or pauſes of the principal action; and both ought to be concluded together. This is the caſe of the Merry Wives of Windſor.

Violent action ought never to be repreſented on the ſtage. While the dialogue runs on, a thouſand particulars concur to delude us into an impreſſion of reality, genuine ſentiments, paſſionate language, and perſuaſive geſture: the ſpectator once engaged, is willing to be deceived, loſes ſight of himſelf, and without ſcruple enjoys the ſpectacle as a reality. From this abſent ſtate, he is rouſed by violent action: he wakes as from a pleaſing dream, and gathering his ſenſes about him, finds all to be a fiction.

The French critics join with Horace in excluding from the ſtage the ſhedding blood; but they have overlooked the moſt ſubſtantial objection, that above-mentioned, urging only that it is barbarous, and ſhocking to a polite audience. But the Greeks had no notion of ſuch delicacy, or rather effeminacy; witneſs the murder of Clytemneſtra by her ſon Oreſtes, paſſing behind the ſcene, as repreſented by Sophocles: her voice is heard calling out for mercy, bitter expoſtulations on his part, loud ſhrieks upon her being ſtabbed, and then a deep ſilence. We appeal to every perſon of feeling, whether this ſcene be not more horrible, than if the deed had been committed in ſight of the ſpectators upon a ſudden guſt of paſſion. If Corneille, in repreſenting the affair between Horatius and his ſiſter upon which murder enſues behind the ſcene, had

had no other view but to remove from the ſpectators a ſhocking action, he certainly was in a capital miſtake: for murder in cold blood, which in ſome meaſure was the caſe as repreſented, is more ſhocking to a polite audience, even where the concluſive ſtab is not ſeen, than the ſame act performed in their preſence, when it is occaſioned by violent and unpremeditated paſſion, as ſuddenly repented of as committed. We heartily agree with Addiſon, that no part of this incident ought to have been repreſented, but reſerved for a narrative, with every alleviating circumſtance in favour of the hero. This is the only method to avoid the difficulties that unqualify this incident for repreſentation, a deliberate murder on the one hand, and on the other a violent action performed on the ſtage, which muſt rouſe the ſpectator from his dream of reality.

A few words upon the dialogue, which ought to be ſo conducted as to be a true repreſentation of nature. Every ſingle ſpeech, ſhort or long, ought to ariſe from what is ſaid by the former ſpeaker, and furniſh matter for what comes after, till the end of the ſcene. In this view, the whole ſpeeches, from firſt to laſt, repreſent ſo many links, all connected together in one regular chain. No author, ancient or modern, poſſeſſes the art of dialogue equal to Shakeſpeare. Dryden in this particular may juſtly be placed as his oppoſite: he frequently introduces three or four perſons ſpeaking upon the ſame ſubject, each throwing out his own ſentiments ſeparately, without regarding what is ſaid by the reſt; take for an example the firſt ſcene of Aurenzebe: ſometimes he makes a number club in relating an event, not to a ſtranger, ſuppoſed ignorant of it, but to one another, for the ſake merely of ſpeaking: of which notable ſort of dialogue, we have a ſpecimen in the firſt ſcene of the firſt part of the Conqueſt of Granada. In the ſecond part of the ſame tragedy, ſcene ſecond, the king, Abenamar, and Zulema, make their ſeparate obſervations, like ſo many ſoliloquies, upon the fluctuating temper of the mob: a dialogue ſo uncouth, puts one in mind of two ſhepherds in a paſtoral, excited by a prize to pronounce verſes alternately, each in praiſe of his own miſtreſs.

The bandying ſentiments in this manner, beſide an unnatural air, has another bad effect: it ſtays the courſe of the action, becauſe it is not productive of any conſequence. In Congreve's comedies, the action is often ſuſpended to make way for a play of wit.

No fault is more common among writers, than to prolong a ſpeech after the impatience of the perſon to whom it is addreſſed ought to prompt him or her to break in. Conſider only how the impatient actor is to behave in the mean time. To expreſs his impatience in violent action without interrupting, would be unnatural; and yet to diſſemble his impatience by appearing cool where he ought to be highly inflamed, would be no leſs unnatural.

Rhyme being unnatural and diſguſtful in dialogue, is happily baniſhed from our theatre: the only wonder is, that it ever found admittance, eſpecially among a people accuſtomed to the more manly freedom of Shakeſpeare's dialogue. By baniſhing rhyme, we have gained ſo much as never once to dream that there can be any further improvement. And yet, however ſuitable blank verſe may be to elevated characters and warm paſſions, it muſt appear improper and affected in the mouths of the lower ſort. Why then ſhould it be a rule, that every ſcene in tragedy muſt be in blank verſe? Shakeſpeare, with great judgment, has followed a different rule; which is, to intermix proſe with verſe, and only to employ the latter where the importance or dignity of the ſubject requires it. Familiar thoughts and ordinary facts ought to be expreſſed in plain language; and if it appear not ridiculous to hear a footman deliver a ſimple meſſage in blank verſe, a vail muſt be drawn over the ridiculous appearance by the force of cuſtom. In ſhort, that variety of characters and of ſituations, which is the life of a play, requires not only a ſuitable variety in the ſentiments, but alſo in the diction.

Composition, in painting, conſiſts of two parts, invention and diſpoſition; the firſt whereof is the choice of the objects which are to enter into the compoſition of the ſubject the painter intends to execute, and is either ſimply hiſtorical or allegorical.

Composition, in commerce, a contract between an inſolvent debtor and his creditors, whereby the latter accept of a part of the debt in compenſation for the whole, and give a general acquittance accordingly.

Composition, in printing, commonly termed compoſing, the arranging of ſeveral types, or letters, in the compoſing-ſtick, in order to form a line; and of ſeveral lines ranged in order in the galley, to make a page; and of ſeveral pages, to make a form. See Printing.

COMPOST, in huſbandry and gardening, ſeveral ſorts of ſoils, or earthy matter, mixed together, in order to make a manure, for aſſiſting the natural earth in the work of vegetation, by way of amendment or improvement. See Agriculture.

COMPOSTELLA, the capital of Galicia, in Spain, remarkable for the devotion paid there by pilgrims from all countries to the relics of St James.

COMPOUND, in a general ſenſe, an appellation given to whatever is compoſed, or made up of different things: thus we ſay, a compound word, compound ſound, compound taſte, compound force, *&c.*

Compound-interest. See Interest.

Compound numbers, thoſe which may be divided by ſome other number beſides unity, without leaving any remainder: ſuch are 18, 20, *&c.* the firſt being meaſured by the numbers 2, 6, or 9; and the ſecond by the numbers 2, 4, 5, 10.

COMPREHENSION, in logic, the ſame with apprehenſion.

COMPRESSION, the act of preſſing or ſqueezing ſome matter, ſo as to ſet its parts nearer to each other, and make it poſſeſs leſs ſpace.

COMPRINT, among bookſellers, ſignifies a ſurreptitious printing of another's copy, in order to gain thereby, which is expreſsly contrary to ſtatute 14 Car. II.

COMPROMISE, a treaty, or contract, whereby two contending

contending parties eſtabliſh one or more arbitrators, to judge of and terminate their difference in an amicable way.

COMPUNCTION, in theology, an inward grief of mind, for having offended God.

COMPUTATION, in a general ſenſe, the manner of eſtimating time, weights, meaſure, moneys, or quantities of any kind.

CONARION, or CONOIDES, a name for the pineal gland. See Vol. I. p. 286.

CONATUS, a term frequently uſed in philoſophy and mathematics, defined by ſome to be a quantity of motion, not capable of being expreſſed by any time, or length; as the *conatus recedendi ab axe motus*, is the endeavour which a body, moved circularly, makes to recede, or fly off from the centre or axis of its motion. See MECHANICS.

CONCATENATION, a term chiefly uſed in ſpeaking of the mutual dependence of ſecond cauſes upon each other.

CONCAVE, an appellation uſed in ſpeaking of the inner ſurface of hollow bodies, but more eſpecially of ſpherical ones.

CONCAVE GLASSES, ſuch as are ground hollow, and are uſually of a ſpherical figure, though they may be of any other, as parabolical, *&c.* All objects ſeen through concave glaſſes, appear erect and diminiſhed. See OPTICS.

CONCENTRATION, in general, ſignifies the bringing things nearer a center. Hence the particles of ſalt, in ſea-water, are ſaid to be concentrated; that is, brought nearer each other, by evaporating the watery part. See CHEMISTRY.

CONCENTRIC, in mathematics, ſomething that has the ſame common center with another: it ſtands in oppoſition to excentric.

CONCEPTION, among phyſicians, *&c.* denotes the firſt formation of an embryo in the womb of its parent, who from that time becomes pregnant. See GENERATION.

CONCEPTION, in logic. See APPREHENSION.

CONCEPTION, in geography, a city of Chili, in South America, ſituated on the Pacific Ocean, in 79° W. long. and 37° S. lat.

CONCEPTION is alſo the capital of the province of Veragua, in Mexico, about 100 miles weſt of Porto Bello: W. long. 83°, and N. lat. 10°.

CONCERT, or CONCERTO, in muſic, a number or company of muſicians, playing or ſinging the ſame piece of muſic or ſong at the ſame time. See MUSIC.

CONCERTATO intimates the piece of muſic to be compoſed in ſuch a manner, as that all the parts may have their recitativos, be it for two, three, four, or more voices or inſtruments.

CONCERTO GROSSI, the grand chorus of a concert, or thoſe places where all the ſeveral parts perform or play together.

CONCHA, in zoology, a ſynonime of the MYTILUS, SOLEN, *&c.* See theſe articles.

CONCHA, in anatomy. See Vol. I. p. 297.

CONCHOID, in geometry, the name of a curve, given it by its inventor Nicomedes. See FLUXIONS.

CONCHYLIA, a general name for all kinds of petrified ſhells, as limpets, cochlea, nautili, conchæ, lepades, *&c.*

CONCINNOUS *intervals*, in muſic, are ſuch as are fit for muſic, next to, and in combination with concords; being neither very agreeable, nor diſagreeable in themſelves, but having a good effect, as by their oppoſition they heighten the more eſſential principles of pleaſure; or as by their mixture and combination with them, they produce a variety neceſſary to our being better pleaſed.

CONCINNOUS *ſyſtem*, in muſic. A ſyſtem is ſaid to be concinnous, or divided concinnouſly, when its parts, conſidered as ſimple intervals, are concinnous; and are beſides placed in ſuch an order between the extremes, as that the ſucceſſion of ſounds, from one extreme to the other, may have an agreeable effect.

CONCLAVE, the place in which the cardinals of the Romiſh church meet, and are ſhut up, in order to the election of a pope.

The conclave is a range of ſmall cells, ten feet ſquare, made of wainſcot: theſe are numbered, and drawn for by lot. They ſtand in a line along the galleries and hall of the Vatican, with a ſmall ſpace between each. Every cell has the arms of the cardinal over it. The conclave is not fixed to any one determinate place, for the conſtitutions of the church allow the cardinals to make choice of ſuch a place for the conclave as they think moſt convenient; yet it is generally held in the Vatican.

The conclave is very ſtrictly guarded by troops: neither the cardinals, nor any perſon ſhut up in the conclave, are ſpoke to, but at the hours allowed of, and then in Italian or Latin; even the proviſions for the conclave are examined, that no letters be conveyed by that means from the miniſters of foreign powers, or other perſons who may have an intereſt in the election of the pontiff.

CONCLAVE is alſo uſed for the aſſembly, or meeting, of the cardinals ſhut up, for the election of a pope.

CONCLUSION, in logic, the conſequence or judgment, drawn from what was aſſerted in the premiſſes; or the previous judgments in reaſoning, gained from combining the extreme ideas between themſelves.

CONCOCTION, in medicine, the change which the food undergoes in the ſtomach, *&c.* to become chyle. See CHYLE.

CONCOMITANT, ſomething that accompanies or goes along with another.

CONCORD, in grammar, that part of conſtruction called ſyntax, in which the words of a ſentence agree; that is, in which nouns are put in the ſame gender, number, and caſe; and verbs in the ſame number and perſon with nouns and pronouns.

CONCORD, in muſic, the relation of two ſounds that are always agreeable to the ear, whether applied in ſucceſſion or conſonance. See MUSIC.

CONCORDANCE, a ſort of dictionary of the Bible, explaining

explaining the words thereof in alphabetical order, with the ſeveral books, chapters, and verſes quoted, in which they are contained.

CONCORDIA, in geography, a town of the dutchy of Mantua in Italy, about fifteen miles ſouth-eaſt of the city of Mantua: E. long. 11° 20′, and N. lat. 45°.

CONCRETE, in the ſchool-philoſophy, an aſſemblage or compound.

Concrete, in natural philoſophy and chemiſtry, ſignifies a body made up of different principles, or any mixed body: thus ſoap is a factitious concrete, or a body mixed together by art; and antimony is a natural concrete, or a mixed body, compounded in the bowels of the earth.

CONCRETION, the uniting together ſeveral ſmall particles of a natural body into ſenſible maſſes, or concretes, whereby it becomes ſo and ſo figured and determined, and is endued with ſuch and ſuch properties.

Concretion is alſo the act whereby ſoft bodies are rendered hard; or an inſenſible motion of the particles of a fluid or a ſoft body, whereby they come to a conſiſtence. It is indifferently uſed for induration, condenſation, congelation, and coagulation.

CONCUBINAGE, denotes ſometimes a criminal or prohibited commerce between the ſexes; in which ſenſe it comprehends adultery, inceſt, and ſimple fornication: but, in a more limited ſenſe, it ſignifies the cohabitation of a man and a woman in the way of marriage, without having paſſed the ceremony thereof.

CONCUBINE, a woman whom a man takes to cohabit with in the manner of a wife, without being authoriſed thereto by a legal marriage.

CONCUPISCENCE, according to divines, an irregular appetite, or luſt after carnal things, inherent in the nature of man ever ſince the fall.

CONDAMIN, in botany. See Cinchona.

CONDE, a town of the French Netherlands, in the province of Hainault, ſituated on the river Scheld, about twelve miles weſt of Mons: E. long. 3° 40′, N. lat. 50° 35′.

CONDENSATION, the act whereby a body is rendered more denſe, compact, and heavy.

CONDENSER, a pneumatic engine, or ſyringe, whereby an uncommon quantity of air may be crouded into a given ſpace; ſo that ſometimes ten atmoſpheres, or ten times as much air as there is at the ſame time, in the ſame ſpace, without the engine, may be thrown in by means of it, and its egreſs prevented by valves properly diſpoſed. See Pneumatics.

CONDITION, in the civil law, a clauſe of obligation ſtipulated as an article of a treaty or contract; or in a donation of teſtament, legacy, &c. in which laſt caſe a donee does not loſe his donative, if it be charged with any diſhoneſt or impoſſible conditions.

CONDITIONALS, ſomething not abſolute but ſubject to conditions.

CONDOM, the capital of the Condomois, in the province of Gaſcony, in France, about ſixty miles ſouth-eaſt of Bourdeaux. It is a biſhop's ſee, and ſituated in 20′ E. long. and 44° 5′ N. lat.

CONDORMIENTES, in church hiſtory, religious ſectaries, who hold their name from lying all together, men and women, young and old. They aroſe in the thirteenth century near Cologne, where they are ſaid to have worſhipped an image of Lucifer, and to have received anſwers and oracles from him.

CONDUCTOR, in ſurgery, an inſtrument which ſerves to conduct the knife in the operation of cutting for the ſtone, and in laying up ſinuſes and fiſtulas. See Surgery.

CONDUIT, a canal or pipe for the conveyance of water, or other fluid.

There are ſeveral ſubterraneous conduits through which the waters paſs that form ſprings. Artificial conduits for water are made of lead, ſtone, caſt-iron, potter's earth, timber, &c.

CONDYLOMA, in medicine, a tubercle or callous eminence which ariſes in the folds of the anus, or rather a ſwelling or hardening of the wrinkles of that part.

CONDYLUS, a name given by anatomiſts to a knot in any of the joints, formed by the epiphyſis of a bone.

CONE, in geometry, a ſolid figure, having a circle for its baſe, and its top terminated in a point or vertex. See Conic Sections.

Cone *of rays*, in optics, includes all the ſeveral rays which fall from any radiant point on the ſurface of a glaſs. See Optics.

CONESSI, a ſort of bark of a tree which grows on the Coromandel coaſt in the Eaſt-Indies. It is recommended in a letter to Dr Monro, in the Medical Eſſays, as a ſpecific in diarrhœas. It is to be pounded into a fine powder, and made into an electuary with ſyrup of oranges; and the bark ſhould be freſh, and the electuary new made every day, or ſecond day, otherwiſe it loſes its auſtere but grateful bitterneſs on the palate, and its proper effects on the inteſtines.

CONFECTION, in pharmacy, ſignifies in general any thing prepared with ſugar: in particular, it imports ſomething preſerved, eſpecially dry ſubſtances. It alſo ſignifies a liquid or ſoft electuary, of which there are various ſorts directed in diſpenſatories.

CONFECTS, a denomination given to fruits, flowers, herbs, roots, &c. when boiled or prepared with ſugar or honey, to diſpoſe them to keep, and render them more agreeable to the taſte.

CONFERVA, in botany, a genus of the cryptogamia algæ claſs, conſiſting of oblong, capillary filaments; without any joints. There are twenty-one ſpecies.

CONFESSION, in a legal ſenſe, an acknowledgment of ſome truth, though in prejudice of the perſon that makes the declaration.

Confession, among divines, the verbal acknowledgement which a Chriſtian makes of his ſins.

Among the Jews it was a cuſtom, on the annual feaſt of expiation, for the high-prieſt to make confeſſion of ſins to God in the name of the whole people: beſides this general confeſſion, the Jews were enjoined, if their ſins were a breach of the firſt table of the law, to make confeſſion of them to God; but violations offered the ſecond table, were to be acknowledged to their brethren. The confeſſions of the primitive Chri-

ſtians were all voluntary, and not impoſed on them by any laws of the church; yet private confeſſion was not only allowed, but encouraged.

The Romiſh church requires confeſſion not only as a duty, but has advanced it to the dignity of a ſacrament: this confeſſion is made to the prieſt, and is private and auricular; and the prieſt is not to reveal them under pain of the higheſt puniſhment.

CONFESSION *of faith*, a liſt of the ſeveral articles of belief in any church.

CONFESSIONAL, or CONFESSIONARY, a place in churches, under the great altar, where the bodies of deceaſed ſaints, martyrs, and confeſſors, were depoſited.

CONFESSOR, in the Romiſh church, a prieſt who is impowered to receive the confeſſion of penitents, and to give them abſolution.

CONFIGURATION, the outward figure which bounds bodies, and gives them their external appearance; being that which, in a great meaſure, conſtitutes the ſpecific difference between bodies.

CONFIRMATION *by a ſuperior*. See SCOTS LAW, title, *Tranſmiſſion of rights by confirmation*.

CONFIRMATION *of a teſtament*. See SCOTS LAW, title, *Succeſſion in moveables*.

CONFIRMATION, in theology, the ceremony of laying on of hands, for the conveyance of the Holy Ghoſt.

The antiquity of this ceremony is, by all ancient writers, carried as high as the apoſtles, and founded upon their example and practice. In the primitive church, it uſed to be given to Chriſtians immediately after baptiſm, if the biſhop happened to be preſent at the ſolemnity. Among the Greeks, and throughout the Eaſt, it ſtill accompanies baptiſm: but the Romaniſts make it a diſtinct independent ſacrament. Seven years is the ſtated time for confirmation: however, they are ſometimes confirmed before, and ſometimes after that age. The perſon to be confirmed has a god father and god mother appointed him, as in baptiſm. The order of confirmation in the church of England, does not determine the preciſe age of the perſons to be confirmed.

CONFISCATION, in law, the adjudication of goods or effects to the public treaſury; as the bodies and effects of criminals, traitors, *&c.*

CONFLAGRATION, the general burning of a city, or other conſiderable place.

This word is commonly applied to that grand period or cataſtrophe of our world, when the face of nature is to be changed by fire, as formerly it was by water.

CONFLUENT, among phyſicians, *&c.* an appellation given to that kind of ſmall-pox wherein the puſtules run into each other. See MEDICINE.

CONFORMATION, the particular conſiſtence and texture of the parts of any body, and their diſpoſition to compoſe a whole.

CONFORMATION, in medicine, that make and conſtruction of the human body, which is peculiar to every individual.

CONFORMITY, among ſchoolmen, the relation of agreement between one thing and another; as that between any thing and the diviſion thereof, the object and the underſtanding, *&c.*

CONFUSION, in Scots law, is a method of extinguiſhing and ſuſpending obligations. See SCOTS LAW, title, *Extinction of obligations*.

CONGE' *d'lire*, in eccleſiaſtical polity, the king's permiſſion royal to a dean and chapter in the time of a vacancy, to chuſe a biſhop; or to an abbey, or priory, of his own foundation, to chuſe their abbot or prior.

The king of England, as ſovereign patron of all archbiſhoprics, biſhoprics, and other eccleſiaſtical benefices, had of ancient time free appointment of all eccleſiaſtical dignities, whenſoever they chanced to be void; inveſting them firſt *per bacculum & annulum*, and afterwards by his letters-patent; and in courſe of time he made the election over to others, under certain forms and limitations, as that they ſhould at every vacation, before they chuſe, demand the king's congé d'lire, and after the election crave his royal aſſent, *&c.*

CONGE', in architecture, a mould in form of a quarter round or a cavetto, which ſerves to ſeparate two members from one another, ſuch as that which joins the ſhaft of the column to the cincture, called alſo apophyge.

CONGES are alſo rings or ferrels formerly uſed in the extremities of wooden pillars, to keep them from ſplitting, afterwards imitated in ſtone-work.

CONGELATION, freezing, or ſuch a change produced by cold in a fluid body, that it quits its former ſtate, and becomes congealed. See FREEZING.

CONGER, in zoology. See MURÆNA.

CONGERIES, a conſtellation or aggregate of ſeveral particles or bodies united into one maſs.

CONGIUS, a liquid meaſure of the ancient Romans, containing the eighth part of the amphora, or the fourth of the urna, or ſix ſextarii. The congius in Engliſh meaſure contains 2,070 676 ſolid inches; that is, ſeven pints, 4,942 ſolid inches.

CONGLOBATE *gland*, in anatomy. See Vol. I. p. 263.

CONGLOMERATE *gland*, in anatomy. See Vol. I. p. 265. *bottom*.

CONGLUTINATION, the gluing or faſtening any two bodies together by the intromiſſion of a third, whoſe parts are unctuous and tenacious, in the nature of glue. See GLUE.

CONGO, a large country on the weſtern coaſt of Africa, between 10° and 20° E. long. and between the equator and 18° S. lat. comprehending the countries of Loango, Angola, and Benguella. It is bounded by the kingdom of Benin on the north; by Mataman, a part of Caffraria, on the ſouth; and by the Atlantic ocean, on the weſt; and is ſometimes called the lower Guinea.

CONGREGATION, an aſſembly of ſeveral eccleſiaſtics united, ſo as to conſtitute one body; as an aſſembly of cardinals, in the conſtitution of the pope's court, met for the diſpatch of ſome particular buſineſs.

Theſe aſſemblies, being ſixteen in number, are diſtributed

ftributed into feveral chambers, after the manner of our offices and courts: the firft whereof is the pope's congregation, whofe bufinefs it is to prepare the moft difficult beneficiary matters to be afterward debated in the confiftory: the fecond is the congregation of the holy office, or the inquifition: the third is the congregation *de propaganda fide:* the fourth is the congregation for explaining the council of Trent: the fifth is the congregation of the index, deputed to examine into pernicious and heretical books: the fixth is the congregation of immunities, eftablifhed to obviate the difficulties that arife in the judgments of fuch fuits as are carried on againft churchmen: the feventh is the congregation of bifhops and regulars: the eighth is the congregation for the examination of bifhops, *&c.* It is alfo ufed for a company or fociety of religious, cantoned out of any order, fo as to make a fubdivifion of the order itfelf; as the congregation of Cluny, *&c.* among the Benedictines. It is likewife ufed for affemblies of pious perfons, in manner of fraternities.

CONGREGATIONALISTS, in church-hiftory, a fect of proteftants who reject all church-government, except that of a fingle congregation.

CONGRESS, in political affairs, an affembly of commiffioners, envoys, deputies, *&c.* from feveral courts meeting to concert matters for their common good.

CONGRESS, in a judicial fenfe, the trial made by appointment of a judge, before furgeons and matrons, in order to prove whether or no a man be impotent, before fentence is paffed for the diffolution of a marriage, folicited upon fuch a complaint.

CONGRUITY, a fuitablenefs or relation of agreement between things.

The terms *congruity* and *propriety* are not applicable to any fingle object: they imply a plurality, and obvioufly fignify a particular relation between different objects. Thus we fay currently, that a decent garb is fuitable or proper for a judge; modeft behaviour for a young woman, and a lofty ftyle for an epic poem: and, on the other hand, that it is unfuitable or incongruous to fee a little woman funk in an overgrown farthingale, a coat richly embroidered covering coarfe and dirty linen, a mean fubject in an elevated ftyle, an elevated fubject in a mean ftyle, a firft minifter darning his wife's ftocking, or a reverend prelate in lawn fleeves dancing a hornpipe.

The perception we have of this relation, which feems peculiar to man, cannot proceed from any other caufe, but from a *fenfe* of congruity or propriety; for, fuppofing us deftitute of that fenfe, the terms would be to us unintelligible.

It is a matter of experience, that congruity or propriety, where-ever perceived, is agreeable; and that incongruity or impropriety, where-ever perceived, is difagreeable. The only difficulty is, to afcertain what are the particular objects that in conjunction fuggefts thefe relations; for there are many objects that do not: the fea, for example, viewed in conjunction with a picture, or a man viewed in conjunction with a mountain, fuggeft not either congruity or incongruity. It feems natural to infer, what will be found true by induction, that we never perceive congruity nor incongruity but among things that are connected together by fome relation; fuch as a man and his actions, a principal and its acceffories, a fubject and its ornaments. We are indeed fo framed by nature, as among things fo connected, to require a certain fuitablenefs or correfpondence, termed *congruity* or *propriety*; and to be difpleafed when we find the oppofite relation of *incongruity* or *impropriety.*

If things connected be the fubject of congruity, it is reafonable beforehand to expect, that a degree of congruity fhould be required proportioned to the degree of the connection. And upon examination we find this to hold in fact: where the relation is intimate, as between a caufe and its effect, a whole and its parts, we require the ftricteft congruity; but where the relation is flight, or accidental, as among things jumbled together in the fame place, we require little or no congruity: the ftricteft propriety is required in behaviour and manner of living; becaufe a man is connected with thefe by the relation of caufe and effect: the relation between an edifice and the ground it ftands upon, is of the moft intimate kind, and therefore the fituation of a great houfe ought to be lofty; its relation to neighbouring hills, rivers, plains, being that of propinquity only, demands but a fmall fhare of congruity: among members of the fame club, the congruity ought to be confiderable, as well as among things placed for fhow in the fame niche: among paffengers in a ftage-coach, we require very little congruity; and lefs ftill at a public fpectacle.

Congruity is fo nearly allied to beauty, as commonly to be held a fpecies of it; and yet they differ fo effentially, as never to coincide: beauty, like colour, is placed upon a fingle fubject; congruity upon a plurality: further, a thing beautiful in itfelf, may, with relation to other things, produce the ftrongeft fenfe of incongruity.

Congruity and propriety are commonly reckoned fynonymous terms; but they are diftinguifhable; and the precife meaning of each muft be afcertained. Congruity is the genus, of which propriety is a fpecies; for we call nothing *propriety*, but that congruity or fuitablenefs, which ought to fubfift between fenfible beings and their thoughts, words, and actions.

In order to give a full view of thefe fecondary relations, we fhall trace them through fome of the moft confiderable primary relations. The relation of a part to the whole, being extremely intimate, demands the utmoft degree of congruity; even the flighteft deviation is difguftful.

Examples of congruity and incongruity are furnifhed in plenty by the relation between a fubject and its ornaments. A literary performance intended merely for amufement, is fufceptible of much ornament, as well as a mufic room, or a play-houfe; for in gaiety, the mind hath a peculiar relifh for fhow and decoration. The moft gorgeous apparel, however improper in tragedy, is not unfuitable to opera-actors: the truth is, an opera, in its prefent form, is a mighty fine thing; but as it deviates from nature in its capital circumftances, we look not for nature

nor

nor propriety in thoſe which are acceſſory. On the other hand, a ſerious and important ſubject admits not much ornament; nor a ſubject that of itſelf is extremely beautiful: and a ſubject that fills the mind with its loftineſs and grandeur, appears beſt in a dreſs altogether plain.

To a perſon of a mean appearance, gorgeous apparel is unſuitable; which, beſides the incongruity, has a bad effect; for by conſtraſt it ſhows the meanneſs of appearance in the ſtrongeſt light. Sweetneſs of look and manner, requires ſimplicity of dreſs joined with the greateſt elegance. A ſtately and majeſtic air requires ſumptuous apparel, which ought not to be gaudy, nor crouded with little ornaments. A woman of conſummate beauty can bear to be highly adorned, and yet ſhows beſt in a plain dreſs:

——————— For lovelineſs
Needs not the foreign aid of ornament,
But is when unadorn'd, adorn'd the moſt.

Thomſon's Autumn, 208.

Congruity regulates not only the quantity of ornament, but alſo the kind. The ornaments that embelliſh a dancing-room ought to be all of them gay. No picture is proper for a church, but what has religion for its ſubject. All the ornaments upon a ſhield ought to relate to war; and Virgil, with great judgment, confines the carvings upon the ſhield of Æneas to the military hiſtory of the Romans: but this beauty is overlooked by Homer; for the bulk of the ſculpture upon the ſhield of Achilles, is of the arts of peace in general, and of joy and feſtivity in particular: the author of Telemachus betrays the ſame inattention, in deſcribing the ſhield of that young hero.

In judging of propriety with regard to ornaments, we muſt attend, not only to the nature of the ſubject that is to be adorned, but alſo to the circumſtances in which it is placed: the ornaments that are proper for a ball, will appear not altogether ſo decent at public worſhip; and the ſame perſon ought to dreſs differently for a marriage-feaſt and for a burial.

Nothing is more intimately related to a man, than his ſentiments, words, and actions; and therefore we require here the ſtricteſt conformity. When we find what we thus require, we have a lively ſenſe of propriety: when we find the contrary, our ſenſe of impropriety is not leſs lively. Hence the univerſal diſtaſte of affectation, which conſiſts in making a ſhew of greater delicacy and refinement than is ſuited either to the character or circumſtances of the perſon.

Congruity and propriety, where-ever perceived, appear agreeable; and every agreeable object produceth in the mind a pleaſant emotion: incongruity and impropriety, on the other hand, are diſagreeable; and of courſe produce painful emotions. Theſe emotions, whether pleaſant or painful, ſometimes vaniſh without any conſequence; but more frequently occaſion other emotions, which we proceed to exemplify.

When any ſlight incongruity is perceived, in an accidental combination of perſons or things, as of paſſengers in a ſtage-coach, or of individuals dining at an ordinary; the painful emotion of incongruity, after a momentary exiſtence, vaniſheth without producing any effect. But this is not the caſe of propriety and impropriety: voluntary acts, whether words or deeds, are imputed to the author; when proper, we reward him with our eſteem; when improper, we puniſh him with our contempt. Let us ſuppoſe, for example, a generous action ſuited to the character of the author, which raiſes in him and in every ſpectator the pleaſant emotion of propriety: this emotion generates in the author both ſelf-eſteem and joy; the former when he conſiders his relation to the action, and the latter when he conſiders the good opinion that others will entertain of him: the ſame emotion of propriety produceth in the ſpectators eſteem for the author of the action; and when they think of themſelves, it alſo produceth, by means of contraſt, an emotion of humility. To diſcover the effects of an unſuitable action, we muſt invert each of theſe circumſtances: the painful emotion of impropriety generates in the author of the action both humility and ſhame; the former when he conſiders his relation to the action, and the latter when he conſiders what others will think of him: the ſame emotion of impropriety produceth in the ſpectators contempt for the author of the action; and it alſo produceth, by means of contraſt, when they think of themſelves, an emotion of ſelf-eſteem. Here then are many different emotions, derived from the ſame action conſidered in different views by different perſons; a machine provided with many ſprings, and not a little complicated. Propriety of action, it would ſeem, is a chief favourite of nature, when ſuch care and ſolicitude is beſtowed upon it. It is not left to our own choice; but, like juſtice, is required at our hands; and, like juſtice, is inforced by natural rewards and puniſhments: a man cannot, with impunity, do any thing unbecoming or improper; he ſuffers the chaſtiſement of contempt inflicted by others, and of ſhame inflicted by himſelf. An apparatus ſo complicated, and ſo ſingular, ought to rouſe our attention: for nature doth nothing in vain; and we may conclude with great certainty, that this curious branch of the human conſtitution is intended for ſome valuable purpoſe.

A groſs impropriety is puniſhed with contempt and indignation, which are vented againſt the offender by correſponding external expreſſions: nor is even the ſlighteſt impropriety ſuffered to paſs without ſome degree of contempt. But there are improprieties, of the ſlighter kind, that provoke laughter; of which we have examples without end, in the blunders and abſurdities of our own ſpecies: ſuch improprieties receive a different puniſhment, as will appear by what follows. The emotions of contempt and of laughter occaſioned by an impropriety of this kind, uniting intimately in the mind of the ſpectator, are expreſſed externally by a peculiar ſort of laugh, termed *a laugh of deriſion* or *ſcorn*. An impropriety that thus moves not only contempt but laughter, is diſtinguiſhed by the epithet of *ridiculous*; and a laugh of deriſion or ſcorn is the puniſhment provided for it by nature. Nor ought it to eſcape obſervation, that we are ſo fond of inflicting this puniſhment, as ſometimes to exert it even againſt creatures of an inferior ſpecies: witneſs a turkycock ſwelling with pride, and ſtrutting with diſplayed feathers; a ridiculous object, which in a gay mood is apt to provoke a laugh of deriſion.

We

We muſt not expect, that theſe different improprieties are ſeparated by diſtinct boundaries: for of improprieties, from the ſlighteſt to the moſt groſs, from the moſt riſible to the moſt ſerious, there are degrees without end. Hence it is, that in viewing ſome unbecoming actions, too riſible for anger, and too ſerious for deriſion, the ſpectator feels a ſort of mixt emotion, partaking both of deriſion and of anger; which accounts for an expreſſion, common with reſpect to the impropriety of ſome actions, That we know not whether to laugh or be angry.

It cannot fail to be obſerved, that in the caſe of a riſible impropriety, which is always ſlight, the contempt we have for the offender is extremely faint, though deriſion, its gratification, is extremely pleaſant. This diſproportion between a paſſion and its gratification, ſeems not conformable to the analogy of nature. In looking about for a ſolution, we muſt reflect upon what is laid down above, that an improper action not only moves our contempt for the author, but alſo, by means of contraſt, ſwells the good opinion we have of ourſelves. This contributes, more than any other article, to the pleaſure we have in ridiculing follies and abſurdities; and accordingly, it is well known, that they who put the greateſt value upon themſelves are the moſt prone to laugh at others. Pride, which is a vivid paſſion, pleaſant in itſelf, and not leſs ſo in its gratification, would ſingly be ſufficient to account for the pleaſure of ridicule, without borrowing any aid from contempt. Hence appears the reaſon of a noted obſervation, That we are the moſt diſpoſed to ridicule the blunders and abſurdities of others, when we are in high ſpirits; for in high ſpirits, ſelf-conceit diſplays itſelf with more than ordinary vigour.

With regard to the final cauſes of congruity and impropriety; one, regarding congruity, is pretty obvious, that the ſenſe of congruity, as one principle of the fine arts, contributes in a remarkable degree to our entertainment. Congruity, indeed, with reſpect to quantity, coincides with proportion: when the parts of a building are nicely adjuſted to each other, it may be ſaid indifferently, that it is agreeable by the congruity of its parts, or by the proportion of its parts. But propriety, which regards voluntary agents only, can never be the ſame with proportion: a very long noſe is diſproportioned, but cannot be termed *improper*. In ſome inſtances, it is true, impropriety coincides with diſproportion in the ſame ſubject, but never in the ſame reſpect; for example, a very little man buckled to a long toledo: conſidering the man and the ſword with reſpect to ſize, we perceive a diſproportion; conſidering the ſword as the choice of the man, we perceive an impropriety.

The ſenſe of impropriety with reſpect to miſtakes, blunders, and abſurdities, is happily contrived for the good of mankind. In the ſpectators, it is productive of mirth and laughter, excellent recreation in an interval from buſineſs. But this is a trifle in reſpect of what follows. It is painful to be the ſubject of ridicule; and to puniſh with ridicule the man who is guilty of an abſurdity, tends to put him more upon his guard in time coming. Thus even the moſt innocent blunder is not committed with impunity; becauſe, were errors licenſed where they do no hurt, inattention would grow into a habit, and be the occaſion of much hurt.

The final cauſe of propriety as to moral duties, is of all the moſt illuſtrious. To have a juſt notion of it, the moral duties that reſpect others muſt be diſtinguiſhed from thoſe that reſpect ourſelves. Fidelity, gratitude, and the forbearing injury, are examples of the firſt ſort; temperance, modeſty, firmneſs of mind, are examples of the other: the former are made duties by the ſenſe of juſtice; the latter by the ſenſe of propriety. Here is a final cauſe of the ſenſe of propriety, that muſt rouſe our attention. It is undoubtedly the intereſt of every man, to ſuit his behaviour to the dignity of his nature, and to the ſtation allotted him by Providence; for ſuch rational conduct contributes in every reſpect to happineſs, by preſerving health, by procuring plenty, by gaining the eſteem of others, and, which of all is the greateſt bleſſing, by gaining a juſtly-founded ſelf-eſteem. But in a matter ſo eſſential to our well-being, even ſelf-intereſt is not relied on: the powerful authority of duty is ſuperadded to the motive of intereſt. The God of nature, in all things eſſential to our happineſs, hath obſerved one uniform method: to keep us ſteady in our conduct, he hath fortified us with natural laws and principles, which prevent many aberrations, that would daily happen were we totally ſurrendered to ſo fallible a guide as is human reaſon. Propriety cannot rightly be conſidered in another light, than as the natural law that regulates our conduct with reſpect to ourſelves; as juſtice is the natural law that regulates our conduct with reſpect to others. We call propriety a law, not leſs than juſtice; becauſe both are equally rules of conduct that ought to be obeyed: propriety includes this obligation; for to ſay an action is proper, is, in other words, to ſay, that it *ought* to be performed; and to ſay it is improper, is, in other words, to ſay that it *ought* to be forborn. It is this very character of *ought* and *ſhould* that makes juſtice a law to us; and the ſame character is applicable to propriety, though perhaps more faintly than to juſtice: but the difference is in degree only, not in kind; and we ought, without heſitation or reluctance, to ſubmit equally to the government of both.

But it muſt, in the next place, be obſerved, that to the ſenſe of propriety, as well as of juſtice, are annexed the ſanctions of rewards and puniſhments; which evidently prove the one to be a law as well as the other. The ſatisfaction a man hath in doing his duty, joined with the eſteem and good will of others, is the reward that belongs to both equally. The puniſhments alſo, though not the ſame, are nearly allied; and differ in degree more than in quality. Diſobedience to the law of juſtice, is puniſhed with remorſe; diſobedience to the law of propriety, with ſhame, which is remorſe in a lower degree. Every tranſgreſſion of the law of juſtice raiſes indignation in the beholder; and ſo doth every flagrant tranſgreſſion of the law of propriety. Slighter improprieties receive a milder puniſhment: they are always rebuked with ſome degree of contempt, and frequently with deriſion. In general, it is true, that the rewards and puniſhments annexed to the ſenſe of propriety, are ſlighter

ſlighter in degree than thoſe annexed to the ſenſe of juſtice: which is wiſely ordered, becauſe duty to others is ſtill more eſſential to ſociety, than duty to ourſelves; for ſociety could not ſubſt a moment, were individuals not protected from the headſtrong and turbulent paſſion of their neighbours.

CONI, a ſtrong town of Piedmont in Italy, ſituated upon the river Stura, thirty two miles ſouth of Turin, in 7° 30′ E. long. and 44° 25′ N. lat.

CONIC SECTIONS.

CONIC SECTIONS are curve lines formed by the interſections of a cone and plane.

If a cone be cut by a plane through the vertex, the ſection will be a triangle ABC, Plate LXVII. fig. 1.

If a cone be cut by a plane parallel to its baſe, the ſection will be a circle. If it be cut by a plane DEF, fig. 1. in ſuch a direction, that the ſide AC of a triangle paſſing through the vertex, and having its baſe BC perpendicular to EF, may be parallel to DP, the ſection is a parabola; if it be cut by a plane DR, fig. 2. meeting AC, the ſection is an ellipſe; and if it be cut by a plane DMO, fig. 3. which would meet AC extended beyond A, it is an hyperbola.

If any line HG, fig. 1. be drawn in a parabola perpendicular to DP, the ſquare of HG will be to the ſquare of EP, as DG to DP; for let LHK be a ſection parallel to the baſe, and therefore a circle, the rectangle LGK, will be equal to the ſquare of HG, and the rectangle BPC equal to the ſquare of EP; therefore theſe ſquares will be to each other as their rectangles; that is, as BP to LG, that is DP to DG.

Deſcription of Conic Sections on a Plane.

PARABOLA.

"Let AB, fig. 4. be any right line, and C any point "without it, and DKF a ruler, which let be placed "in ſame plane in which the right line and point are, "in ſuch a manner that one ſide of it, as DK, be applied "to the right line AB, and the other ſide KF coincide "with the point C; and at F, the extremity of the ſide "KF, let be fixed one end of the thread FNC, whoſe "length is equal to KF, and the other extremity of it "at the point C, and let part of the thread, as FG, be "brought cloſe to the ſide KF by a ſmall pin G; then "let the ſquare DKF be moved from B towards A, ſo "that all the while its ſide DK be applied cloſe to the "line BA, and in the mean time the thread being ex"tended will always be applied to the ſide KF, being "ſtopt from going from it by means of the ſmall pin; "and by the motion of the ſmall pin N there will be de"ſcribed a certain curve, which is called a *ſemi para"bola*.

"And if the ſquare be brought to its firſt given poſi"tion, and in the ſame manner be moved along the line "AB, from B towards H, the other ſemi-parabola will "be deſcribed."

The line AB is called the directrix; C, the focus; any line perpendicular to AB, a diameter; the point where it meets the curve, its vertex; and four times the diſtance of the vertex from the directrix, its latus rectum, or parameter.

ELLIPSE.

"If any two points, as A and B, fig. 5. be taken in "any plane, and in them are fixed the extremities of a "thread, whoſe length is greater than the diſtance be"tween the points, and the thread extended by means "of a ſmall pin C, and if the pin be moved round from "any point until it return to the place from whence it "began to move, the thread being extended during the "whole time of the revolution, the figure which the "ſmall pin by this revolution deſcribes is called an *El"lipſe*."

The points AB are called the foci; D, the centre; EF, the tranſverſe axis; GH, the leſſer axis; and any other line paſſing through D, a diameter.

HYPERBOLA.

"If to the point A, fig. 6. in any plane, one end of the "rule AB be placed, in ſuch a manner, that about that "point, as a center, it may freely move; and if to the "other end B, of the rule AB, be fixed the extremity "of the thread BDC, whoſe length is ſmaller than the "rule AB, and the other end of the thread being fixed "in the point C, coinciding with the ſide of the rule "AB, which is in the ſame plane with the given point "A; and let part of the thread, as BD, be brought "cloſe to the ſide of the rule AB, by means of a ſmall "pin D; then let the rule be moved about the point A, "from C towards T, the thread all the while being ex"tended, and the remaining part coinciding with the "ſide of the rule being ſtopt from going from it by "means of the ſmall pin, and by the motion of the ſmall "pin D, a certain figure is deſcribed which is called "the *ſemi-hyperbola*."

The other ſemi-hyperbola is deſcribed in the ſame way, and the oppoſite HKF, by fixing the ruler to C, and the thread to A, and deſcribing it in the ſame manner. A and C are called foci; the point G, which biſects AC, the center; KE, the traſverſe axis; a line drawn through the center meeting the hyperbolas, a tranſverſe diameter; a line drawn through the center, perpendicular to the tranſverſe axis, and cut off by the circle MN, whoſe center is E, and radius equal to CG, is called the ſecond axis.

If a line be drawn through the vertex E, equal and parallel to the ſecond axis GP and GO be joined, they are called aſſymptotes. Any line drawn through the center, not meeting the hyperbolas, and equal in length to the part

part of a tangent parallel to it, and intercepted betwixt the aſſymptotes, is called a ſecond diameter.

An ordinate to any ſection is a line biſected by a diameter and the abſciſſa, the part of the diameter cut off by the ordinate.

Conjugate diameters in the ellipſe and hyperbola are ſuch as mutually biſect lines parallel to the other; and a third proportional to two conjugate diameters is called the latus rectum of that diameter, which is the firſt in the proportion.

In the parabola, the lines drawn from any point to the focus are equal to perpendiculars to the directrix; being both equal to the part of the thread ſeparated from the ruler.

In the ellipſe, the two lines drawn from any point in the curve to the foci are equal to each other, being equal to the length of the thread; they are alſo equal to the tranſverſe axis. In the hyperbola the difference of the lines drawn from any point to the foci is equal, being equal to the difference of the lengths of the ruler and thread, and is equal to the tranſverſe axis.

From theſe fundamental properties all the others are derived.

The ellipſe returns into itſelf. The parabola and hyperbola may be extended without limit.

Every line perpendicular to the directrix of a parabola meets it in one point, and falls afterwards within it; and every line drawn from the focus meets it in one point, and falls afterwards without it. And every line that paſſes through a parabola, not perpendicular to the directrix, will meet it again, but only once.

Every line paſſing through the center of an ellipſe is biſected by it; the tranſverſe axis is the greateſt of all theſe lines; the leſſer axis the leaſt; and theſe nearer the tranſverſe axis greater than thoſe more remote.

In the hyperbola, every line paſſing through the center is biſected by the oppoſite hyperbola, and the tranſverſe axis is the leaſt of all theſe lines; alſo the ſecond axis is the leaſt of all the ſecond diameters. Every line drawn from the center within the angle contained by the aſſymptotes, meets it once, and falls afterwards within it; and every line drawn through the center without that angle never meets it; and a line which cuts one of the aſſymptotes, and cuts the other extended beyond the center, will meet both the oppoſite hyperbolas in one point.

If a line G M, fig. 4. be drawn from a point in a parabola perpendicular to the axis, it will be an ordinate to the axis, and its ſquare will be equal to the rectangle under the abſciſſa MI and latus rectum; for, becauſe GMC is a right angle, GM^q is equal to the difference of GC^q and CM^q; but GC is equal to GE, which is equal to MB; therefore GM^q is equal to $BM^q—CM^q$; which, becauſe CI and IB are equal, is (8 *Euc.* 2.) equal to four times the rectangle under MI and IB, or equal to the rectangle under MI and the *latus rectum*.

Hence it follows, that if different ordinates be drawn to the axis, their ſquares being each equal to the rectangle under the abſciſſa and latus rectum, will be to each other in the proportion of the abſciſſas, which is the ſame property as was ſhewn before to take place in the parabola cut from the cone, and proves thoſe curves to be the ſame.

This property is extended alſo to the ordinates of other diameters, whoſe ſquares are equal to the rectangle under the abſciſſas and parameters of their reſpective diameters.

In the ellipſe, the ſquare of the ordinate is to the rectangle under the ſegments of the diameter, as the ſquare of the diameter parallel to the ordinate to the ſquare of the diameter to which it is drawn, or as the firſt diameter to its latus rectum; that is, LK^q (fig. 5.) is to EKF as EF^q to GH^q.

In the hyperbola, the ſquare of the ordinate is to the rectangle contained under the ſegments of the diameters betwixt its vertices, as the ſquare of the diameter parallel to the ordinate to the ſquare of the diameter to which it is drawn, or as the firſt diameter to its *latus rectum*; that is, SX^q is to EXK as MN^q to KE^q.

Or if an ordinate be drawn to a ſecond diameter, its ſquare will be to the ſum of the ſquares of the ſecond diameter, and of the line intercepted betwixt the ordinate and centre, in the ſame proportion; that is, RZ^q (fig. 6.) is to ZG^q added to GM^q, as KE^q to MN^q. Theſe are the moſt important properties of the conic ſections: and, by means of theſe, it is demonſtrated, that the figures are the ſame deſcribed on a plane as cut from the cone; which we have demonſtrated in the caſe of the parabola.

Equations of the Conic Sections

Are derived from the above properties. The equation of any curve, is an algebraic expreſſion, which denotes the relation betwixt the ordinate and abſciſſa; the abſciſſa being equal to x, and the ordinate equal to y.

If p be the parameter of a parabola, then $y^2=px$; which is an equation for all parabolas.

If a be the diameter of an ellipſe, p its parameter; then $y^2 : ax-xx :: p : a$; and $y^2=\frac{p}{a}\times\overline{ax-xx}$; an equation for all ellipſes.

If a be a tranſeverſe diameter of a hyperbola, p its parameter; then $y^2 : ax+xx :: p : a$, and $y^2=\frac{p}{a}\times\overline{ax+xx}$.

If a be a ſecond diameter of an hyperbola, then $y^2 = aa+xx :: p : a$; and $y^2=\frac{p}{a}\times aa+xx$; which are equations for all hyperbolas.

As all theſe equations are expreſſed by the ſecond powers of x and y, all conic ſections are curves of the ſecond order; and converſely, the locus of every quadratic equation is a conic ſection, and is a parabola, ellipſe, or hyperbola, according as the form of the equation correſponds with the above ones, or with ſome other deduced from lines drawn in a different manner with reſpect to the ſection.

General Properties of Conic Sections.

A Tangent to a parabola biſects the angle contained by the lines drawn to the focus and directrix; in an ellipſe

ellipse and hyperbola, it bisects the angle contained by the lines drawn to the foci.

In all the sections, lines parallel to the tangent are ordinates to the diameter passing through the point of contact; and in the ellipse and hyperbola, the diameters parallel to the tangent, and those passing through the points of contact, are mutually conjugate to each other. If an ordinate be drawn from a point to a diameter and a tangent from the same point which meets the diameter produced; in the parabola the part of the diameter betwixt the ordinate and tangent will be bisected in the vertex; and in the ellipse and hyperbola, the semi-diameter will be a mean proportion betwixt the segments of the diameter betwixt the center and ordinate, and betwixt the centre and tangent.

The parallelogram formed by tangents drawn through the vertices of any conjugate diameters, in the same ellipse or hyperbola, will be equal to each other.

Properties peculiar to the Hyperbola.

As the hyperbola has some curious properties arising from its assymptotes, which appear at first view almost incredible, we shall briefly demonstrate them.

1. The hyperbola and its assymptotes never meet: if not, let them meet in S, fig. 6.; then by the property of the curve the rectangle KXE is to SX^q as GE^q to GM^q or EP^q; that is, as GX^q to SX^q; wherefore, KXE will be equal to the square of GX; but the rectangle KXE, together with the square of GE, is also equal to the square of GX; which is absurd.

2. If a line be drawn through a hyperbola parallel to its second axis, the rectangle, by the segments of that line, betwixt the point in the hyperbola and the assymptotes, will be equal to the square of the second axis.

For, if SZ, fig. 6. be drawn perpendicular to the second axis, by the property of the curve, the square of MG, that is, the square of PE, is to the square of GE, as the squares of ZG and the square of MG together, to the square of SZ or GX: and the squares of RX and GX are in the same proportion, because the triangles RXG, PEG are equiangular; therefore the squares ZG and MG are equal to the square of RX; from which taking the equal squares of SX and ZG, there remains the rectangle RSV, equal to the square of MG.

3. Hence, if right lines be drawn parallel to the second axis, cutting an hyperbola and its assymptotes, the rectangles contained betwixt the hyperbola and points where the lines cut the assymptotes will be equal to each other; for they are severally equal to the square of the second axis.

4. If from any points, d and S, in a hyperbola, there be drawn lines parallel to the assymptotes da SQ and Sb dc, the rectangle under da and dc will be equal to the rectangle under QS and Sb; also the parallelograms da, Gc, and SQGb, which are equiangular, and consequently proportional to the rectangles, are equal.

For draw YW RV parallel to the second axis, the rectangle YdW is equal to the rectangle RSV; wherefore, WD is to SV as RS is to dY. But because the triangles RQS, AYD, and GSV cdW, are equiangular, Wd is to SV as cd to Sb, and RS is to DY as SQ to da; wherefore, dc is to Sb as SQ to da: and the rectangle dc, da, is equal to the rectangle QS, Sb.

5. The assymptotes always approach nearer the hyperbola.

For, because the rectangle under SQ and Sb, or QG, is equal to the rectangle under da and dc, or AG, and QG is greater than aG; therefore ad is greater than QS.

6. The assymptotes come nearer the hyperbola than any assignable distance.

Let X be any small line. Take any point, as d, in the hyperbola, and draw da, dc, parallel to the assymptotes; and as X is to da, so let aG be to GQ. Draw QS parallel to ad, meeting the hyperbola in S, then QS will be equal to X. For the rectangle SQG will be equal to the rectangle daG; and consequently SQ is to da as AG to GQ.

If any point be taken in the assymptote below Q, it can easily be shown that its distance is less than the line X.

Areas contained by Conic Sections.

THE area of a parabola is equal to $\frac{2}{3}$ the area of a circumscribed paralellogram.

The area of an ellipse is equal to the area of a circle whose diameter is a mean proportional betwixt its greater and lesser axes.

If two lines, ad and QS, be drawn parallel to one of the assymptotes of an hyperbola, the space aQSd, bounded by these parallel lines, the assymptotes and the hyperbola will be equal to the logarithm of aQ, whose module is ad, supposing aG equal to unity.

Curvature of Conic Sections.

THE curvature of any conic section, at the vertices of its axis, is equal to the curvature of a circle whose diameter is equal to the parameter of its axis.

If a tangent be drawn from any other point of a conic section, the curvature of the section in that point will be equal to the curvature of a circle to which the same line is a tangent, and which cuts off from the diameter of the section, drawn through the point, a part equal to its parameter.

Uses of Conic Sections.

ANY body, projected from the surface of the earth, describes a parabola, to which the direction wherein it is projected is a tangent; and the distance of the directrix is equal to the height from which a body must fall to acquire the velocity wherewith it is projected: hence the properties of the parabola are the foundation of gunnery.

All bodies acted on by a central force, which decreases as the square of the distances increases, and impressed with any projectile motion, making any angle with the direction of the central force, must describe conic sections, having the central force in one of the foci, and will

Plate LXVII.

Fig. 1.

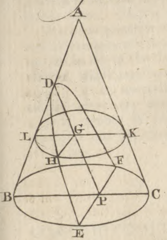

Fig. 2.

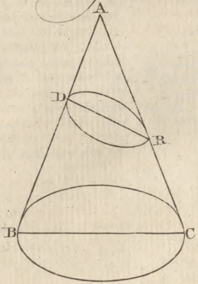

Fig. 3.

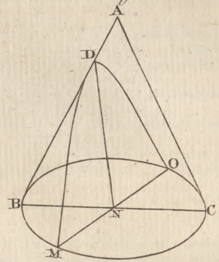

Fig. 4.

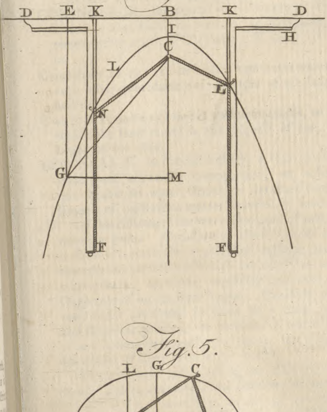

Fig. 6.

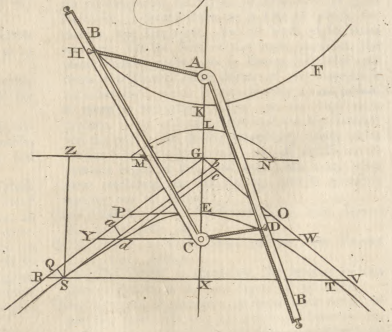

Fig. 5.

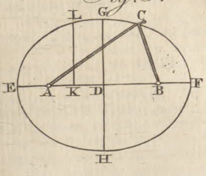

A. B. Sc.

will deſcribe parabolas, ellipſes, and hyperbolas, according to the proportion betwixt the central and projectile force. This is proved by direct demonſtration.

The great principle of gravitation acts in this manner; and all the heavenly bodies deſcribe conic ſections having the ſun in one of the foci; the orbits of the planets are ellipſes, whoſe tranſverſe and leſſer diameters are nearly equal; it is uncertain whether the comets deſcribe ellipſes with very unequal axes, and ſo return after a great number of years; or whether they deſcribe parabolas and hyperbolas, in which caſe they will never return.

Uſes of Conic Sections in the Solution of Geometrical Problems.

Many problems can be ſolved by conic ſections that cannot be ſolved by right lines and circles. The following theorems, which follow from the ſimpler properties of the ſections, will give a ſpecimen of this.

A point equally diſtant from a given point and a given line, is ſituated in a given parabola.

A point, the ſum of whoſe diſtances from two given points is given, is ſituated in a given ellipſe.

A point, the difference of whoſe diſtances from two given points is given, is ſituated in a given hyperbola.

CONICTHYODONTES, or Plectronitæ, in natural hiſtory, one of the three names the foſſile teeth of fiſhes are known by.

CONIFEROUS trees, ſuch as bear hard, dry ſeed-veſſels, of a conical figure, conſiſting of ſeveral woody parts, being moſtly ſcaly, adhering cloſely together, and ſeparating when ripe.

Of this ſort is the cedar of Lebanon, fir, *&c.*

CONINGSECK, the capital of a county of the ſame name, in the circle of Swabia, in Germany, about twenty miles north of Conſtance: E. long 9° 23′, N. lat. 47° 50′.

Conjoint degrees, in muſic, two notes which follow each other immediately in the order of the ſcale, as *ut* and *re*.

Conjoint tetrachords, two tetrachords, or fourths, where the ſame chord is the higheſt of one, and the loweſt of the other.

CONISSALÆ, in natural hiſtory, a claſs of foſſils, naturally and eſſentially compounded, not inflammable, nor ſoluble in water, found in detached maſſes, and formed of cryſtalline matter debaſed by earth.

Of this claſs there are two orders, and of each of theſe only one genus. Coniſſalæ of the firſt order are found in form of a naturally regular and uniform powder, all the genuine particles of which are nearly of one determinate ſhape, appearing regularly concreted, and not fragments of others once larger. Coniſſalæ of the ſecond order are found in form of a rude, irregular, and ſhapeleſs powder, the particles of which are never of any determinate particular figure, but ſeem broken fragments of ſome once larger maſſes.

To the former genus belong the different kinds of ſand; and to the latter, the ſaburræ, or gritts.

CONJUGATE diameter, or *axis of an ellipſis*, the ſhorteſt of the two diameters, or that biſecting the tranſverſe axis.

Conjugate hyperbolas. See Conicsections.

CONJUGATION, in grammar, a regular diſtribution of the ſeveral inflexions of verbs in their different voices, moods, tenſes, numbers and perſons, ſo as to diſtinguiſh them from one another.

The Latins have four conjugations, diſtinguiſhed by the terminations of the infinitive āre, ēre, ĕre, and īre.

The Engliſh have ſcarce any natural inflexions, deriving all their variations from additional particles, pronouns, *&c.* whence there is ſcarce any ſuch thing as ſtrict conjugations in that language.

CONIUM, in botany, a genus of the pentandria digynia claſs of plants. The fruit is globular, crenated on each ſide, and has five ſtriæ or ſtreaks. There are three ſpecies, only one of which, *viz.* the conium maculatum, or hemlock, is a native of Britain. Within theſe few years paſt Dr Stork publiſhed a treatiſe recommending the extract of hemlock to be given internally, in ſeveral doſes, as a kind of ſpecific for cancers, the king's-evil, and all kinds of ſchirrous tumours. On the faith of this ſingle phyſician, the whole medical practitioners in Europe doſed their patients who laboured under diſeaſes of the above kinds with hemlock, which is unqueſtionbly a rank poiſon, if taken to any extent. After two or three years practice, it was at length diſcovered that the hemlock was not poſſeſſed of thoſe extraordinary virtues which Dr Stork had attributed to it; and of courſe its reputation began to ſink, and now, like many other great medicines, has had its day, and is gradually wearing out of practice.

CONJUNCT *rights*. See Scots Law, title, *Succeſſion in heritable rights*.

CONJUNCT, or Confident perſons. See Scots Law, title, *Actions*.

CONJUNCTION, in aſtronomy, the meeting of two ſtars or planets, in the ſame degree of the zodiac.

Conjunction, in grammar, an undeclinable word, or particle, which ſerves to join words and ſentences together, and thereby ſhews their relation or dependence one upon another.

CONJUNCTIVA, in anatomy. See Vol. I. p. 291.

CONNAUGHT, the moſt weſterly province of Ireland.

CONNARUS, in botany, a genus of the monodelphia decandria claſs. It has but one ſtylus; the ſtigma is ſimple; and the capſule has two valves, and contains one ſeed. There is but one ſpecies, *viz.* the monocarpus, a native of India.

CONNECTICUT, a Britiſh colony of North America, bounded by the Maſſachuſet colony on the north-eaſt; by the ſea, on the ſouth; and by New York, on the weſt;

west; being about 100 miles in length, and 80 in breadth.

CONNECTION, or CONNEXION, the relation or dependence of one thing upon another.

CONNECTION, or CONTINUITY, in the drama, consists in the joining of the several scenes together.

The connection is said to be observed, when the scenes of an act succeed one another immediately, and are so joined as that the stage is never left empty.

CONNOISSEUR, a French word much used of late in English, to signify a person well versed in any thing: whence it is used for a critic, or a person who is a thorough judge of any subject.

CONNOR, a city of Ireland, in the county of Antrim, and province of Ulster, situated about six miles north of Antrim, in 6° 30′ W. long. and 54° 50′ N. lat.

CONOCARPODENDRON, in botany. See PROTEA.

CONOCARPUS, the BUTTON-TREE, in botany, a genus of the pentandria monogynia class. The corolla consists of four petals; the seeds are naked, solitary, and below the flower; and the flowers are aggregated. There are three species, all natives of the Indies.

CONOID, in geometry, a solid body, generated by the revolution of a conic section about its axis. See CONIC SECTIONS.

CONOIDES, in anatomy, a gland found in the third ventricle of the brain, called *pinealis*, from its resemblance to a pine-apple.

CONQUEST. See SCOTS LAW, title, *Succession in heritable rights*.

CONSANGUINITY, the relation subsisting between persons of the same blood, or who are sprung from the same root.

CONSANGUINITY and AFFINITY, degrees of, forbidden in marriage; see SCOTS LAW, title, *Marriage*. Consanguinity or affinity, an objection against a judge; see title, *Jurisdiction and judges*: Against a witness; see title, *Probation*.

CONSCIENCE, a secret testimony of the soul, whereby it gives its approbation to things that are naturally good, and condemns those that are evil. See MORALS.

CONSCRIPT, in Roman antiquity, an appellation given to the senators of Rome, who were called conscript-fathers on account of their names being entered all in one register.

CONSECRATION, the act of devoting any thing to the service and worship of God.

In England, churches have been always consecrated with particular ceremonies, the form of which was left to the discretion of the bishop.

CONSENT, in a general sense, denotes much the same with assent. See ASSENT.

CONSENT *of parts*, in the animal œconomy. See SYMPATHY.

CONSEQENCE, in logic, the conclusion, or what results from reason or argument.

CONSERVATOR, an officer ordained for the security and preservation of the privileges of some cities and communities. having a commission to judge of and determine the differences among them.

CONSERVATORY, a term sometimes used for a green-house, or ice-house.

CONSERVE, in pharmacy, a form of medicine, contrived to preserve the flowers, herbs, roots, pills, or fruits, of several simples, as near as possible to what they are when fresh gathered.

Conserves are made by beating up the thing to be preserved, with sugar, *viz.* a triple quantity thereof to those that are most moist, and a double quantity to those that are least so.

CONSIGNATION of money; see SCOTS LAW, title, *Obligations and contracts in general*: Of redemption-money; see title, *Redeemable rights*.

CONSISTENCE, in physics, that state of a body wherein its component particles are so connected or entangled among themselves, as not to separate or recede from each other. It differs from continuity in this, that it implies a regard to motion or rest, which continuity does not, it being sufficient to denominate a thing continuous that its parts are contiguous to each other.

CONSISTORIAL, or COMMISSARY COURT. See SCOTS LAW, title, *Ecclesiastical persons*.

CONSISTORY, at Rome, is an ecclesiastical assembly held in the presence of the pope, for the reception of princes or their ambassadors, for the canonization of saints, for the promotion of cardinals, and other important affairs.

CONSOLE, in architecture, an ornament cut upon the key of an arch, which has a projecture, and, on occasion, serves to support little corniches, figures, busts, and vases. See ARCHITECTURE.

CONSOLIDA, in botany. See AJUGA.

CONSOLIDATION, in medicine, the action of uniting broken bones, or the lips of wounds, by means of conglutinating medicines.

CONSONANCE, in music, is ordinarily used in the same sense with concord, *viz.* for the union or agreement of two sounds produced at the same time, the one grave and the other acute; which mingling in the air in a certain proportion, occasion an accord agreeable to the ear. See MUSIC.

CONSONANT, a letter that cannot be sounded without some single or double vowel before or after it, as b, c, d, *&c.*

CONSPIRACY, in law, signifies an agreement between two or more, falsely to indict, or procure to be indicted, an innocent person, of felony.

CONSPIRATORS are, by statute, defined to be such as bind themselves by oath, covenant, or other alliance, to assist one another falsely and maliciously to indict persons, or falsely to maintain pleas.

Conspirators in treason are those that plot against the king and the government.

CONSTABLE, Lord High Constable, an ancient officer of the crowns both of England and France, whose authority was so very extensive, that the office has been laid aside in both kingdoms, except upon particular occasions,

casions, ſuch as the king's coronation. The conſtable of France had his perſon privileged, and, during the king's minority, was named next to the princes of the blood. The army obeyed him next the king: he managed all that belonged to war, either for puniſhment of delinquents, diſtribution of booty, ſurrender of places, *&c.* The juriſdiction and functions of this office are now in the mareſchals of France.

The function of the conſtable of England conſiſted in the care of the common peace of the land, in deeds of arms and matters of war. By a law of Richard II. the conſtable of England has the determination of things concerning wars and blazonry of arms, which cannot be diſcuſſed by the common law. The firſt conſtable was created by the Conqueror: the office continued hereditary till the thirteenth of Henry VIII. when it was laid aſide, as being ſo powerful as to become troubleſome to the king. We have alſo conſtables denominated from particular places, as conſtable of the Tower, of Dover caſtle, of Windſor-caſtle, of the caſtle of Caernarvon, and many other of the caſtles of Wales, whoſe office is the ſame with that of the caſtellani, or governors of caſtles.

CONSTABLE *of Scotland.* See SCOTS LAW, title, *Of inferior judges.*

CONSTABLES *to juſtices of the peace,* in Scots law, are the proper officers for executing their orders. They have powers to ſuppreſs tumults, and to apprehend delinquents and thoſe who can give no good account of themſelves, and carry them to the next juſtice.

CONSTANCE, a city of Swabia, in Germany, ſituated on the weſtern ſhore of a lake to which it gives name, in 9° 12′ E. lon. and 47° 37′ N. lat.

It is the ſee of a biſhop, who is a prince of the German empire.

CONSTANTINA, the capital of a province of the ſame name, in the kingdom of Algiers, in Africa: E. long. 7°, and N. lat. 35° 30′.

CONSTANTINOPLE, the metropolis of the Turkiſh empire, called by the Turks themſelves Stamboul, and by many Europeans the Port, being one of the beſt harbours in Europe: E. long. 29° 15′, and N. lat. 41° 30′.

It is built on the weſtern ſhore of the Boſphorus, in the form of a triangle; the ſeraglio, or palace, occupying that angle which runs out between the Propontis and harbour; and underneath the palace are the gardens, which extend to the water-ſide.

CONSTELLATION, in aſtronomy. See Vol. I. p. 486.

CONSTIPATION, in medicine, a hardneſs of the belly, with great coſtiveneſs.

CONSTITUENT PART, in phyſiology, an eſſential part in the compoſition of any thing, differing little from what is otherwiſe called element or principle.

CONSTITUTION, in matters of policy, ſignifies the form of government eſtabliſhed in any country or kingdom.

CONSTITUTION alſo denotes an ordinance, deciſion, regulation, or law, made by authority of any ſuperior, eccleſiaſtical or civil.

Apoſtolical CONSTITUTIONS, a collection of regulations attributed to the apoſtles, and ſuppoſed to have been collected by St Clement, whoſe name they likewiſe bear.

It is the general opinion, however, that they are ſpurious, and that St Clement had no hand in them. They appeared firſt in the IVth age, but have been much changed and corrupted ſince that time. They are divided into eight books, conſiſting of a great number of rules and precepts, relating to the duties of Chriſtians, and particularly the ceremonies and diſcipline of the church. Mr Whiſton, in oppoſition to the general opinion, aſſerts them to be a part of the ſacred writings, dictated by the apoſtles in their meetings, and wrote down from their own mouth by St Clement, and intended as a ſupplement to the New Teſtament, or rather as a ſyſtem of Chriſtian faith and polity. The reaſon why the Conſtitutions are ſuſpected by the orthodox, and, perhaps, the reaſon alſo why their genuineneſs is defended by Mr Whiſton, is, that they ſeem to favour Arianiſm.

CONSTITUTION, in a phyſical ſenſe, ſignifies the particular temperature of the body.

CONSTRICTOR, an appellation given to ſeveral muſcles on account of their conſtringing or cloſing ſome of the orifices of the body. See ANATOMY.

CONSTRUCTION *of equations,* in Algebra. See ALGEBRA.

CONSTRUCTION, in grammar, the connecting the words of a ſentence according to the rules of the language.

CONSUALIA, in Roman antiquity, a feſtival inſtituted by Romulus, who, at the time of the rape of the Sabine virgins, found an altar under ground dedicated to the god Conſus, that is, Neptune. They were introduced with a magnificent cavalcade; and during the celebration, the horſes and aſſes were crowned with flowers, and a mule was ſacrificed to that god.

CONSUBSTANTIATION, a tenet of the Lutheran church with regard to the manner of the change made in the bread and wine in the euchriſt.

The divines of that profeſſion maintain, that after conſecration, the body and blood of our Saviour are ſubſtantially preſent, together with the ſubſtance of the bread and wine, which is called conſubſtantiation, or impanation.

CONSUL, the chief magiſtrate of the Roman commonwealth. They were two in number, choſen every year in the Campus Martius, by the people aſſembled in the comitia centuriata. In the firſt times of the commonwealth, no man could pretend to this dignity, but ſuch as were of a patrician family; but afterwards the people obtained, that one of the conſuls ſhould be choſen from among them. A conſul was commonly choſen at forty-three years of age, but this was not always obſerved: beſides, it was requiſite he ſhould have exerciſed other offices, as that of quæſtor, ædile, and prætor: and yet this condition was no better obſerved than the firſt; for Pompey had never been prætor nor quæſtor when he obtained the conſulſhip. Their authority and power was of very great extent, ſo long as the commonwealth ſubſiſted. They were the

the head of the ſenate: they commanded the armies, and were ſupreme judges of the differences between the citizens; but as they had made ſome abuſe of this power, it was allowed by the Valerian law for the party aggrieved to appeal from their tribunal to the people, eſpecially in caſes where the life of a citizen was concerned. Under the emperors, conſul was little more than an honourable title, and at laſt it became abſolutely extinct in the time of Juſtinian. From the eſtabliſhment of the republic to the conſulate of Baſil, that is, from the year of Rome 244, to the year of Rome 1294, the years are accounted by the conſuls; but after that period, the time was computed by the years of the emperors reigns and the indictions.

CONSUL, at preſent, is an officer eſtabliſhed by virtue of a commiſſion from the king and other princes, in all foreign countries of any conſiderable trade, to facilitate and diſpatch buſineſs, and protect the merchants of the nation. The conſuls are to keep up a correſpondence with the miniſters of England reſiding in the courts whereon their conſulate depends. They are to ſupport the commerce and the intereſt of the nation; to diſpoſe of the ſums given and the preſents made to the lords and principals of places, to obtain their protection, and prevent the inſults of the natives on the merchants of the nation.

CONSUMMATION, the end or completion of the work. Thus we ſay, the conſummation of all things, meaning the world.

CONSUMPTION, in medicine, a word of very extenſive ſignification, implies all diſorders that bring any decay or waſte upon the conſtitution; but is moſt uſed for the phthiſis pulmonalis. See MEDICINE.

CONTACT, is when one line, plane, or body, is made to touch another, and the parts that do thus touch, are called the points or places of contact.

CONTAGION, in phyſic, the communicating a diſeaſe from one body to another. In ſome diſeaſes it is only effected by an immediate contact or touch, as the venom of the pox; in others, it is conveyed by infected cloaths, as the itch; and in others, it is tranſmitted through the air at a conſiderable diſtance, by means of ſteams or effluvia expiring from the ſick, as in the plague and other peſtilential diſorders, in which caſe the air is ſaid to be contagious.

CONTEMPLATION, an act of the mind, whereby it applies itſelf to conſider and reflect upon the works of God, nature, *&c.*

CONTEMPORARY, a perſon or thing that exiſted in the ſame age with another. Thus, Socrates, Plato, and Ariſtophanes, were contemporaries.

CONTENT, in geometry, the area or quantity of matter or ſpace included in certain bounds. See GEOMETRY.

CONTESSA, a port-town of Turkey, in Europe, in the province of Macedonia, ſituated on a bay of the Archipelago, about 200 miles weſt of Conſtantinople: E. long. 25°, and N. lat. 41°.

CONTEXT, among divines and critics, that part of ſcripture or of a writing that precedes and follows the text.

CONTI, a town of Picardy in France, about fifteen miles ſouth-weſt of Amiens: E. long. 2° 20′, N. lat. 49° 40′.

CONTIGUITY, in geometry, is when the ſurface of one body touches that of another.

CONTINENT, in general, an appellation given to things continued without interruption; in which ſenſe we ſay, continent fever, *&c.*

CONTINENT, in geography, a great extent of land not interrupted by ſeas, in contradiſtinction to iſland and peninſula, *&c.* See GEOGRAPHY.

CONTINGENT, ſomething caſual or unuſual. Hence future contingent, denotes a conditional event which may or may not happen, according as circumſtances fall out.

CONTINGENTS are ſometimes uſed by mathematicians in the ſame ſenſe as tangent. See TANGENT.

CONTINUED *proportion*, in arithmetic, is that where the conſequent of the firſt ratio is the ſame with the antecedent of the ſecond; as 4 : 8 :: 8 : 16, in contradiſtinction to diſcrete proportion.

CONTINUITY, is defined by ſome ſchoolmen the immediate coheſion of parts in the ſame quantum; by others, a mode of body, whereby its extremities become one; and by others, a ſtate of body reſulting from the mutual implication of its parts. There are two kinds of continuity, mathematical and phyſical. The firſt is merely imaginary, ſince it ſuppoſes real or phyſical parts where there are none.

Phyſical continuity is that ſtate of two or more particles, in which their parts are ſo mutually implicated as to conſtitute one uninterrupted quantity or continuum.

CONTINUO, in muſic, ſignifies the thorough baſs, as baſſo continuo is the continual or thorough baſs, which is ſometimes marked in muſic books by the letters B. C.

CONTORSION, in medicine, has many ſignifications. 1. It denotes the iliac paſſion. 2. An incomplete diſlocation, when a bone is in part, but not entirely, forced from its articulation. 3. A diſlocation of the vertebræ of the back ſide-ways, or a crookedneſs of theſe vertebræ. And, 4. A diſorder of the head, in which it is drawn towards one ſide, either by a ſpaſmodic contraction of the muſcles on the ſame ſide, or a palſy of the antagoniſt muſcles on the other.

CONTOUR, in painting, the out-line, or that which defines a figure.

A great part of the ſkill of the painter lies in managing the contours well. Contour, with the Italian painters, ſignifies the lineaments of the face.

CONTOURNE, in heraldry, is uſed when a beaſt is repreſented ſtanding or running with its face to the ſiniſter ſide of the eſcutcheon, they being always ſuppoſed to look to the right, if not otherwiſe expreſſed.

CONTOURNIATED, a term among antiquaries applied to medals, the edges of which appear as if turned in a lath. This ſort of work ſeems to have had its origin in Greece, and to have been deſigned to perpetuate the memories of great men, particularly thoſe who had bore away the prize at the ſolemn games. Such

are

are thofe remaining of Homer, Solon, Euclid, Pythagoras, Socrates, and feveral athletæ.

CONTRABAND, in commerce, a prohibited commodity, or merchandife bought or fold, imported or exported, in prejudice to the laws and ordinances of a ftate, or the public prohibitions of the fovereign. Contraband goods are not only liable to confifcation themfelves, but alfo fubject all other allowed merchandife found with them in the fame box, bale or parcel, together with the horfes, waggons, *&c.* which conduct them. There are contrabands likewife, which, befides the forfeiture of the goods, are attended with feveral penalties and difabilities.

CONTRACT, in a general fenfe, a mutual confent of two or more parties, who voluntarily promife and oblige themfelves to do fomething, pay a certain fum, or the like. All donations, exchanges, leafes, *&c.* are fo many different contracts.

CONTRACTILE *force*, that property or power inherent in certain bodies, whereby, when extended, they are enabled to draw themfelves up again to their former dimenfions

CONTRACTION, in grammar, is the reducing of two fyllables into one, as *can't* for *cannot*, *fhould'ft* for *fhouldeft*, *&c.*

CONTRACTION, in phyfics. the diminifhing the extent or dimenfions of a body, or the caufing its parts to approach nearer to each other, in which fenfe it ftands oppofed to dilatation or expanfion.

CONTRA-FISSURE, in furgery, a kind of fracture, or fiffure, in the cranium, which fometimes happens on the fide oppofite to that which received the blow; or, at leaft, at fome diftance from it. See SURGERY.

CONTRARIETY, an oppofition between two things, which imports their being contrary to one another; and confifts in this, that one of the terms implies a negation of the other, either mediately or immediately; fo that contrariety may be faid to be the contraft, or oppofition of two things, one of which imports the abfence of the other, as love and hatred.

CONTRARY, a pofitive oppofite, which, fubfifting by turns in the fame fubject with its oppofite, is as remote from it as poffible, expells it, and is mutually expelled by it. Blacknefs and whitenefs, cold and heat, are fuch contraries.

CONTRAST. See RESEMBLANCE.

CONTRATE-*wheel*, in watch-work, that next to the crown, the teeth and hoop whereof lie contrary to thofe of the other wheels, from whence it takes its name. See WATCH-MAKING.

CONTRAVALLATION, or *the line* CONTRAVALLATION, in fortification, a trench guarded with a parapet, and ufually cut round about a place by the befiegers, to fecure themfelves on that fide, and to ftop the fallies of the garrifon. See FORTIFICATION.

CONTRAVENTION, in law, a man's failing to difcharge his word, obligation, duty, or the laws or cuftoms of the place.

CONTRAYERVA, in botany. See DORSTENIA.

CONTRE, in heraldry, an appellation given to feveral bearings, on account of their cutting the fhield contrary and oppofite ways: thus we meet with contre-bend, contre-chevron, contre-pale, *&c.* when there are two ordinaries of the fame nature oppofite to each other, fo as colour may be oppofed to metal, and metal to colour. See COUNTER.

CONTRITION, in theology, a forrow for our fins, refulting from the reflexion of having offended God, from the fole confideration of his goodnefs, without any regard to the punifhment due to the trefpafs, and attended with a fincere refolution of reforming them.

CONTROL is properly a double regifter kept of acts, iffues, *&c.* of the officers or commiffioners in the revenue, army, *&c.* in order to perceive the true ftate thereof, and to certify the truth, and the due keeping of the acts fubject to the enregifterment.

CONTROLLER, an officer appointed to control or overfee the accounts of other officers, and, on occafion, to certify whether or no things have been controlled or examined.

In Britain we have feveral officers of this name, as controller of the king's houfe, controller of the navy, controller of the cuftoms, controller of the mint, *&c.*

CONTROLLER *of the hanaper*, an officer that attends the lord chancellor daily, in term and in feal-time, to take all things fealed in leathern bags from the clerks of the hanaper, and to make the number and effect thereof, and enter them in a book, with all the duties belonging to the king and other officers for the fame, and fo charge the clerk of the hanaper with them.

CONTROLLER *of the pipe*, an officer of the exchequer, that makes out a fummons twice every year, to levy the farms and debts of the pipe. See PIPE, and EXCHEQUER.

CONTROLLERS *of the pells*, two officers of the exchequer, who are the chamberlain's clerks, and keep a control of the pell of receipts, and goings out.

CONTUSION, in medicine and furgery, any hurt of the body that is inflicted by a blunt inftrument. See SURGERY.

CONVALLARIA, or LILLY *of the* VALLEY, in botany, a genus of the hexandria monogynia clafs. The corolla is divided into fix fegments; and the berry is fpotted, and has three cells. The fpecies are eight, three of which are natives of Britain, *viz.* the majalis, or may-lily; the multiflora, or folomon's-feal; and the polygonatum, or fweet-fmelling folomon's-feal.

CONVENT, in church-hiftory. See MONASTERY.

CONVENTICLE, a private affembly or meeting, for the exercife of religion. The word was firft attributed as an appellation of reproach to the religious affemblies of Wickliffe, in this nation, in the reigns of Edward III. and Richard II. There were feveral ftatutes made in former reigns, for the fuppreffion of conventicles; but, by 1 William and Mary, it is ordered, that diffenters may affemble for the performance of religious worfhip, provided their doors be not locked, barred, or bolted.

CONVENTION, a treaty, contract, or agreement between two or more parties.

CONVENTION is alfo a name given to an extraordinary affembly of parliament, or the eftates of the realm, held without

without the king's writ; as was the convention of eſtates, who, upon the retreat of king James II. came to a concluſion that he had abdicated the throne, and that the right of ſucceſſion devolved to king William and queen Mary; whereupon their aſſembly expired as a convention, and was converted into a parliament.

CONVERGING, or CONVERGENT *lines*, in geometry, are ſuch as continually approach nearer one another, or whoſe diſtances become ſtill leſs and leſs. Theſe are oppoſed to divergent lines, the diſtances of which become continually greater: thoſe lines which converge one way, diverge the other.

CONVERGING *rays*, in optics, thoſe rays that, iſſuing from divers points of an object, incline towards another, till, at laſt, they meet and croſs, and then become diverging rays. See OPTICS.

CONVERSE, in mathematics. One propoſition is called the converſe of another, when, after a concluſion is drawn from ſomething ſuppoſed in the converſe propoſition, that concluſion is ſuppoſed; and then, that which in the other was ſuppoſed, is now drawn as a concluſion from it: thus, when two ſides of a triangle are equal, the angles under theſe ſides are equal; and, on the converſe, if theſe angles are equal, the two ſides are equal.

CONVERSION, in a moral ſenſe, implies a repentance for a temper and conduct unworthy our nature, and unbecoming our obligations to its Author, and a reſolution to act a wiſer and a better part for the future.

CONVERSION, in war, a military motion whereby the front of a battalion is turned where the flank was, in caſe the battalion is attacked in the flank.

CONVERSION *of equations*, in algebra. See Vol. I. p. 104.

CONVEX, an appellation given to the exterior ſurface of gibbous or globular bodies, in oppoſition to the hollow inner ſurface of ſuch bodies, which is called concave: thus we ſay, a convex frieze, lens, mirror, ſuperficies, *&c.*

CONVEXITY, that configuration or ſhape of a body, on account of which it is denominated convex.

CONVEYANCE, in law, a deed or inſtrument that paſſes land, *&c.* from one perſon to another.

CONVICT, in common law, a perſon that is found guilty of an offence by the verdict of a jury.

CONVICTION, in theology, expreſſes the firſt degree of repentance, wherein the ſinner becomes ſenſible of his guilt, of the evil nature of ſin, and of the danger of his own ways.

CONVOCATION, an aſſembly of the clergy of England, by their repreſentatives, to conſult of eccleſiaſtical matters. It is held during the ſeſſion of parliament, and conſiſts of an upper and a lower houſe. In the upper ſit the biſhops, and in the lower the inferior clergy, who are repreſented by their proctors, conſiſting of all the deans and archdeacons, of one proctor for every chapter, and two for the clergy of every dioceſe, in all one hundred and forty-three divines, *viz.* twenty-two deans, fifty-three archdeacons, twenty-four prebendaries, and forty-four proctors of the dioceſan clergy. The lower houſe chuſes its prolocutor, whoſe buſineſs it is to take care that the members attend, to collect their debates and votes, and to carry their reſolutions to the upper houſe. The convocation is ſummoned by the king's writ, directed to the archbiſhop of each province, requiring him to ſummon all biſhops, deans, archdeacons, *&c.*

The power of the convocation is limited by a ſtatute of Henry VIII. They are not to make any canons or eccleſiaſtical laws, without the king's licence; nor, when permitted to make any, can they put them in execution, but under ſeveral reſtrictions. They have the examining and cenſuring all heretical and ſchiſmatical books and perſons, *&c.* but there lies an appeal to the king in chancery, or to his delegates. The clergy in convocation, and their ſervants, have the ſame privileges as members of parliament.

CONVOLUTION, a winding motion, proper to the trunks of ſome plants, as the convolvulus, or bindweed; the claſpers of vines, bryony, *&c.*

CONVOLVULUS, or BIND-WEED, in botany, a genus of the pentandria monogynia claſs. The corolla is bell-ſhaped, and plaited; it has two ſtigmata; and the capſule is bilocular, each cell containing two ſeeds. There are forty-three ſpecies, only three of which are natives of Britain, *viz.* the arvenſis, or ſmall bindweed; the ſepium, or great bind-weed; and the ſoldanella, or ſea bind-weed.

CONVOY, in marine affairs, one or more ſhips of war, employed to accompany and protect merchant ſhips, and prevent their being inſulted by pirates, or the enemies of the ſtate in time of war.

CONVOY, in military matters, a body of men that guard any ſupply of men, money, ammunition, or proviſions, conveyed by land into a town, army, or the like, in time of war.

CONVULSION, in medicine, a preternatural and violent contraction of the membranous and muſcular parts of the body. See MEDICINE.

CONWAY, a market-town of Carnarvonſhire in North Wales, ſituated near the mouth of a river of the ſame name, fifteen miles weſt of St Aſaph: W. long. 3° 50′, and N. lat. 53° 20′.

CONYZA, or FLEA-BANE, in botany, a genus of the ſyngeneſia polygamia ſuperflua claſs. The receptacle is naked; the pappus is ſimple; the calix is roundiſh and imbricated; and the rays of the corolla are divided into three ſegments. There are nineteen ſpecies, only one of which is a native of Britain, *viz.* the ſquarroſa, or plowman's ſpikenard.

CONZA, a town of the kingdom of Naples in Italy, ſituated on the farther Principate, on the river Offanto, fifty miles ſouth-eaſt of the city of Naples: E. long. 16°, N. lat. 41°. It is the ſee of an archbiſhop.

COOPER, in geography, the name of a river in Carolina in North America.

COOPER, on board a ſhip, he that looks to the caſks, and all other veſſels for beer, water, or any other liquor. He has a mate under him.

CO-ORDINATE, ſomething of equal order, rank, or degree with another. See ORDER.

COPAIBA

COPAIBA, or *balsam of* Copaiba, a liquid resinous juice, flowing from incisions made in the trunk of the fera, a large tree which grows in the Spanish West Indies, and is used as a corroborating and detergent medicine.

COPAL, in the materia medica, a resin obtained from several sorts of large trees in New Spain. It is brought to us in irregular lumps; but it has never come into use as a medicine, and is rarely to be met with in the shops.

COPENHAGEN, the capital of the kingdom of Denmark, situated on the eastern shore of the island of Zealand, upon a fine bay of the Baltic sea, not far from the strait called the Sound: E. long. 13°, and N. lat. 55° 30′.

COPERNICAN, in general, something belonging to Copernicus. Hence,

Copernican *system* or *hypothesis*, that system of the world, wherein the sun is supposed to rest in the centre, and the planets, with the earth, to move in ellipses round him. See Vol. I. p. 434.

COPERNICUS, the name of an astronomical instrument, invented by Mr Whiston, to exhibit the motion and phænomena of the planets, both primary and secondary. It is built upon the Copernican system, and for that reason called by his name.

COPHTS, Cophti, or Copts, a name given to such of the Christians of Egypt as are of the sect of Jacobites.

The Cophts have a patriarch, who is styled the patriarch of Alexandria, having eleven or twelve bishops under him, but no archbishop. The rest of the clergy, whether secular or regular, are of the order of St Anthony, St Paul, and St Macarius, each of whom have their monasteries. The Cophts have seven sacraments, *viz.* baptism, the eucharist, confirmation, ordination, faith, fasting, and prayer.

COPHTIC, or Coptic *language*, is that spoke by the Cophts, being the ancient language of the Egyptians, intermixed with the Greek, and the characters of it being those of the Greek.

The ancient Coptic is now a dead language, to be met with no where but in books, and those only translations of the scriptures, and of ecclesiastical offices, or others that have a relation thereto; the language now used over all the country being that of the Arabic.

COPPEL, Copel, or Cuppel, a chemical vessel made of earth, pretty thick, and of the form of a platter or dish.

COPPELLING, or Cupelling, in chemistry, is the putting metallic substances into a coppel, or covered vessel, made of bone ashes, and set in a naked fire, to try what gold or silver they will afford. See p. 114.

COPPER constitutes a distinct genus of metals, being next to iron in specific gravity, but lighter than gold, silver, or lead. See p. 80.

COPPERAS, a name given to the factitious green vitriol. See Chemistry.

The English copperas is made at Deptford, in the following manner, from pyritæ. See Pyritæ.

A heap of these stones, two or three foot thick, is laid in a bed well rammed; where being turned once in six months, in five or six years, by the action of the air and rain, they begin to dissolve, and yield a liquor which is received in pits, and thence conveyed into a cistern, in a boiling-house. The liquor at length being pumped out of the cistern into a leaden boiler, and a quantity of iron added thereto, in two or three days the boiling is compleated; care having been taken all along to supply it with fresh quantities of iron, and to restore the boiling, whenever it seems to abate. When boiled sufficiently, it is drawn off into a cooler, with sticks across, where it is left 14 or 15 days to shoot. The uses of copperas are numerous. It is the chief ingredient in the dying of wool, cloths, and hats, black; in making ink, in tanning and dressing leather, *&c.* and from hence is prepared oil of vitriol, and a kind of Spanish brown for painters. In medicine it is rarely prescribed under the name of copperas, but it is a true salt of iron, and often prescribed under that name, and used instead of the genuine preparation; our chemists in general giving themselves no further trouble about the making of that salt, than to dissolve and purify the common copperas, and shoot it again into crystals.

COPPICE, or Copse, a little wood, consisting of under-woods, or such as may be raised either by sowing or planting.

COPULATION, the act of generation, or the congress of the male and female, otherwise called coition. See Generation.

COPY-HOLD, a tenure for which a tenant has nothing to shew but the copy of the rolls made by the steward of the lords court.

It is called a base tenure, because the tenant holds the land at the will of the lord. However, it is not simply at the will of the lord, but according to the custom of the manor by which such estate is descendible, and the tenants heirs may inherit it; and a copyholder, so long as he does his services, and does not break the custom, cannot be ejected by the lord; and if he be, he shall have trespass against him.

Copy-holder, one who is admitted tenant of lands or tenements within a manor, which time out of mind, by use and custom of the manor, have been demisable and demised to such as will take them in fee-simple or fee-tale, for life, years, or at will, according to the custom of the manor by copy of court-roll; but is generally where the tenant has such estate either in fee or for three lives.

COQUIMBO, a port-town of Chili, in South America, situated at the mouth of a river of the same name, which discharges itself into the pacific ocean: W. long 75° 10′, and N. lat. 30.°

COR caroli, in astronomy, an extraconstellated star in the northern hemisphere, situated between the coma berenices, and ursa major, so called by Dr Halley in honour of king Charles.

Cor hydræ, a fixed star of the first magnitude, in the constellation of hydra.

Cor leonis, or Regulus, in aſtronomy, a fixed ſtar of the firſt magnitude in the conſtellation leo.

CORACO-BRACHIALIS, in anatomy. See Vol. I. p. 196.

CORACOIDES, in anatomy. See Vol. I. p. 177.

CORACOMANTES, in antiquity, perſons who foretold events from their obſervations on crows.

CORACO-RADIALIS, in anatomy. See Vol. I. p. 197.

CORALLINA, or Coral, in zoology, a genus belonging to the order of vermes zoophyta. The trunk is radicated, jointed, and calcarious. The ſpecies are eight, diſtinguiſhed by the form of their branches, and are found in the ocean adhering to ſtones, bones, ſhells, *&c.* The corals were formerly believed to be vegetable ſubſtances hardened by the air; but are generally believed to be compoſed of a congeries of animals, which are even endued with the faculty of moving ſpontaneouſly. Linnæus's order of zoophyta is compoſed of animals of this kind, as the ſpongia, ſertularia, *&c.* See Natural History.

CORALLODENDRON, in botany. See Erythrina.

Coral *fiſhery*. Red coral is found in the Mediterranean, on the ſhores of Provence, from Cape de la Couronne to that of St Tropez; about the iſles of Majorca and Minorca; on the ſouth of Sicily; on the coaſts of Africa; and, laſtly, in the Ethiopic ocean, about cape Negro. The divers ſay, that the little branches are found only in the caverns whoſe ſituation is parallel to the earth's ſurface, and open to the ſouth. The manner of fiſhing being nearly the ſame wherever coral is found, it will ſuffice to inſtance the method uſed at the baſtion of France, under the direction of the company eſtabliſhed at Marſeilles for that fiſhery. Seven or eight men go in a boat commanded by the patron or proprietor, and when the net is thrown by the caſter, the reſt work the veſſel, and help to draw the net in. The net is compoſed of two rafters of wood tied croſs-wiſe, with leads fixed to them: to theſe they faſten a quantity of hemp twiſted looſely round, and intermingled with ſome large netting. This inſtrument is let down where they think there is coral, and pulled up again, when the coral is ſtrongly intangled in the hemp and netting. For this purpoſe, ſix boats are ſometimes required; and if in hauling in, the rope happens to break, the fiſhermen run the hazard of being loſt. Before the fiſhers go to ſee, they agree for the price of the coral, which is ſometimes more, ſometimes leſs a pound; and they engage, on pain of corporal puniſhment, that neither they nor their crew ſhall embezzle any, but deliver the whole to the proprietors. When the fiſhery is ended, which amounts one year with another to twenty-five quintals for each boat, it is divided into thirteen parts, of which the proprietor hath four, the caſters two, and the other ſix men one each, the thirteenth belongs to the company for payment of the boat furniſhed them.

CORAN, or Alcoran. See Alcoran.

CORAX, in ornithology, the trivial name of a ſpecies of corvus. See CORVUS.

CORBAN, a ſcripture term of an offering which had life, in oppoſition to the minchab which had no life.

Corban is alſo a ceremony which the Mahometans perform at the foot of mount Ararat, in Arabia, near Mecca. It conſiſts in killing a great number of ſheep, and diſtributing them among the poor.

CORBEILS, in fortification. See Basket.

CORBEL, in architecture, a repreſentation of a baſket, ſometimes ſeen on the heads of th caryatides.

CORBY, a town of Germany, thirty miles eaſt of Paderborn, in Weſtphalia: Eaſt long. 9° 20′, N. lat. 51° 40′.

CORCHORUS, Jews-sallad, in botany, a genus of the polyandria monogynia claſs. The corolla conſiſts of five petals; the calix is deciduous, and conſiſts of five leaves; and the capſule has many cells and valves. The ſpecies are ſix, none of them natives of Britain.

Cord *of wood*, a certain quantity of wood for burning, ſo called becauſe formerly meaſured with a cord. The dimenſions of a ſtatute cord of wood are eight feet long, four feet high, and four feet broad.

Cord-wood, is new wood, and ſuch as, when brought by water, comes on board a veſſel, in oppoſition to that which is floated.

CORDAGE, a term uſed, in general, for all ſorts of cord, whether ſmall, middling, or great. See Rope.

CORDATED, an appellation frequently given by naturaliſts to things ſomewhat reſembling a heart.

CORDED, in heraldry. A croſs corded ſome authors take for a croſs wound or wrenched about with cords. See Cabled-cross.

Others, with more probability, take it for a croſs made of two pieces of cord.

CORDELERAS, mountains of ſouth America, otherwiſe called Andes. See Andes.

CORDELIER, in church-hiſtory, a Franciſcan or religious of the order of St Francis.

CORDIA, in botany, a genus of the pentandria monogynia claſs. The corolla is tunnel-ſhaped, and has but one petal; the ſtylus is dichotomous; and the fruit is a bilocular drupa. The ſpecies are five, none of them natives of Britain.

CORDIAL, in medicine, whatever raiſes the ſpirits, and gives them a ſudden ſtrength and chearfulneſs, as wine, ſpirits, the effluvia of flowers, fruit, and many other ſubſtances.

CORDON, in fortification, a row of ſtones, made round on the outſide, and ſet between the wall of the fortreſs which lies aſlope, and the parapet which ſtands perpendicular, after ſuch a manner, that this difference may not be offenſive to the eye: whence the cordons ſerve only as an ornament, ranging round about the place, being only uſed in fortification of ſtone-work. For in thoſe made with earth, the void ſpace is filled up with pointed ſtakes.

CORDOUA, Cordova, a city of Andaluſia, in Spain,

ſituated on the river Guadalquivir, ſeventy-two miles north-eaſt of Seville, and ſeventy-five north of Malaga: W. long. 4° 45′, and N. lat. 37° 45′.

COREA, an iſland or peninſula on the north-eaſt coaſt of China, between 36° and 42° N. lat.

CORDWAINERS a term whereby ſhoemakers are denominated in ſtatutes. By a ſtatute of Jac. I. the maſter and wardens of the cordwainers company, *&c.* are to appoint ſearchers and triers of leather; and no leather is to be ſold before ſearched, ſealed, *&c.*

CORDYLINA, in botany. See YUCCA.

CORDYLUS, the trivial name of a ſpecies of Lacerta. See LACERTA.

COREGONUS, in ichthyology, a ſynonime of a ſpecies of Salmo. See SALMO.

COREIA, in antiquity, a feſtival in honour of Proſerpine.

COREOPSIS, in botany, a genus of the ſyngeneſia polygamia fruſtranea claſs. The receptacle is paleaceous, the pappus has two double horns; the calix is erect, and conſiſts of many leaves. There are eleven ſpecies, none of them natives of Britain.

CORFE-CASTLE, a borough-town of Dorſetſhire, about twelve miles eaſt of Dorcheſter, near the ſea: W. long. 2° 10′, and N. lat. 50° 36′. It ſends two members to Parliament.

CORFU, an iſland ſubject to the Venetians, ſituated in the Mediterranean, near the entrance of the gulph of Venice.

CORFU is alſo the capital of the above iſland: E. long. 20° 40′, and N. lat. 39° 40′

CORIA, a city of Eſtremadura, in Spain, thirty-five miles north of Alcantara: W. long 6° 40′, and N. lat. 39° 55′. It is a biſhop's ſee.

CORIANDRUM, in botany, a genus of the pentandria digynia claſs. The corolla is radiated; the involucrum univerſale conſiſts of one leaf, and the partiale is dimidiated; and the fruit is ſpherical. The ſpecies are two, only one of which, *viz.* the ſativum, or coriander, is a native of Britain. The ſeeds are uſed as a ſtomachic.

CORIARIA, MYRTLE-SUMACH, in botany, a genus of the diœcia decandria claſs. The calix of both male and female conſiſts of five leaves, and the corolla of each has five petals. The antheræ are divided into two parts: The female has five ſtyli, and five ſeeds. The ſpecies are two, none of them natives of Britain.

CORINDUM, in botany. See CARDIOSPERMUM.

CORINTH, a city of European Turky, ſituated near the iſthmus into the Morea, about fifty miles weſt of Athens, in 23° E. long. and 37° 30′ N. lat.

CORINTHIAN ORDER, in architecture. See Vol. I. p. 352.

CORIS, in botany, a genus of the pentandria monogynia claſs. The corolla has but one irregular leaf; the calix is prickly, and the capſule has five valves. There is but one ſpecies, a native of Montpelier.

CORISPERMUM, in botany, a genus of the monandria digynia claſs of plants, whoſe corolla conſiſts of two compreſſed, crooked, pointed petals, equal in ſize, and placed oppoſite one another: its fruit is a roundiſh capſule, compreſſed, bilocular, and having a furrowed edge; the ſeeds are of an oblong figure, and ſtand ſingle. There are two ſpecies, none of them natives of Britain.

CORK, or CORK-TREE, in botany. See QUERCUS.

CORK, or CORKING *of a ſaddle*, the pieces to which the bolſters are made faſt; ſo called as having formerly been made of cork.

CORK, in geography, the capital of a county of the ſame name, in Ireland, and province of Munſter, ſituated on the river Lee, about fifty miles ſouth of Limerick: W. long. 8° 25′, and N. lat. 51° 40′.

CORMANDEL-COAST, comprehends the eaſtern coaſt of the hither India, bounded by Golconda on the north, the bay of Bengal on the eaſt, Madura on the ſouth, and Biſnagar on the weſt: it lies between 10° and 20° N. lat.

CORMORANT, in ornithology. See TANTALUS.

CORN, in country affairs, the grain or ſeeds of plants, ſeparated from the ſpica, or ear, and uſed for making bread.

There are ſeveral ſpecies of corn, ſuch as wheat, rye and barley, millet and rice, oats, maize and lentils, peaſe, and a number of other kinds, each of which has its uſefulneſs and propriety. Corn is very different from fruits, with reſpect to the manner of its preſervation; and is capable of being preſerved in public granaries, for preſſing occaſions, and of being kept for ſeveral centuries.

The firſt method is to let it remain in the ſpike; the only expedient for conveying it to the iſlands and provinces of America. The inhabitants of thoſe countries ſave it in the ear, and raiſe it to maturity by that precaution: but this method of preſerving it, is attended with ſeveral inconveniencies among us; corn is apt to rot or ſprout, if any the leaſt moiſture is in the heap; the rats likewiſe infeſt it, and our want of ſtraw alſo obliges us to ſeparate the grain from the ear. The ſecond is to turn and winnow it frequently; or to pour it through a trough or mill-hopper, from one floor to another; being thus moved and aired every fifteen days, for the firſt ſix months, it will require leſs labour for the future, if lodged in a dry place: but if, through neglect, mites ſhould be allowed to ſlide into the heap, they will ſoon reduce the corn to a heap of duſt: this muſt be avoided by moving the corn anew, and rubbing the places adjacent with oils and herbs, whoſe ſtrong odour may chace them away; for which garlic and dwarf-elder are very effectual: they may likewiſe be expoſed to the open ſun, which immediately kills them. When the corn has been preſerved from all impurities for the ſpace of two years, and has exhaled all its fires, it may be kept for fifty or even a hundred years, by lodging it in pits, covered with ſtrong planks, cloſely joined together: but the ſafer way is to cover the heap with quick-lime, which ſhould be diſſolved by ſprinkling it over with a ſmall quantity of water; this cauſes the grains to ſhoot to the

the depth of two or three fingers, aud incloſes them with an incruſtation, through which neither air nor inſects can penetrate.

Corn not exceeding the under-mentioned prices have the following bounties *per* quarter, *viz.*

	Price *per* qr. l.	s.	Bounty *per* qr. s.	d.
Wheat	2	8	5	0
Rye	1	12	3	6
Barley and Malt	1	4	2	6
Oat-meal	0	15	2	6

In France corn of the growth of the kingdom is reckoned a contraband commodity.

CORN-MILL, a water-engine for grinding of corn. See MECHANICS.

CORN, in medicine and ſurgery, a hard tubercle like a flat wart, growing in ſeveral parts of the feet, eſpecially upon the joints of the toes. See MEDICINE.

CORNACHINE-*powder*, the ſame with what is ſometimes called the earl of Warwick's powder, and *pulvis de tribus*. It is prepared thus: Take four ounces of ſcammony; calcined hartſhorn prepared, three ounces; grind them together into a powder. It is given as a purge.

CORNAGE, an ancient tenure, the ſervice whereof was to blow a horn when any invaſion of the Scots was perceived.

This tenure was very frequent in the northern counties near the Picts wall.

CORNEA *tunica*, in anatomy. See Vol. I. p. 289.

CORNEL-*tree*, in botany. See CORNUS.

CORNELIAN. See CARNELIAN.

CORNER, in a general ſenſe, the ſame with angle. See ANGLE.

CORNET, in the military art of the ancients, an inſtrument much in the nature of a trumpet, which when it only ſounded, the enſigns were to march alone, without the ſoldiers; whereas, when the trumpet only ſounded, the ſoldiers were to move without the enſigns. The cornets and buccinæ ſounded the charge and retreat, and the cornets and trumpets ſounded during the courſe of the battle.

CORNET, in the military art of the moderns, the third commiſſion-officer in a troop of horſe or dragoons.

This is a very honourable poſt: he commands in the lieutenant's abſence; his principal duty being to carry the ſtandard, near the middle of the firſt rank of the ſquadron.

CORNEUS, the name by which Linnæus calls a kind of tin-ore, found in black columns, with irregular ſides, and terminating in priſms.

CORNICHE, CORNISH, or CORNICE, in architecture. See ARCHITECTURE.

CORNICHE is alſo uſed, in general, for all little projectures in maſonry or joinery, even where there are no columns, as the corniche of a chimney, beaufet, &c.

CORNICHE-*ring*, of a piece of ordnance, is that next from the muzzle-ring, backward.

CORNICULARIUS, in Roman antiquity, an officer of the army, appointed to aſſiſt the military tribune in quality of lieutenant.

CORNIX, in ornithology, the trivial name of a ſpecies of corvus. See CORVUS.

CORNU. See HORN.

CORNU *ammonis*, in natural hiſtory, foſſile ſhells, called alſo ſerpent-ſtones, or ſnake-ſtones.

They are found of all ſizes, from the breadth of a ſixpence, to more than two feet in diameter; ſome of them rounded, others greatly compreſſed, and lodged in different ſtrata of ſtones and clays; ſome again are ſmooth, and others ridged in different manners, their ſtriæ and ridges being either ſtraight, irregularly crooked, or undulated.

CORNU *cervi*. See HARTSHORN.

CORNUCOPIA, or HORN OF PLENTY, among painters, &c. is repreſented under the figure of a large horn, out of which iſſue fruits, flowers, &c. Upon medals the cornucopia is given to all deities, genii, and heroes, to mark the felicity and abundance of all the wealth procured by the goodneſs of the former, or the care and valour of the latter.

CORNUCOPIÆ, in botany, a genus of the triandria digynia claſs. The involucrum conſiſts of one tunnel-ſhaped crenated leaf, containing many flowers; and the calices are double-valved. There is but one ſpecies, *viz.* the cucullatum, a native of Smyrna.

CORNUS, or CORNEL-TREE, in botany, a genus of the tetrandria monogynia claſs. The involucrum conſiſts moſtly of four leaves; the petals are four, and above the fruit, which is a bilocular gluma. There are five ſpecies, none of them natives of Britain.

CORNUTIA, in botany, a genus of the didynamia angioſpermia claſs. The calix has five teeth; the ſtamina are longer than the corolla; the ſtylus is very long; and the berry contains but one ſeed.

CORNWAL, the moſt weſterly county of England, which gives the title of duke to the prince of Wales. It ſends forty-four members to parliament.

COROLLA, among botaniſts, the moſt conſpicuous part of a flower, ſurrounding the organs of generation, and compoſed of one or more flower-leaves, moſt commonly called petals, to diſtinguiſh them from the leaves of the plant; according as there is one, two, or three of theſe petals, the corolla is ſaid to be monopetalous, dipetalous, tripetalous, &c.

COROLLARY is a conſequence drawn from ſomething already advanced or demonſtrated.

COROLLULA, a term uſed by botaniſts, to expreſs the little partial flowers, which together make up the compound ones.

CORONA, among anatomiſts, denotes that edge of the glans penis where the preputium begins. See ANATOMY.

CORONA, among botaniſts. See PAPPUS.

CORONA BOREALIS, the NORTHERN CROWN, in aſtronomy. See Vol. I. p. 486.

CORONA *imperialis*, in zoology, a ſynonime of a ſpecies of conus. See CONUS.

CORONA *imperialis*, in botany. See FRITILLARIA.

CORONA

Corona *folis*, in botany. See Helianthus.

Coronæ *jus*. See Jus.

CORONAL, in anatomy. See Vol. I. p. 152.

CORONALE *os*, in anatomy, the fame with the os frontis. See Vol. I. p. 152.

CORONARIA, in botany. See Agrostema.

CORONARY *veffels*, in anatomy. See Anatomy, Part III. and IV.

CORONEOLA, in botany. See Lysimachia.

CORONER, an ancient officer of this kingdom, fo called becaufe he is wholly employed for the king and crown.

The office of coroners efpecially concerns the pleas of the crown; and they are confervators of the peace in the county where elected, being ufually two for each county. Their authority is judicial and minifterial: judicial, where a perfon comes to a violent death; to take and enter appeals of murder, pronounce judgment on outlawries, *&c.* and to inquire into the lands, goods, and efcape of murders, treafure trove, wreck of the fea, deodands, *&c.* The minifterial power is when coroners execute the king's writs, on exception taken to the fheriff, as being party in a fuit, of kin to either of the parties, or on the default of the fheriff, *&c.* The authority of the coroner does not terminate on the demife of the king, as that of judges, *&c.* does, who act by the king's commiffion. On default of fheriffs, coroners are to impannel juries, and to return iffues on juries not appearing, *&c.*

CORONET. See Crown.

Coronet, or Cronet *of a horfe*, the loweft part of the poftern, which runs round the coffin, and is diftinguifhed by the hair joining and covering the upper part of the hoof.

CORONILLA, in botany, a genus of the diadelphia decandria clafs. The calix is bilabiated, and the vexillum is hardly longer than the alæ. There are 11 fpecies, none of them natives of Britain.

CORONOPUS, in botany. See Plantago.

CORPORA *cavernofa*, in anatomy. See Vol. I. p. 272.

Corpora *olivaria*, in anatomy. See Vol. I. p. 287.

Corpora *pyramidalia*, in anatomy. See Vol. I. p. 287.

Corpora *ftriata*. in anatomy. See Vol. I. p. 286.

CORPORAL, an inferior officer under a ferjeant, in a company of foot, who has charge over one of the divifions, places and relieves centinels, and keeps good order in the corps de garde: he alfo receives the word from the inferior rounds, which paffes by his corps de garde. This officer carries a fufee, and is commonly an old foldier: there are generally three corporals in each company.

Corporal *of a fhip*, an officer who has the charge of fetting and relieving the watches and centries, and who fees that the foldiers and failors keep their arms neat and clean: he teaches them how to ufe their arms, and has a mate under him.

CORPORATION, a body politic, or incorporate, fo called, becaufe the perfons or members are joined into one body, and are qualified to take and grant, *&c.*

Corporations are either fpiritual or temporal: fpiritual, as bifhops, deans, archdeacons, parfons, vicars, *&c.* Temporal, as mayor, commonalty, bailiff, burgeffes, *&c.* And fome corporations are of a mixed nature, compofed of fpiritual and temporal perfons, fuch as heads of colleges and hofpitals, *&c.* All corporations are faid to be ecclefiaftical or lay: ecclefiaftical are either regular, as abbeys, priories, chapters, *&c.* or fecular, as bifhoprics, deanries, archdeaconries, *&c.* lay, as thofe of cities, towns, companies, or communities of commerce, *&c.*

CORPOREAL, thofe qualities which denominate a body. See Quality, Body, and Incorporeal.

CORPULENCY, in medicine, the ftate of a perfon too much loaded with flefh or fat.

CORPUS *callofum*, in anatomy. See Vol. I. p. 285.

Corpus *cavernofum*, in anatomy. See Vol. I. p. 272.

Corpus *reticulare*. See Reticulare.

Corpus *Chrifti*, a feftival of the church, kept on the next Thurfday after Trinity-funday, inftituted in honour of the euchariſt; to which alfo one of the colleges in Oxford is dedicated.

CORPUSCLE, in phyfics, a minute particle, or phyfical atom, being fuch as a natural body is made up of. By this word is not meant the elementary particles, nor the hypoftatical principles of chemifts; but fuch particles, whether of a fimple or compound nature, whofe parts will not be diffolved nor diffipated by ordinary degrees of heat.

CORPUSCULAR *philofophy*, that way of philofophifing which endeavours to explain things, and to account for the phenomena of nature by the motion, figure, reft, pofition, *&c.* of the corpufcles, or the minute particles of matter.

Mr Boyle fums up the chief principles of the corpufcular hypothefis, which now flourifhes under the mechanical philofophy, in thefe particulars:

1. They fuppofe that there is but one catholic or univerfal matter, which is an extended, impenetrable, and divifible fubftance, common to all bodies, and capable of all forms. 2. That this matter, in order to form the vaft variety of natural bodies, muft have motion in fome or all its affignable parts; and that this motion was given to matter by God the Creator of all things, and has all manner of directions and tendencies. 3. Matter muft alfo be actually divided into parts, and each of thefe primitive particles, fragments, or atoms of matter, muft have its proper magnitude or fize, as alfo its peculiar figure or fhape. 4. They fuppofe alfo, that thefe differently fized and fhaped particles may have as different orders and pofitions, whereof great variety may arife in the compofition of bodies.

CORRECTION, in printing, the pointing out or difcovering the faults in a printed fheet, in order to be amended by the compofitor before it be printed off. See Printing.

CORRECTOR, in general, denotes fomething that mends the faults or bad qualities of others.

Corrector *of the ftaple*, a clerk belonging to the ftaple, whofe bufinefs is to write down and record the bargains that merchants make there.

Corrector,

CORRECTOR, in medicine and pharmacy, an ingredient in a compofition, which guards againft or abates the force of another.

CORRELATIVE, fomething oppofed to another in a certain relation. Thus, father and fon are correlatives. Light and darknefs, motion and reft, are correlative and oppofite terms.

CORRIGIOLA, in botany. See ILLECEBRUM.

CORROBORANTS, or CORROBORATIVE *medicines*. See STRENGTHENERS.

CORROSION, in a general fenfe, the action of gnawing away, by degrees, the continuity of the parts of bodies.

CORROSION, in chemiftry, an action of bodies, by means of proper menftruums, that produces new combinations, and a change of their form, without converting them to fluidity. See CHEMISTRY.

CORRUGATOR, in anatomy. See Vol I. p. 291.

CORROSIVES, in furgery, are medicines which corrode whatever part of the body they are applied to: fuch are burnt alum, white precipitate of mercury, white vitriol, red precipitate of mercury, butter of antimony, lapis infernalis, *&c.*

CORRUPTION, the deftruction, extinction, or, at leaft, ceffation for a time, of the proper mode of exiftence of any natural body. See PUTREFACTION.

CORRUPTION *of blood*, in law, an infection accruing to a man's ftate, attainted of felony and treafon, and to his iffue; for as he lofes all to the prince, *&c.* his iffue cannot be heirs to him, or to any other anceftor by him: and if he were noble, his heirs are rendered ignoble.

CORSA, in architecture. See PLAT-*band*.

CORSAIR, a pirate, or perfon who fcours the fea for plunder, with an armed veffel, without commiffion from any prince or power. A corfair differs from a privateer, in that the latter acts under a commiffion, and only attacks the veffels of thofe at war with the ftate whence he had his commiffion.

CORSELET, a little cuirafs; or, according to others, an armour or coat made to cover the whole body, anciently worn by the pike-men, ufually placed in the front and flanks of the battle, for the better refifting the enemy's affaults, and guarding the foldiers placed behind them.

CORSICA, an ifland in the Mediterranean, between 8° and 10° E. long. and between 41° and 43° N. lat. about one hundred miles fouth of Genoa, and fubject to that republic; though the natives for many years difputed their right. This ifland is now in the hands of the French, after a glorious ftruggle for liberty under general Paoli.

CORTEX, or CORTEX *Peruvianus*. See CINCHONA.

CORTEX *cerebri*. See Vol. p. 285.

CORTONA, a city of Tufcany, in Italy, about thirty-five miles fouth-eaft of Sienna: E. long. 13°, and N. lat. 43° 15′.

CORTUSA, in botany, a genus of the pentandria monogynia clafs. The corolla is rotated, with an open limbus; and the capfule has two valves. There are two fpecies, none of them natives of Britain.

CORUNNA, or GROYNE, a port-town of Gallicia in Spain, fituated on a fine bay of the Atlantic ocean, about thirty-two miles north of Compoftella: W. long. 9°, and N. lat. 43°.

CORUS, in Jewifh antiquity. See HOMER.

CORUS, in our old writers, denotes eight bufhels, or a quarter.

CORUS is alfo a wind, fo called by the Jews, rifing in the fummer in the weft; and is that at prefent called the north-eaft-wind.

CORUSCATION, a glittering, or gleam of light iffuing from any thing It is chiefly ufed for a flafh of lightening darting from the clouds in time of thunder.

CORVUS, the RAVEN, or CROW-kind, in ornithology, a genus of birds, of the order of picæ, the diftinguifhing characteriftics of which are thefe: The beak is convex and cultrated; the noftrils are covered with briftly feathers; the tongue is forked and cartilaginous; and the feet are of the walking kind. The fpecies are nineteen, *viz.* 1. The hottentottus, is of a greenifh black colour, with long myftaches, and an equal tail. It is found at the Cape of Good Hope. 2. The corax, or raven of Englifh authors, is black, with a blueifh back, and a roundifh tail. It is a native of Europe, and feeds upon carrion: it is much given to theft, and may be taught to utter articulate founds. 3. The corone, or carrion-crow, is of a black blueifh colour, with the prime wing-feathers fharp, and a round tail: it lives upon carrion and fruits, and is a native of Europe. 4. The frugilegus, or rook, is black, with an afh-coloured forehead, and a roundifh tail. The rooks affemble in flocks, and infeft the corn-fields: many of them fleep together in the fame tree, by which means they are eafily taken. 5. The cornix, or royfton-crow, is afh-coloured, with the throat, wings, and tail black. It feeds upon worms, fnails, frogs, caterpillars, *&c.* 6. The monedula, or jack-daw, is of a dufky colour, with a hoary hind-head; and the wings, tail, and forehead black. It is a native of Europe. They flock together in winter, fleep, and build their nefts in old turrets and walls. 7. The glandularius, or jay, has blueifh wings, with tranfverfe black and white lines; and the body is variegated with an iron-colour. It is a native of Europe, and feeds upon nuts, corn, and fometimes fmall birds. 8. The criftatus, or blue-crefted jay, has the covert feathers of the wings marked with tranfverfe black lines, a blueifh body, and a black collar. It is a native of North America. 9. The cayanus, is of a violet colour above, and white below, with a black front and throat, and the point of the tail white: the feathers of the hind head are erect and rigid. It is a native of Cayenne. 10. The caryocatactes, is brown, and fpotted with white; the wings and tail are black; the prime tail-feathers are white at the points, but the intermediate ones have a worn appearance. It is a native of Europe, and feeds upon nuts. 11. The balicaffius is of a greenifh black colour, with a forked tail.

It is found on the Philippine iſles. 12. The afer, is of a violet blackiſh colour, and has a wedge-like tail. It is a native of Africa. 13. The pica, or magpye, is variegated with black and white, and its tail is ſhaped like a wedge. They build their neſts in trees in a very artificial manner; the outſide conſiſts of thorns both above and below, leaving only a hole for their entrance. They lay five or ſix eggs, which are pale and ſpotted: they feed upon ſmall birds, *&c.* and carefully lay up ſuperfluous food till they become hungry again. They may be learned to talk pretty diſtinctly. 14. The ſenegalenſis, is of a blackiſh violet colour, with black legs, and a wedge-ſhaped tail. It is a native of Senegal. 15. The brachyurus, is green below, with yellow lines on the head, and white ſpots on the wings. It is found in the Molucca iſles. 16. The canadenſis, is of a duſky colour, with a yellow forehead, and white below: it has a roundiſh tail, and is a native of Canada. 17. The pyrrhocorax, is blackiſh, with a yellow beak, and black legs. 18. The graculus, is of a blackiſh violet colour, with a yellow back and legs. 19. The eremita, is greeniſh, with a yellowiſh head, a ſmall creſt on the back part of the head, and a red beak and legs. The three laſt are natives of Switzerland.

CORVUS, the RAVEN, in aſtronomy. See Vol. I. p. 487.

CORVUS, in Roman antiquity, a military engine, or rather gallery, moveable at pleaſure by means of pullies, chiefly uſed in boarding the enemy's ſhips, to cover the men.

CORYBANTES, in antiquity, prieſts of the goddeſs Cybele, who, inſpired with a ſacred fury, danced up and down, toſſing their heads, and beating on cymbals or brazen drums. They inhabited mount Ida, in the iſland of Crete, where they nouriſhed the infant Jupiter, keeping a continual rattling with their cymbals, that his father Saturn, who had reſolved to devour all his male offspring, might not hear the child's cries.

CORYBANTICA, in Grecian antiquity, a feſtival kept in honour of the Corybantes.

CORYCOMACHIA, among the ancients, was a ſort of exerciſe in which they puſhed forwards a ball, ſuſpended from the ceiling, and at its return either caught it with their hands, or ſuffered it to meet their body. Oribaſius informs us it was recommended for extenuating too groſs bodies.

CORYDALIS, in botany. See FUMARIA.

CORYLUS, the HAZLE, in botany, a genus of the monoecia polyandria claſs. The calix of the male conſiſts of one trifid leaf, and contains but one flower; it has no corolla, but eight ſtamina: the calix of the female conſiſts of two lacerated leaves; it has no corolla; the ſtyli are two; and the nut is oval. There are two ſpecies, *viz.* the avellana, a native of Britain; and the colurna, a native of Bizantium.

CORYMBIUM, in botany, a genus of plants belonging to the ſyngeneſia monogynia claſs. The calix conſiſts of two leaves ſhaped like a priſm, and containing one flower; the corolla has but one regular petal; and the fruit contains one downy ſeed. There is but one ſpecies, a native of Africa.

CORYMBUS, in botany. See Vol. I. p. 637.

CORYPHA, in botany, a genus belonging to the order of palmæ flabellifoliæ. The corolla conſiſts of three petals; it has ſix ſtamina, and one piſtillum; and the fruit is a drupa containing one ſeed. There is but one ſpecies, a native of India.

CORYPHÆNA, in ichthyology, a genus belonging to the order of thoracici. The head is declined and truncated; the branchioſtege membrane has ſix rays; and the back fin runs the whole length of the back. There are twelve ſpecies, moſt of them found in foreign ſeas.

CORYZA, in medicine, a catarrh of the noſe. See CATARRH.

CORZOLA, or CURSCOLA, an iſland in the gulf of Venice, divided from Raguſa in Dalmatia, by a narrow ſtrait: E. long. 18°, and N. lat. 42° 35′.

COS, the WHET-STONE, in natural hiſtory, a genus of vitreſcent ſtones, conſiſting of fragments of an indeterminate figure, ſub-opaque, and granulated.

Of this genus there are ſeveral ſpecies, ſome conſiſting of rougher, and others of ſmoother, or even of altogether impalpable particles; and uſed not only for whet-ſtones, but alſo for mill-ſtones, and other the like purpoſes.

CO-SECANT, in geometry, the ſecant of an arch which is the complement of another to 90°. See GEOMETRY.

COSENZA, the capital of the hither Calabria, in the kingdom of Naples: E. long. 16° 35′, N. lat. 39° 15′. It is an archbiſhop's ſee.

CO-SINE, in trigonometry, the ſine of an arch, which is the complement of another to 90°. See GEOMETRY.

COSMETIC, in phyſic, any medicine or preparation which renders the ſkin ſoft and white, or helps to beautify and improve the complexion; as lip-ſalves, cold creams, ceruſs, *&c.*

COSMICAL, a term in aſtronomy, expreſſing one of the poetical riſings of a ſtar: thus a ſtar is ſaid to riſe coſmically, when it riſes with the ſun, or with that point of the ecliptic in which the ſun is at that time: and the coſmical ſetting is when a ſtar ſets in the weſt at the ſame time that the ſun riſes in the eaſt.

COSMOGRAPHY, a deſcription of the ſeveral parts of the viſible world; or the art of delineating the ſeveral bodies according to their magnitudes, motions, relations, *&c.*

Coſmography conſiſts of two parts, aſtronomy and geography. See ASTRONOMY, and GEOGRAPHY.

COSSACKS, people inhabiting the banks of the rivers Neiper and Don, near the Black-ſea and frontiers of Turky. Their country is commonly called the Ukraine, and is moſtly ſubject to Ruſſia.

COSSET, among farmers, a colt, calf, lamb, *&c.* brought up by hand, without the dam.

COSTAL, an appellation given by anatomiſts to ſeveral parts belonging to the ſides: thus we meet with coſtal muſcles, vertebræ, *&c.*

COSTA-RICA, a province of Mexico, bounded by the North ſea on the north-eaſt, and by the Pacific ocean on the ſouth-weſt. Its chief town is New-Carthage.

COSTARUM *depreſſores*, in anatomy. See Vol. I. p. 215.

COSTIVENESS, in medicine, a preternatural detention of the fæces, with an unuſual dryneſs and hardneſs thereof, and thence a ſuppreſſion of their evacuation. See Medicine.

COSTMARY, the Engliſh name of a ſpecies of tanzy. See Tanacetum.

COSTRANGULA, in botany. See Scrophularia.

COSTUME, a term among painters: thus a painter muſt obſerve the coſtume; that is, he muſt make every perſon and thing ſuſtain its proper character, and not only obſerve the ſtory, but the circumſtances, the ſcene of action, the country or place, and make the habits, arms, manners, proportions, and the like, to correſpond.

COSTUS, in botany, a genus of the monandria monogynia claſs. The interior part of the corolla is inflated and ringent; the inferior lip being trifid. There is but one ſpecies, *viz.* the arabicus, a native of both the Indies. The root of the coſtus is ſaid to attenuate acid humours, and to promote expectoration, perſpiration, and urine; but is now rarely to be met with in the ſhops.

CO-TANGENT, the tangent of an arch, which is the complement of another to 90°. See Geometry.

COTHURNIX, in ornithology. See Tetrao.

COTICE, or Cotise, in heraldry, is the fourth part of the bend; and with us ſeldom if ever borne but in couples, with a bend between them. See Bend.

The bend thus bordered, is ſaid to be cotiſed; as, he bears ſable, on a bend cotiſed argent, three cinquefoils. See Plate LXV. fig. 11.

COTINUS, in botany, the trivial name of a ſpecies of rhus. See Rhus.

COTONASTER, in botany. See Cratægus.

COTRONA, a town of the further Calabria, in the kingdom of Naples, ſituated on the Mediterranean, about fifteen miles ſouth-eaſt of St Severino: E. long. 17° 40′, and N. lat. 38° 50′. It is the ſee of a biſhop.

COTTON, in commerce, a ſoft downy ſubſtance found on the bombax, or cotton-tree. See Bombax.

Cotton is ſeparated from the ſeeds of the plant by a mill, and then ſpun and prepared for all ſorts of fine works, as ſtockings, waiſtcoats, quilts, tapeſtry, curtains, *&c.* With it they likewiſe make muſlin, and ſometimes it is mixed with wool, ſometimes with ſilk, and even with gold itſelf.

The fineſt ſort comes from Bengal and the coaſt of Coromandel.

Cotton makes a very conſiderable article in commerce, and is diſtinguiſhed into cotton-wool, and cotton-thread. The firſt is brought moſtly from Cyprus, St John d'Acre, and Smyrna: the moſt eſteemed is white, long, and ſoft. Thoſe who buy it in bales ſhould ſee that it has not been wet, moiſture being very prejudicial to it. The price of the fineſt is uſually from ſix to ſeven piaſters the quintal of forty-four ocos.

Of cotton thread, that of Damas, called cotton d'ounce, and that of Jeruſalem, called bazas, are the moſt eſteemed; as alſo that of the Antilles iſlands. It is to be choſen white, fine, very dry, and evenly ſpun. The other cotton-threads are the half bazas, the rames, the beledin, and gondezel; the payas and montaſiri, the geneguins, the baquins, the joſſelaſſars, of which there are two ſorts. Thoſe of India, known by the name of Tutucorin, Java, Bengal, and Surat, are of four or five ſorts, diſtinguiſhed by the letters A, B, C, *&c.* They are ſold in bags, with a deduction of one pound and a half on each of thoſe of Tutucorin, which are the deareſt, and two pounds on each bag of the other ſorts. For thoſe of Fielebas, Smyrna, Aleppo, and Jeruſalem, the deduction at Amſterdam is eight in the hundred for the tare, and two in the hundred for weight, and on the value one *per cent.* for prompt payment.

Cotton of Siam, is a kind of ſilky cotton in the Antilles, ſo called becauſe the grain was brought from Siam. It is of an extraordinary fineneſs, even ſurpaſſing ſilk in ſoftneſs. They make hoſe of it there preferable to ſilk ones, for their luſtre and beauty. They ſell from ten to twelve and fifteen crowns a pair, but there are very few made, unleſs for curioſity.

The manner of packing Cotton, *as practiſed in the Antilles.* The bags are made of coarſe cloth, of which they take three ells and a half each: the breadth is one ell three inches. When the bag has been well ſoaked in water, they hang it up, extending the mouth of it to croſs pieces of timber nailed to poſts fixed in the ground ſeven or eight feet high. He who packs it goes into the bag, which is ſix feet nine inches deep, or thereabouts, and preſſes down the cotton, which another hands him, with hands and feet; obſerving to tread it equally every where, and putting in but little at a time. The beſt time of packing is in rainy moiſt weather, provided the cotton be under cover. The bag ſhould contain from 300 to 320 pounds. The tare abated in the Antilles is three in the hundred. Cotton being a production applicable to a great variety of manufactures, it cannot be too much cultivated in our own plantations that will admit of it.

Cotton wool, not of the Britiſh plantations, pays on importation $\frac{77}{100}$d. the pound, and draws back on exportation $\frac{67\frac{1}{2}}{100}$d. Cotton yarn the pound, not of the Eaſt Indies, pays $2\frac{87\frac{1}{4}}{100}$d. and draws back $2\frac{58\frac{3}{4}}{100}$d. Cotton yarn the pound of the Eaſt Indies pays $4\frac{56}{100}$d. and draws back $4\frac{27}{100}$d.

Lavender Cotton. See Santolina.

Philoſophic Cotton, a name given to the flowers of zinc, on account of their white colour, and reſemblance to cotton.

Cotton-weed. See Gnaphalium.

COTTUS, in ichthyology, a genus belonging to the order of thoracici. The head is broader than the body, and the gill-membrane has ſix rays. There are

fix ſpecies, *viz*. the cataphractus, quadricornis, grunniens, ſcaber, ſcorpius, and gobio.

COTULA, in botany, a genus of the ſyngcneſia polygamia ſuperflua claſs. The receptacle is naked; the pappus is marginated; and the corollulæ of the diſk are divided into four ſegments; the ſpecies are ſix, none of them natives of Britain.

COTULA, or COTYLA, in antiquity, a liquid meaſure among the Greeks, equal to the hemina of the Romans, containing half a ſextary, or four acetabula: hence it appears that it contained ten ounces of wine, and nine of oil.

COTURNIX, in ornithology. See TETRAO.

COTYLEDON, in botany, a genus of the decandria pentagynia claſs. The calix is divided into five ſegments; the corolla conſiſts of one petal; there are five nectariferous ſcales at the baſe of the germen: and it has five capſules. The ſpecies are eight, only one of which is a native of Britain, *viz*. the umbilicus, or navel-wort.

COTYLEDONES, in anatomy, are certain glandular bodies, adhering to the chorion of ſome animals.

COUGH, in medicine. See MEDICINE.

COUGH, in painting, a term uſed for each lay or impreſſion of colour, either in oil or water, wherewith the painter covers his canvas, wall, wainſcot, or other matter to be painted.

COUGH-GRASS, in botany. See TRITICUM.

COUCHANT, in heraldry, is underſtood of a lion, or other beaſt, when lying down, but with his head raiſed, which diſtinguiſhes the poſture of couchant from dormant, wherein he is ſuppoſed quite ſtretched out and aſleep. See Plate LXV. fig. 9.

COUCHE', in heraldry, denotes any thing lying along: thus, chevron couché, is a chevron lying ſideways, with the two ends on each ſide of the ſhield, which ſhould properly reſt on the baſe.

COUCHING *of a cataract*, in ſurgery. See SURGERY.

COVENANT, a contract or agreement, made between two or more perſons, to perform ſomething.

COVENTRY, a city and biſhop's fee in Warwickſhire, ſituated 80 miles north weſt of London, and 10 miles north of Warwick: W. long. 1° 26′, and N. lat. 52° 25′.

COVENTRY-BELLS, in botany. See CAMPANULA.

COVERDEN, a town of the united provinces, ſituated in that of Overyſſel, near the confines of Weſtphalia: E. long. 6° 45′, and N lat. 52° 50′.

CO-VERSED SINE, in geometry, the remaining part of the diameter of a circle, after the verſed ſine is taken from it. See GEOMETRY.

COVERT WAY, or CORRIDOR, in fortification, a ſpace of ground, level with the field on the edge of the ditch, three or four fathoms broad, ranging quite round the half moons, and other works toward the the country. It has a parapet raiſed on a level, together with its banquets and glacis. See FORTIFICATION.

COVERTURE, in law, is applied to the ſtate and condition of a married woman, who is under the power of her huſband, and therefore called *femme couvert*.

COVING, in building, is when houſes are built projecting over the ground plot, and the turned projecture arched with timber, lathed and plaiſtered.

COULTER, in huſbandry, an iron-inſtrument, fixed in the beam of a plough, and ſerving to cut the edge of each furrow. See AGRICULTURE.

COUNCIL, or COUNSEL, in a general ſenſe, an aſſembly of divers conſiderable perſons to concert meaſures relating to the ſtate.

Aulic COUNCIL. See AULIC.

Cabinet COUNCIL. See PRIVY-COUNCIL.

Common COUNCIL, in the city of London, is a court wherein are made all bye-laws which bind the citizens. It conſiſts, like the parliament, of two houſes; an upper, compoſed of the lord mayor and aldermen; and a lower, of a number of common-council-men, choſen by the ſeveral wards, as repreſentatives of the body of the citizens.

Privy COUNCIL, the *primum mobile* of the civil government of Great Britain, bearing part of that great weight in the government which otherwiſe would be too heavy upon the king.

It is compoſed of eminent perſons, the number of whom is at the ſovereign's pleaſure, who are bound by oath to adviſe the king to the beſt of their judgment, with all the fidelity and ſecrecy that becomes their ſtation. The king may declare to, or conceal from, his privy-council whatever he thinks fit; and has a ſelect council out of their number, commonly called the *cabinet council*, with whom his majeſty determines ſuch matters as are moſt important, and requires the utmoſt ſecrecy.

Privy-counſellors, though but gentlemen, have precedence of all the knights and younger ſons of barons and viſcounts, and are ſtyled right honourable.

COUNCIL *of war*, an aſſembly of the principal officers of an army or fleet, occaſionally called by the general or admiral to concert meaſures for their conduct with regard to ſieges, retreats, engagements, *&c*.

COUNCIL, in church hiſtory, an aſſembly of prelates and doctors, met for the regulating matters relating to the doctrine or diſcipline of the church.

National COUNCIL, is an aſſembly of prelates of a nation under their primate or patriarch.

Oecumenical or general COUNCIL, is an aſſembly which repreſents the whole body of the univerſal church. The Romaniſts reckon eighteeen of them; Bullinger, in his treatiſe de Conciliis, ſix; Dr Prideaux, ſeven; and biſhop Beveridge has increaſed the number to eight, which, he ſays, are all the general councils which have ever been held ſince the time of the firſt Chriſtian emperor. They are as follows: 1. The council of Nice, held in the reign of Conſtantine the Great, on account of the hereſy of Arius. 2. The council of Conſtantinople, called under the reign and by the command of Theodoſius the Great, for much the ſame end that the former council was ſummoned. 3. The council of Epheſus, convened by Theodoſius the younger, at the ſuit of Neſtorius. 4. The council of Calcedon, held in the reign of Martianus, which approved of the Eutychian hereſy. 5. The ſecond council of Conſtantinople, aſſembled by the emperor

Juſtinian,

Justinian, condemned the three chapters taken out of the book of Theodorus of Mopsuestia, having first decided that it was lawful to anathematize the dead. Some authors tell us, that they likewise condemned the several errors of Origen about the Trinity, the plurality of worlds, and pre-existence of souls. 6. The third council of Constantinople, held by the command of Constantinus Pogonatus the emperor, in which they received the definitions of the five first general councils, and particularly that against Origen and Theodorus of Mopsuestia. 7. The second Nicene council. 8. The fourth council of Constantinople, assembled when Lewis II. was emperor of the west. The regulations which they made are contained in twenty-seven canons, the heads of which are set down by M. du Pin, to whom the reader is referred.

COUNSELLOR, in general, a person who advises another: thus we say, a counsellor at law, a privy counsellor, *&c.*

Counsellor *at law*, a person retained by a client to plead his cause in a public court of judicature.

COUNT, a nobleman who possesses a domain erected into a county. The dignity is a medium between that of a duke and a baron.

Counts were originally lords of the court, or of the emperor's retinue, and had their name comites *a comitando*.

Count-wheel, in the striking part of a clock, a wheel which moves round once in twelve or twenty-four hours. It is sometimes called the locking wheel.

COUNTER, a term which enters into the composition of diverse words of our language, and generally implies opposition; but when applied to deeds, means an exact copy kept of the contrary party, and sometimes signed by both parties.

Counter alley, in gardening. See Alley.

Counter approaches, in fortification, lines and trenches made by the besieged in order to attack the works of the besiegers, or to hinder their approaches.

Counter barry, or Contre barre', in heraldry, is the same as our bendy sinister *per* bend counterchanged. See Barry.

Counter battery, is a battery raised to play upon another to dismount the guns.

Counter-changed, in heraldry, is when any field or charge is divided or parted by any line or lines of partition, consisting all interchangeably of the same tinctures. See plate LXV. fig. 12.

Counter-charge, a reciprocal charge or recrimination brought against an accuser.

Counter-chevroned, a chield chevrony, parted by one or more partition lines.

Counter-componed, in heraldry, is when the figure is compounded of two panes, as in Plate LXV. fig. 13.

Counter-drawing, in painting, is the copying a design, or painting, by means of a fine linen-cloth, an oiled paper, or other transparent matter, where the strokes appearing through are followed with a pencil, with or without colour. Sometimes it is done on glass, and with frames or nets divided into squares with silk or with thread, and also by means of instruments invented for the purpose, as the parallelogram.

Counter-ermine, in heraldry, is the contrary of ermine, being a black field with white spots. See Plate LXV. fig. 14.

Counterfeits, in law, are persons that obtain any money or goods by counterfeit letters or false tokens, who being convicted before justices of assize or of the peace, *&c.* are to suffer such punishment as shall be thought fit to be inflicted under death, as imprisonment, pillory, *&c.*

Counter-faced, or Conter-face', in heraldry, is the same that we call barry *per* pale counterchanged; but then the number of panes into which the field is divided is always specified. See Barry.

Counter-foil, or Counter-stock, in the exchequer, that part of a tally which is kept by an officer of the court.

Counter-forts, spurs or buttresses serving as props to a wall subject to bulge or be thrown down.

Counter-fugue, in music, is when the fugues go contrary to one another. See Fugue.

Counter guard, in fortification, is a work raised before the point of a bastion, consisting of two long faces parallel to the faces of the bastion, making a salliant angle: they are sometimes of other shapes, or otherwise situated.

Counter-light, or Conter-jour, a light opposite to any thing, which makes it appear to disadvantage. A single counter-light is sufficient to take away all the beauty of a fine painting.

Counter-*march*, in military affairs, a change of the face or wings of a battalion, by which means those that were in the front come to be in the rear.

It also signifies returning, or marching back again.

Counter-mine, in war, a well and gallery drove and sunk till it meet the enemy's mine, to prevent its effect.

Counter-paled, *contre pale*, in heraldry, is when the escutcheon is divided into twelve pales parted per fesse, the two colours being counter-changed; so that the upper are of one colour, and the lower of another.

Counter-part, in music, denotes one part to be applied to another. Thus the bass is said to be a counter-part to the treble.

Counter-passant, is when two lions are in a coat of arms, and the one seems to go quite the contrary way from the other.

Counter-point, in music, the art of composing harmony, or of disposing several parts in such a manner as to make an agreeable whole or a concert.

Counter-pointed, *contre pointé*, in heraldry, is when two chevrons in one escutcheon meet in the points, the one rising as usual from the base, and the other inverted falling from the chief; so that they are counter to one another in the points. They may also be counter-pointed when they are founded upon the sides of the shield, and the points meet that way, called counter-pointed in fesse.

COUNTER-POTENT, *contre-potencé*, in heraldry, is reckoned a fur as well as vair and ermine, but composed of such pieces as represent the tops of crutches, called in French *potences*, and in old English *potents*.

COUNTER-PROOF, in rolling-press printing, a print taken off from another fresh printed; which by being passed through the press, gives the figure of the former, but inverted. To counter-prove, is also to pass a design in black lead, or red chalk, through the press, after having moistened with a spunge both that and the paper on which the counter-proof is to be taken.

COUNTER-QUARTERED, *contre-ecartelé*, in heraldry, denotes the escutcheon, after being quartered, to have each quarter again divided into two.

COUNTER-SALIENT, is when two beasts are borne in a coat leaping from each other directly the contrary way.

COUNTER-SCARP, in fortification, is properly the exterior talus or slop of the ditch; but it is often taken for the covered way and the glacis. In this sense we say, the enemy have lodged themselves on the counter-scarp.

Angle of the COUNTER-SCARP, is that made by the two sides of the counter-scarp meeting before the middle of the curtin.

COUNTER-SIGNING, the signing the writing of a superior in quality of secretary. Thus charters are signed by the king, and counter-signed by a secretary of state or lord chancellor.

COUNTER-SWALLOW-TAIL, in fortification, an outwork in form of a single tenaille, wider at the gorge than the head.

COUNTER-TENOR, called by the French *haut contre*, one of the middle parts of music opposite to the tenor. See TENOR.

COUNTER-TIME, in the menage, is the defence or resistance of a horse that interrupts his cadence, and the measure of his menage, occasioned either by a bad horseman, or by the malice of the horse.

COUNTER is also the name of a counting-board in a shop, and of a piece of metal with a stamp on it, used in playing at cards.

COUNTER *of a horse*, that part of a horse's forehand which lies between the shoulders and under the neck.

COUNTERS *in a ship*, are two. 1. The hollow arching from the gallery to the lower part of the straight piece of the stern, is called the upper counter. 2. The lower counter is between the transom and the lower part of the gallery.

COUNTER is also the name of two prisons in the city of London, *viz*. the Poultry and Woodstreet.

COUNTING. See ACCOUNTING.

COUNTY, in geography, originally signified the territory of a count or earl, but now it is used in the same sense with shire. See SHIRE.

COUNTY-COURT, a court of justice, held every month in each county, by the sheriff or his deputy.

COUPED, in heraldry, is used to express the head, or any limb, of an animal, cut off from the trunk, smooth; distinguishing it from that which is called erased, that is, forcibly torn off, and therefore is ragged and uneven.

COUPED is also used to signify such crosses, bars, bends, chevrons, *&c*. as do not touch the sides of the escutcheons, but are, as it were, cut off from them.

COUPER, the name of two towns of Scotland, the one situated about twelve miles north-east of Perth, in the shire of Angus, W. long. 3°, and N. lat. 56° 30′; and the other in the county of Fife, about ten miles west of St Andrews: W. long. 2° 40′, and N. lat. 56° 20′.

COUPLE-CLOSS, in heraldry, the fourth part of a chevron, never borne but in pairs, except there be a chevron between them, saith Guillim, though Bloom gives an instance to the contrary.

COUPLET, a division of a hymn, ode, song, *&c*. wherein an equal number, or equal measure of verses is found in each part; which divisions, in odes, are called strophes.

COURBARIL, in botany. See HYMENÆA.

COURIER, a messenger sent post, or express, to carry dispatches.

COURLAND, a dutchy situated between 21° and 26° of E. long. and between 56° 30′, and 57° 30′ N. lat. It is bounded by the river Dwina, which divides it from Livonia, on the north; by Lithuania, on the east; by Samogitia, on the south; and by the Baltic sea on the west; being 130 miles long, and 30 broad.

COURSING, among sportsmen, is of three sorts, *viz*. at the deer, at the hare, and at the fox. These coursings are with greyhounds; for the deer there are two sorts of coursings, the one with the paddock, the other either in the forest or purlieu. See PADDOCK, *&c*.

In coursing the hare, the best way is to find one sitting, and when she is first started, to give her ground, or law, which is generally twelve-score yards. In coursing a fox, you are to stand close, and on a clear wind.

COURT, in a law sense, the place where judges distribute justice, or exercise jurisdiction: also the assembly of judges, jury, *&c*. in that place.

Courts are divided into superior and inferior, and into courts of record and base courts: again, courts are either such as are held in the king's name, as all the ordinary courts; or where the precepts are issued in the name of the judge, as the admiral's court.

The superior courts are those of the king's-bench, the common-pleas, the exchequer, and the court of chancery. See KING'S-BENCH, COMMON-PLEAS, EXCHEQUER, and CHANCERY.

A court of record is that which has a power to hold plea, according to the course of the common law, of real, personal, and mixt actions; where the debt or damage is forty shillings, or above, as the court of King's Bench, *&c*.

COURT *of admiralty*. See ADMIRALTY.

COURT *of arches*. See ARCHES.

COURT-BARON, a court that every lord of a manor has within his own precincts. This court must be held by

by prescription, and is of two kinds, *viz.* by common law, and by custom: the former is where the barons or freeholders, being suitors, are the judges; the other is that where the lord, or his steward, is the judge.

COURT *of chivalry*, or *the marshal's* COURT, that whereof the judges are the lord high constable, and the earl marshal of England.

This court is the fountain of martial law; and the earl marshal is not only one of the judges, but is to see execution done.

COURT *of conscience*, a court in the cities of London, Westminster, and some other places, that determines matters in all cases where the debt or damage is under forty shillings.

COURT *of delegates*, a court where delegates are appointed by the king's commission, under the great seal, upon an appeal to him from the sentence of an archbishop, *&c.* in ecclesiastical causes; or of the court of admiralty, in any marine cause.

COURT *of hustings*, a court of record held at Guildhall, for the city of London, before the lord mayor and aldermen, sheriffs and recorder, where all pleas, real, personal, and mixt, are determined; where all lands, tenements, *&c.* within the said city, or its bounds, are pleadable in two hustings; the one called the hustings of plea of lands, and the other the hustings of common pleas. The court of hustings is the highest court within the city, in which writs of exigent may be taken out, and outlawries awarded, wherein judgment is given by the recorder.

There are also other courts called wardmotes, or meeting of the wards; and courts of holymote, or assemblies of the guilds and fraternities.

COURT LEET, a court ordained for the punishment of offences under high treason against the crown.

COURT-MARTIAL, a court appointed for the punishing offences in officers, soldiers, and sailors, the powers of which are regulated by the mutiny-bill.

COURT *of requests*, was a court of equity, of the same nature with the chancery, but inferior to it.

COURTESY, or CURTESY *of England*, a certain tenure whereby a man marrying an heiress seized of lands of fee simple, or fee tail general, or seized as heir of the tail special, and getteth a child by her that cometh alive into the world, though both it and his wife die forthwith; yet, if she were in possession, he shall keep the land during his life, and is called *tenant per legem Angliæ*, or tenant by the courtesy of England; because this privilege is not allowed in any country except Scotland, where it is called *curialitas Scotiæ*.

COURTISAN, a woman who prostitutes herself for hire, especially to people of superior rank.

COURTRAY, a town of the Austrian Netherlands, situated on the river Lys, about twenty-three miles south-west of Ghent, and fourteen east of Ypres: E. long. 3° 10′, and N. lat. 50° 48′.

COUSIN, a term of relation between the children of brothers and sisters, who in the first generation are called cousin-germans, in the second generation second cousins, *&c.* If sprung from the relations of the father's side, they are denominated paternal cousins; if on the mother's, maternal.

COUSU, in heraldry, signifies a piece of another colour or metal placed on the ordinary, as if it were sewed on, as the word imports. This is generally of colour upon colour, or metal upon metal, contrary to the general rule of heraldry.

COVERT, in heraldry, denotes something like a piece of hanging, or a pavillion falling over the top of a chief or other ordinary, so as not to hide, but only to be a covering to it.

COW, in zoology. See BOS.

Sea-COW, in zoology. See TRICHECUS.

COW-ITCH, in botany. See PHASEOLUS.

COW'S-LIP, in botany. See PRIMULA.

COW'S-LIP *of Jerusalem* See PULMONARIA.

COWARD, in heraldry, a term given to a lion borne in an escutcheon with his tail doubled or turned in between his legs.

COWES, a town and harbour on the northern coast of the isle of Wight, situated about eight miles south of Plymouth: W. long. 1° 25′, and N. lat. 50° 45′.

COWL, or COUL, a habit worn by the Bernardines and Benedictines, of which there are two kinds; one white, very large, worn in ceremonies; the other black, worn on ordinary occasions, in the streets, *&c.*

Friar's COWL, in botany. See ARISARUM.

COXWOLD, a market-town in the north riding of Yorkshire, about fourteen miles north of the city of York: W. long. 50′, and N. lat. 54° 20′.

COZUMEL, an island near the western coast of Jucatan, where Cortez landed and refreshed his troops, before entering upon the conquest of Mexico: W. long. 89°, and N. lat. 13°.

CRAB, in zoology. See CANCER.

CRAB'S CLAWS, in the materia medica, are the tips of the claws of the common crab broken off at the verge of the black part, so much of the extremity of the claws only being allowed to be used in medicine as is tinged with this colour. The blackness, however, is only superficial; they are of a greyish white within, and when levigated furnish a tolerable white powder.

Crab's claws are of the number of the alkaline absorbents, but they are superior to the generality of them in some degree, as they are found on a chemical analysis to contain a volatile urinous salt.

CRAB'S EYES, in pharmacy, are a strong concretion in the head of the cray-fish. They are rounded on one side, and depressed and sinuated on the other, considerably heavy, moderately hard, and without smell. We have them from Holland, Muscovy, Poland, Denmark, Sweden, and many other places.

Crab's eyes are much used both in the shop medicines and extemporaneous prescriptions, being accounted not only absorbent and drying, but also discussive and diuretic.

CRAB, an engine of wood, with three claws, placed on the ground like a capstan, and used at launching or heaving ships into the dock.

CRABRO,

CRABRO, in zoology, See TENTHREDO.

CRACOA, in botany. See VICIA.

CRACKER, in ornithology, See ANAS.

CRACOW, by ſome accounted the capital city of Poland, is ſituated in the province of little Poland, and palatinate of Cracow, in a fine plane near the banks of the Viſtula. It has an univerſity, and is the ſee of a biſhop, and the ſeat of the ſupreme courts of juſtice: it ſtands about 140 miles ſouth-weſt of Warſaw, in 19° 30′ of E. long. and 50° N. lat.

CRADLE, a well known machine in which infants are rocked to ſleep.

It denotes alſo that part of the ſtock of a croſs bow where the bullet is put.

CRADLE, in ſurgery, a caſe in which a broken leg is laid after being ſet.

CRADLE, among ſhipwrights, a timber frame made along the outſide of a ſhip by the bilge, for the convenience of launching her with eaſe and ſafety.

CRAFT, in the ſea language, ſignifies all manner of nets, lines, hooks, *&c.* uſed in fiſhing. Hence all ſuch little veſſels as ketches, hoys, and ſmacks, *&c.* uſed in the fiſhing trade, are called ſmall craft.

CRAIL, or CAREIL, a parliament town of Scotland, ſituated on the ſea-coaſt of the county of Fife, about ſeven miles ſouth-eaſt of St Andrews: W. long. 2° 20′ and N. lat. 56° 17′.

CRAMBE, *wild* SEA-CABBAGE, in botany, a genus of the tetradynamia ſiliquoſa claſs. The four long filaments are forked at the points, and the antheræ are fixed upon one of them; the berry is dry, globular, and deciduous. The ſpecies are three, only one of which, *viz.* the maritima, or ſea-colewort, is a native of Britain.

CRAMP, in medicine, a convulſive contraction of a muſcular part of the body.

CRAMP FISH. See TORPEDO.

CRAMP IRON, or CRAMPS, a piece of iron bent at each end, which ſerves to faſten together pieces of wood, ſtones, or other things.

CRAMPER, in ichthyology. See CYPRINUS.

CRAMPONE'E, in heraldry, an epithet given to a croſs which has at each end a cramp or ſquare piece coming from it; that from the arm in chief towards the ſiniſter angle, that from the arm on that ſide downwards, that from the arm in baſe towards the dexter ſide, and that from the dexter arm upwards. See Plate LXVI. fig. 5.

CRANAGE, the liberty of uſing a crane at a wharf, and alſo the money paid for drawing up wares out of a ſhip, *&c.* with a crane.

CRANE, in ornithology. See ARDEA.

CRANE, in mechanics, a machine uſed in building and commerce for raiſing large ſtones and other weights. See MECHANICS.

CRANE'S BILL, among ſurgeons, a kind of forceps, ſo called from its figure.

CRANE'S BILL, in botany. See GERANIUM.

CRANE-FLY, in zoology. See TIPULA.

CRANGANOR, a Dutch factory on the Malabar-coaſt, in the hither India, about thirty miles north of Cochin; E. long. 75° 5′, and N. lat. 10°.

CRANIOLARIA, in botany, a genus of the didynamia angioſpermia claſs. The perianthium conſiſts of four leaves, and the ſpatha of one; and the tube of the corolla is very long. There are two ſpecies, none of them natives of Britain.

CRANIUM, in anatomy. See Vol. I. p. 151.

CRANNY, in glaſs-making, an iron-inſtrument, wherewith the necks of glaſſes are formed.

CRAPE, in commerce, a kind of ſtuff, made in the manner of gauze, with raw ſilk, gummed and twiſted on the mill.

CRAPULA, among phyſicians. See SURFEIT.

CRASIS, among phyſicians, is uſed to ſignify ſuch a due mixture of qualities in a human body, as conſtitutes a ſtate of health.

CRASSAMENTUM, in phyſic, the thick red or fibrous part of the blood, otherwiſe called cruor, in contradiſtinction to the ſerum or aqueous part.

CRASSULA, in botany, a genus of the pentandria pentagynia claſs. The calix conſiſts of five leaves, and the corolla of five petals; there are five nectariferous glands at the baſe of the germen; and it has five capſules. There are 17 ſpecies, none of them natives of Britain.

CRATÆGUS, in botany, a genus of the icoſandria digynia claſs. The calix has five ſegments, and the corolla five petals; the berry is below the flower, and contains two ſeeds. There are nine ſpecies, three of which are natives of Britain, *viz.* the aria, or white bean-tree; the torminalis, ſervice-tree, or ſorb; and the oxyacantha, white-thorn, or hawthorn.

CRATCHES, in the menage, a ſwelling on the paſtern, under the fetlock, and ſometimes under the hoof; for which reaſon it is diſtinguiſhed into the ſinew cratches, which affect the ſinew, and thoſe upon the cronet, called quitter-bones.

CRATER, in aſtronomy. See Vol. I. p. 487.

CRATEVA, in botany, a genus of the polyandria monogynia claſs.

CRATO, a town of Alentejo, in Portugal, ſituated about ſeven miles ſouth of Portalegre: W. long. 8°, and N. lat. 38° 50′.

CRAVEN, in geography, a diviſion of the weſt riding of Yorkſhire, ſituated on the river Are.

CRAX, in ornithology, a genus of birds, belonging to the order of gallinæ. The baſe of the beak of each mandible is covered with wax; and the feathers of the head are curled. There are five ſpecies, *viz.* 1. The alecator, or Indian hen of Sloane, is about the ſize of a common hen: It is black, with a white belly. A yellow wax covers about one half of each mandible: The tongue is entire; the temples are bare, and black; the tail is roundiſh, and conſiſts of 14 prime feathers; and it has no ſpur. It is found in the warm parts of America. 2. The rubra, or Peruvian hen, is red, with a blueiſh head: It is a native of Peru. 3. The mitu, or Braſilian pheaſant, is black, with a duſky belly, and red wax: It is a native of Guinea and Brazil.

zil. 4. The globicera, has a yellow protuberance between the noſtrils, and is of a blueiſh black colour: It is likewiſe a native of Brazil. 5. The pauxi, or Mexican pheaſant of Briſſonius, is of a blueiſh colour, with blue wax, and the tip of the tail and belly white: It is a native of Mexico.

CRAYON, a name for all coloured ſtones, earths, or other minerals uſed in deſigning or painting in paſtel. Crayons may be made of any colour, and adapted for the faces of men, women, landſcapes, clouds, ſunbeams, buildings, and ſhadows, in the following manner: Take plaſter of Paris, or alabaſter calcined, and of the colour of which you intend to make your crayons, a ſufficient quantity: grind them firſt aſunder, and then together, and with a little water make them into a paſte: then roll them with your hand upon the grinding ſtone into long pieces, and let them dry moderately in the air: when they are to be uſed, ſcrape them to a point like a common pencil.

CREAM, the fat part of the milk that ſwims upon the ſurface.

Cream *of tartar*. See Chemistry.

CREAT, in the menage, an uſher to a riding maſter; or, a gentleman bred in the academy, with intent to make himſelf capable of teaching the art of riding the great horſe.

CREATION, the producing ſomething out of nothing, which ſtrictly and properly is the effect of the power of God alone, all other creations being only transformations, or change of ſhape.

CREDENTIALS, letters of recommendation, and power, eſpecially ſuch as are given to ambaſſadors, or public miniſters, by the prince or ſtate that ſends them to foreign courts.

CREDIBILITY, a ſpecies of evidence, leſs indeed than abſolute certainty or demonſtration but greater than mere poſſibility: it is nearly allied to probability, and ſeems to be a mean between poſſibility and demonſtration.

CREDIT, in commerce, a mutual truſt or loan of merchandize, or money, on the reputation of the probity and ſufficiency of a dealer. See Commerce.

CREDITON, a market-town in Devonſhire, conſiderable for a good woolen manufactory: it is ſituated about nine miles north-weſt of Exeter, in 3° 50′ W. long. and 50° 50′ N. lat.

CREDITOR, a perſon to whom any ſum of money is due, either by obligation, promiſe, or otherwiſe.

CREED, a brief ſummary of the articles of a Chriſtian's belief.

The moſt ancient form of creeds is that which goes under the name of the apoſtolic creed; beſides this, there are ſeveral other ancient forms and ſcattered remains of creeds to be met with in the primitive records of the church. The firſt is a form of apoſtolical doctrine, collected by Origen; the ſecond is a fragment of a creed preſerved by Tertullian; the third remains of a creed, is in the works of Cyprian; the fourth, a creed compoſed by Gregory Thaumaturgus, for the uſe of his own church; the fifth, the creed of Lucian the martyr; the ſixth, the creed of the apoſtolical conſtitutions. Beſides theſe ſcattered remains of the ancient creeds, there are extant ſome perfect forms, as thoſe of Jeruſalem, Cæſarea, Antioch, *&c.*

The moſt univerſal creeds are, the apoſtolical, the Athanaſian, and the Nicene creeds.

CREEK, the part of a haven where any thing is landed from the ſea.

CREEPER, in ornithology. See Certhia.

CREMA, a city and biſhop's ſee of Italy, capital of a diſtrict of the Milaneſe, called from it Cremaſco: it ſtands almoſt in the middle between Milan and Mantua, in 10° 15′ E. long. and 45° 20′ N. lat.

CREMASTER, in anatomy. See Vol. I. p. 272.

CREMONA, a city of Italy, and capital of a diſtrict of the Milaneſe. called from it the Cremoneſe, is ſituated forty-five miles ſouth-eaſt of Milan, in 10° 30′. E. long. and 45° N. lat.

CRENATED, in botany. See Vol. I. p 640.

CRENCLES, in a ſhip, ſmall ropes, ſpliced into the bolt-ropes of the ſails of the main-maſt and fore-maſt. They are faſtened to the bow-line bridles; and are alſo to hold by, when a bonnet is ſhaken off.

CRENELLE′, or Imbattled, in heraldry, is uſed when any honourable ordinary is drawn, like the battlements on a wall to defend men from the enemies ſhot. See Plate LXVI. fig. 6.

CRENOPHYLAX, in antiquity, a magiſtrate at Athens, who had the inſpection of fountains.

CREPANCE, in the menage, a chop, or cratch, in a horſe's leg, given by the ſpunges of the ſhoes of one of the hinder feet croſſing and ſtriking againſt the other hinder foot. This cratch degenerates into an ulcer.

CREPIS, in botany, a genus of the ſyngeneſia polygamia æqualis claſs. The receptacle is naked; the calix is caliculated, with deciduous ſcales; and the pappus is plumoſe, and furniſhed with a ſtipes The ſpecies are fourteen, three of which are natives of Britain, *viz.* the tectarum, or ſmooth ſuccory hawk-weed; the biennis, or rough ſuccory hawk-weed; and the fœtida, or ſtinking hawk-weed.

CREPUNDIA, in antiquity, a term uſed to expreſs ſuch things as were expoſed along with children, as rings, jewels, *&c.* ſerving as tokens whereby they afterwards might be known.

CRESCENT, the new moon, which, as it begins to recede from the ſun, ſhews a little rim of light, terminating in points, called horns. that are ſtill encreaſing, till it is in oppoſition to the ſun, at which time it is full moon, or quite round.

Crescent, in heraldry, a bearing in form of a new moon. See Plate LXV. fig. 10.

It is uſed either as an honourable bearing, or as the difference to diſtinguiſh between elder and younger families; this being generally aſſigned to the ſecond ſon, and thoſe that deſcend from him. The figure of the creſcent is the Turkiſh ſymbol, with its points looking towards the top of the chief, which is its moſt ordinary repreſentation, called creſcent montant. Creſcents are ſaid to be adoſſed, when their backs are turned towards each other; a creſcent is ſaid to be inverted,

when

when its points look towards the bottom; turned crefcents have their points looking to the dexter fide of the fhield; cornuted crefcents, to the finifter fide; and affronted crefcents, contrary to the adoffed, have their points turned to each other.

CRESCENT, a term among farriers. Thus a horfe is faid to have crefcents when that part of the coffin-bone, which is moft advanced, falls down and preffes the fole outwards, and the middle of her hoof above fhrinks, and becomes flat, by reafon of the hollownefs beneath it.

CRESCENTIA, in botany, a genus of the didynamia angiofpermia clafs. The calix is fplit into two equal parts; the corolla is gibbous; and the berry is unilocular, and contains many feeds. There is but one fpecies, a native of Jamaica.

CRESS, or CRESSES, in botany. See SISYMBRIUM.

Indian CRESS. See TROPÆOLUM.

CRESSY, a port-town of Picardy in France, about forty-four miles fouth of Calais, and twenty-feven north-weft of Abbeville, remarkable on account of the victory obtained there over the French, by Edward III. of England, in the year 1346: E. long. 2°, N. lat. 50° 20′.

CREST, in armoury, the top-part of the armour, for the head, mounting over the helmet, in manner of a comb, or tuft of a cock, deriving its name from *crifta*, a cock's comb.

The creft was for the moft part made of feathers, or the hair of horfes tails or mains. The foldiers took great pride in adorning them.

CREST, in heraldry, the uppermoft part of an armoury, or that part of the cafk or helmet next to the mantle. Guillim fays, the creft, or cognizance, claims the higheft place, being feated on the moft eminent part of the helmet; yet fo as to admit of an interpofition of fome efcrol, wreathe, chapeau, crown, *&c.*

The creft is efteemed a greater mark of nobility than the armory; being borne at tournaments, to which none were admitted till fuch time as they had given proof of their nobility: fometimes it ferves to diftinguifh the feveral branches of a family; and it has ferved, on occafion, as a diftinguifhing badge of factions: fometimes the creft is taken for the device; but more ufually is formed of fome piece of the arms. Families that exchange arms do not change their creft.

CREST, among carvers, an imagery, or carved work, to adorn the head or top of any thing, like our modern corniche.

CREST-*fallen*, a fault of an horfe, when the upper part of his neck, called the creft, hangs to one fide: this they cure by placing it upright, clipping away the fpare fkin, and applying plafters to keep it in a proper pofition.

CRESTED, fomething furnifhed with a creft. See CREST.

CRETA, or CHALK, in natural-hiftory. See CHALK.

CREUX, a French term ufed among artifts, and literally fignifies a hollow cavity or pit, out of which fomething has been fcooped or dug: whence it is ufed to fignify that kind of fculpture, where the lines and figures are cut and formed within the face or plan of the plate or matter engraved; and thus it ftands in oppofition to relievo, where the lines and figures are emboffed, and rife prominent above the face of the matter engraved on.

CREW, the company of failors belonging to a fhip, boat, or other veffel.

CREX, in ornithology. See RALLUS.

CRIBBAGE, a game at cards, to be learnt only by practice.

CRIBRATION, in pharmacy, the paffing any fubftance through a fieve, or fearch, in order to feparate the finer particles from the groffer.

CRIBROSUM *os*, in anatomy, called alfo os ethmoides. See Vol. I. p. 157.

CRICETUS, in zoology. See MUS.

CRICK, among farriers, is when a horfe cannot turn his neck any manner of way, but holds it fore right, infomuch that he cannot take his meat from the ground without great pain.

CRICKET, in zoology. See GRYLLUS.

Mole-CRICKET. See GRYLLOTALPA.

CRICKLADE, a borough-town of Wiltfhire, fituated on the river Ifis, about twenty-fix miles fouth-weft of Oxford: W. long. 1° 55′, and N. lat. 51° 35′.

CRICO-ARYTANOIDÆUS, in anatomy. See Vol. I. p. 300.

CRICOIDES, in anatomy. See Vol. I. p. 300.

CRICO-THYROIDÆUS, in anatomy. See Vol. I. p. 300.

CRIM, or CRIM-TARTARY, a peninfula in the Black fea, between 33° and 37° E. long. and between 44° and 46° N. lat. It is joined to Little Tartary by a narrow ifthmus.

CRIME, the tranfgreffion of a law, either natural or divine, civil or ecclefiaftic.

CRIMSON, one of the feven red colours of the dyers. See DYING.

CRINONES, among phyficians, fmall worms that breed in the fkin, called alfo dracunculi.

CRINUM, in botany, a genus of the hexandria monogynia clafs. The corolla is tunnel-fhaped, and confifts of one leaf, divided into fix fegments; and the germen is at the bottom of the corolla. There are four fpecies, none of them natives of Britain.

CRISIS, in medicine, is ufed in different fenfes, both by the ancient and modern phyficians. With fome it means frequently no more than the excretion of any noxious fubftance from the body. Others take the word for a fecretion of the noxious humours made in a fever. Others ufe it for the critical motion itfelf; and Galen defines a crifis in fevers, a fudden and inftantaneous change, either for the better or the worfe, productive of recovery or death.

CRISTÆ, in furgery, a term for certain excrefcences about the anus and pudenda. See Vol. I. p. 157.

CRISTA GALLI, in anatomy. See Vol. I. p. 157.

CRISTA GALLI, or COCK'*s* COMB. See RHINANTHUS.

CRISTA PAVONIS, in botany. See POINCIANA.

CRITERIUM, a ftandard by which propofitions and opinions are compared, in order to difcover their truth or falfehood.

CRITHE, in furgery, commonly called the ftye, is a tubercle that grows in different parts of the eye lids.

CRITHMUM, in botany, a genus of the pentandria digynia clafs. The fruit is oval and compreffed. There are two fpecies, one of which, *viz.* the maritimum, or fampire, is a native of Britain; the leaves are faid to be ftomachic, aperient, and diuretic.

CRITICAL *days* and *fymptoms*, among phyficians, are certain days and fymptoms in the courfe of acute difeafes, which indicate the patient's ftate, and determine him either to recover or grow worfe. See MEDICINE.

CRITICISM, the art of judging with propriety concerning any object or combination of objects. But, in a more limited fenfe, the fcience of criticifm is confined to the fine arts. The principles of the fine arts are beft unfolded by ftudying the fenfitive part of our nature, and by learning what objects are naturally agreeable, and what are naturally difagreeable. The man who afpires to be a critic in thefe arts, muft pierce ftill deeper: he muft clearly perceive what objects are lofty, what low, what are proper or improper, what are manly, and what are mean or trivial. Hence a foundation for judging of tafte, and for reafoning upon it: where it is conformable to principles, we can pronounce with certainty, that it is correct; otherwife, that it is incorrect, and perhaps whimfical. Thus the fine arts, like morals, become a rational fcience; and, like morals, may be cultivated to a high degree of refinement.

Manifold are the advantages of criticifm, when thus ftudied as a rational fcience. In the firft place, a thorough acquaintance with the principles of the fine arts, redoubles the entertainment thefe arts afford. To the man who refigns himfelf entirely to fentiment or feeling, without interpofing any fort of judgment, poetry, mufic, painting, are mere paftime; in the prime of life, indeed, they are delightful, being fupported by the force of novelty, and the heat of imagination: but they lofe their relifh gradually with their novelty; and are generally neglected in the maturity of life, which difpofes to more ferious and more important occupations. To thofe who deal in criticifm as a regular fcience, governed by juft principles, and giving fcope to judgment as well as to fancy, the fine arts are a favouraite entertainment; and in old age maintain that relifh which they produce in the morning of life.

In the next place, a philofophical inquiry into the principles of the fine arts, inures the reflecting mind to the moft enticing fort of logic: the practice of reafoning upon fubjects fo agreeable tends to a habit; and a habit ftrengthening the reafoning faculties, prepares the mind for entering into fubjects more difficult and abftract. To have, in this refpect, a juft conception of the importance of criticifm, we need but reflect upon the common method of education; which, after fome years fpent in acquiring languages, hurries us, without the leaft preparatory difcipline, into the moft profound philofophy: a more effectual method to alienate the tender mind from abftract fcience, is beyond the reach of invention; and accordingly, with refpect to fuch fpeculations, the bulk of our youth contract a fort of hobgoblin terror, which is feldom, if ever fubdued. Thofe who apply to the arts, are trained in a very different manner: they are led, ftep by ftep, from the eafier parts of the operation, to what are more difficult; and are not permitted to make a new motion, till they be perfected in thofe which regularly precede it. The fcience of criticifm appears then to be a middle link, connecting the different parts of education into a regular chain. This fcience furnifheth an inviting opportunity to exercife the judgment: we delight to reafon upon fubjects that are equally pleafant and familiar; we proceed gradually from the fimpler to the more involved cafes: and in a due courfe of difcipline, cuftom, which improves all our faculties, beftows acutenefs upon thofe of reafon, fufficient to unravel all the intricacies of philofophy.

Nor ought it to be overlooked, that the reafonings employed upon the fine arts are of the fame kind with thofe which regulate our conduct. Mathematical and metaphyfical reafonings have no tendency to improve focial intercourfe; nor are they applicable to the common affairs of life: but a juft tafte in the fine arts, derived from rational principles, furnifhes elegant fubjects for converfation, and prepares us finely for acting in the focial ftate with dignity and propriety.

The fcience of rational criticifm tends to improve the heart not lefs than the underftanding. It tends, in the firft place, to moderate the felfifh affections: by fweetening and harmonizing the temper, it is a ftrong antidote to the turbulence of paffion and violence of purfuit: it procures to a man fo much mental enjoyment, that in order to be occupied, he is not tempted in youth to precipitate into hunting, gaming, drinking; nor in middle-age, to deliver himfelf over to ambition; nor in old-age, to avarice. Pride and envy, two difguftful paffions, find in the conftitution no enemy more formidable than a delicate and difcerning tafte: the man upon whom nature and culture have beftowed this bleffing, feels great delight in the virtuous difpofitions and actions of others: he loves to cherifh them, and to publifh them to the world: faults and failings, it is true, are to him not lefs obvious; but thefe he avoids, or removes out of fight, becaufe they give him pain. On the other hand, a man void of tafte, upon whom the moft ftriking beauties make but a faint impreffion, has no joy but in gratifying his pride or envy by the difcovery of errors and blemifhes. In a word, there may be other paffions, which, for a feafon, difturb the peace of fociety more than thofe mentioned; but no other paffion is fo unwearied an antagonift to the fweets of focial intercourfe: thefe paffions, tending affiduoufly to their gratification, put a man perpetually in oppofition to others; and difpofe him more to relifh bad than good qualities, even in a companion. How different that difpofition of mind, where every

virtue

virtue in a companion or neighbour, is, by refinement of tafte, fet in its ftrongeft light; and defects or blemifhes, natural to all, are fuppreffed, or kept out of view!

In the next place, delicacy of tafte tends not lefs to invigorate the focial affections, than to moderate thofe that are felfifh. To be convinced of this tendency, we need only reflect, that delicacy of tafte neceffarily heightens our fenfibility of pain and pleafure, and of courfe our fympathy, which is the capital branch of every focial paffion. Sympathy in particular invites a communication of joys and forrows, hopes and fears: fuch exercife, foothing and fatisfactory in itfelf, is neceffarily productive of mutual good-will and affection.

One other advantage of rational criticifm is referved to the laft place, being of all the moft important; which is, that it is a great fupport to morality. No occupation attaches a man more to his duty than that of cultivating a tafte in the fine arts: a juft relifh of what is beautiful, proper, elegant, and ornamental, in writing or painting, in architecture or gardening, is a fine preparation for the fame juft relifh of thefe qualities in character and behaviour. To the man who has acquired a tafte fo acute and accomplifhed, every action wrong or improper, muft be highly difguftful: if, in any inftance, the overbearing power of paffion fway him from his duty, he returns to it upon the firft reflection, with redoubled refolution never to be fwayed a fecond time: he has now an additional motive to virtue, a conviction derived from experience, that happinefs depends on regularity and order, and that a difregard to juftice or propriety never fails to be punifhed with fhame and remorfe.

For the rules of criticifm, applicable to the fine arts, and derived from human nature, fee ARCHITECTURE, BEAUTY, CONGRUITY, COMPARISON, GRANDEUR, *&c.*

CROATIA, a frontier province of Germany, bounded by Sclavonia on the north and eaft, by Bofnia on the fouth, and by Carniola on the weft. It is fubject to the houfe of Auftria.

CROCCEUS, or HOAMEO, a large river of China, which, after a courfe of two thoufand miles, falls into the bay of Nankin: it is fometimes called the Yellow river, on account of the flime of this colour with which its waters are tinged.

CROCINUM, among phyficians, denotes the oil of faffron, faid to be of a heating quality, and to procure fleep.

CROCODES, an appellation given to paftils or troches, whereof crocus, or faffron, is the principal ingredient.

CROCODILE, in zoology. See LACERTA.

CROCUS, or SAFFRON, in botany, a genus of the triandria monogynia clafs. The corolla is divided into fix equal parts; and it has three erect ftigmata. There is but one fpecies, a native of Britain. The antheræ, or cluves, picked off and preffed together into cakes, goes by the name of faffron, which is an elegant and ufeful aromatic, and is defervedly accounted one of the higheft cordials.

CROCUS, in chemiftry, denotes any metal calcined to a red or deep yellow colour. See CHEMISTRY.

CROCUS METALLORUM, an emetic preparation of antimony and nitre. See CHEMISTRY.

CROFT, a little clofe adjoining to a dwelling-houfe, and enclofed for pafture or arable land, or any other particular ufe.

CROISADE, CRUSADE, or CRUZADO, a name given to the expeditions of the Chriftians againft the infidels, for the conqueft of Paleftine; fo called, becaufe thofe who engaged in the undertaking wore a crofs on their cloaths, and bore one on their ftandard.

This expedition was alfo called the holy war, to which people flocked in great numbers out of pure devotion, the pope's bulls and the preaching of the priefts of thofe days making it a point of confcience. The feveral nations engaged in the holy war were diftinguifhed by the different colours of their croffes: the Englifh wore white, the French red, the Flemifh green, the Germans black, and the Italians yellow. From this enterprife feveral orders of knighthood took their rife. They reckon eight croifades for the conqueft of the holy land; the firft begun in the year 1095, at the folicitation of the Greek emperor and the patriarch of Jerufalem.

CROISES, or CROIZES, in Englifh antiquity, pilgrims bound for the holy land, or fuch as had been there; fo called from a badge they wore in imitation of a crofs. The knights of St John of Jerufalem, created for the defence and protection of pilgrims, were particularly called croifes.

CROISIERS, a religious order founded in honour of the invention or difcovery of the crofs by the emprefs Helena.

They are difperfed in feveral parts of Europe, particularly in the Low Countries, France, and Bohemia, thofe in Italy being at prefent fuppreffed. Thefe religious follow the rule of St Auguftine. They had in England the name of crouched friers.

CROMARTY, the capital of the fhire of Cromarty, in Scotland, with an excellent and fafe harbour capable of containing the greateft fleets: W. long. 3° 40′, and N. lat. 57° 54′.

CRONENBURG, a fortrefs of Denmark, fituated in the ifland of Zealand, at the entrance of the Sound, where the Danes take toll of fhips bound for the Baltic: E. long. 12° 5′, and N. lat. 56°.

CRONSLOT, or CROWN-CASTLE, a caftle and harbour in a little ifland of the fame name, at the mouth of the river Neva, and entrance of the gulf of Finland, in Ruffia, about twelve miles weft of Peterfburgh: E. long. 30°, and N. lat. 60°. Here is a ftation for the Ruffian men of war, and a yard for building and refitting them.

CRONSTAT, a town of Tranfilvania, fituated near the frontiers of Moldavia, about fifty miles north-eaft of Hermanftat, and fubject to the houfe of Auftria: E. long. 25°, and N. lat. 47′.

CROPPER, in ornithology. See Columba.

CROSIER, or Crozier, a ſhepherd's crook; a ſymbol of paſtoral authority, conſiſting of a gold or ſilver ſtaff, crooked at the top, carried occaſionally before biſhops and abbots, and held in the hand when they give the ſolemn benedictions. The cuſtom of bearing a paſtoral ſtaff before biſhops is very ancient. Regular abbots are allowed to officiate with a mitre and croſier. Among the Greeks none but a patriarch had a right to the croſier.

Crosier, in aſtronomy, four ſtars in the ſouthern hemiſphere, in the form of a croſs, ſerving thoſe who ſail in ſouth latitudes to find the antarctic pole.

CROSLET, in heraldry, is when a croſs is croſſed again at a ſmall diſtance from each of the ends. Upton ſays it is not ſo often borne by itſelf in arms, as other croſſes are, but often in diminutives, that is, in ſmall croſſets ſcattered about the field. See Plate LXVI. fig. 7.

CROSS, in antiquity, a ſpecies of puniſhment, or rather the inſtrument wherewith it was inflicted, conſiſting of two pieces of wood croſſing each other.

This puniſhment was only inflicted on malefactors and ſlaves, and thence called *ſervile ſupplicium*. The moſt uſual method was to nail the criminal's hands and feet to this machine, in an erect poſture; though there are inſtances of criminals ſo nailed with their head downward.

Invention of the Cross, a feſtival obſerved on May 3, by the Latin church, in memory of the empreſs Helena's (the mother of Conſtantine) finding the true croſs of Chriſt on mount Calvary, where ſhe cauſed erect a church for the preſervation of it.

Exaltation of the Cross, a grand feſtival ſolemnized on September 14, in commemoration of Heraclius's reſtoring to mount Calvary the true croſs, that had been carried off by Coſroes king of Perſia, upon taking the city of Jeruſalem.

Order of the Cross, an order of ladies inſtituted in 1668, by the empreſs Eleanora de Gonzagua, wife of the emperor Leopold, on occaſion of the miraculous recovery of a little golden croſs, wherein were incloſed two pieces of the true croſs, out of the aſhes of a part of the palace that had been burnt down: though the fire burnt the caſe wherein it was encloſed, and melted the cryſtal, it appears that the wood had not received the leaſt damage.

Cross, in heraldry, an ordinary compoſed of fourfold lines, whereof two are perpendicular, and the other two tranſverſe; for ſo we muſt conceive of them, though they are not drawn throughout, but meet, by couples, in four right angles, near about the feſſe-point of the eſcutcheon. The content of a croſs is not always the ſame; for when it is not charged, it has only the fifth part of the field; but if it be charged, then it muſt contain the third part thereof.

This bearing was beſtowed on ſuch as had performed, or at leaſt undertaken ſome ſervice for Chriſt and the Chriſtian profeſſion; and is therefore held by ſeveral authors the moſt honourable charge in all heraldry. What brought it into ſuch frequent uſe was the ancient expeditions into the holy land, the croſs being the enſigns of that war.

In theſe wars, the Scots carried St Andrew's croſs; the French, a croſs argent; the Engliſh, a croſs or; the Germans, ſable; the Italians, azure; the Spaniards, gules.

Cross bar-shot, a bullet with an iron-bar paſſing through it, and ſtanding ſix or eight inches out at both ſides: it is uſed at ſea, for deſtroying the enemy's rigging.

Cross-bill, in ornithology. See Loxia.

Cross-wort, in botany. See Valantia.

CROSSELET, a little or diminutive croſs, uſed in heraldry, where the ſhield is frequently ſeen covered with croſſelets; alſo feſſes and other honourable ordinaries, charged or accompanied with croſſelets. Croſſes frequently terminate in croſſelets. See Plate LXVI. fig. 7.

CROTALARIA, in botany, a genus of the diadelphia decandria claſs. The pod is ſwollen, inflated, and pedicellated. There are eleven ſpecies, none of them natives of Britain.

CROTALOPHORUS, in zoology. See Crotalus.

CROTALUS, or Rattle-snake, in zoology, a genus belonging to the order of amphibia ſerpentes, the characters of which are theſe: The belly is furniſhed with ſcuta, and the tail has both ſcuta and ſcales; but the principal characteriſtic of this genus, is the rattle at the end of the tail. The rattles conſiſt of ſeveral articulated cruſtaceous, or rather horny bags, which make a conſiderable rattling noiſe when the creature moves, and ſerves to warn people of their approach. There are five ſpecies, and the bite of every one of them is ſo highly poiſonous, that it generally kills in a ſhort time. 1. The horridus, or American rattleſnake, has 167 ſcuta, and 23 ſcutellæ. It is generally of an orange, tawny, or blackiſh colour on the back, and the belly is aſh coloured: they are from four to ſix inches in length; ſome are as thick as a man's leg: Dr Tyſon diſſected one which was four feet five inches long, and the body ſix and a half inches in diameter. They devour birds, ſquirrels, hares, &c. 2. The miliaris has 13 ſcuta, and 31 ſcutellæ. It is aſh-coloured, interſperſed with black ſpots, and is a native of Carolina. 3. The dryinas has 165 ſcuta, and 30 ſcutellæ. It is whitiſh, with a few yellow ſpots, and is a native of America. 4. The duriſſus has 172 ſcuta, and 21 ſcutellæ. It is variegated with white and yellow colours, and is likewiſe found in America. 5. The mutus has 217 ſcuta, and 34 ſcutellæ. It has a chain of rhomboidal black ſpots on the back, a black line behind the eyes, and is a native of Surinam.

CROTCHET, in muſic, one of the notes or characters of time, marked thus ♩, equal to half a minum, and double of a quaver.

Crotchets are alſo marks or characters, ſerving to incloſe a word or ſentence which is diſtinguiſhed from the reſt, being generally in this form [ ], or this ( ).

CROTON, in botany, a genus of plants of the monoecia polyandria claſs. The calix of the male is cylindrical,

drical, and has five teeth; the corolla has five petals; and the ſtamina are from 10 to 15. The calix of the female conſiſts of many leaves; it has no corolla; but has three bifid ſtyli; and the capſule has three cells, and contains one ſeed. There are 21 ſpecies, none of them natives of Britain.

CROTOY, a town of France, ſituated in the province of Picardy, at the mouth of the river Somme: E. long. 1° 30′, and N. lat. 50° 15′.

CROUP *of a horſe*, in the menage, the extremity of the reins above the hips.

CROUPADE, in the menage, a leap, in which the horſe pulls up his hind legs, as if he drew them up to his belly.

CROW, or CARRION-CROW, in ornithology. See CORVUS.

Royſton CROW. See CORVUS.

CROW, in mechanics, a kind of iron lever, with a claw at one end, and a ſharp point at the other; uſed for heaving or purchaſing great weights.

CROW'S BILL, among ſurgeons, a kind of forceps, for drawing bullets and other foreign bodies out of wounds.

CROW-FLOWERS, in botany. See LYCHNIS.

CROW'S FEET, in the military art, machines of iron, having four points, each about three or four inches long, ſo made, that whatever way they fall, there is ſtill a point up: they are thrown upon breaches, or in paſſes where the enemy's cavalry are to march, proving very troubleſome by running into the horſe's feet and laming them.

CROW'S FEET, in a ſhip, ſmall lines or ropes, ſometimes eight or ten, reeved through the deadmens eyes; and ſcarce of any other uſe than to make a ſhew of ſmall rigging. They are uſually placed at the bottom of the back-ſtays of the fore-top-maſt, mizen-top-maſt, and gallant-top-maſt.

CROW'S FOOT, in botany. See RANUNCULUS.

CROWLAND, a market-town of Lincolnſhire: W. long. 10′, and N. lat. 52° 40′.

CROWN, an ornament worn on the head by kings, ſovereign princes, and noblemen, as a mark of their dignity.

In ſcripture there is frequent mention of crowns, and the uſe of them ſeems to have been very common among the Hebrews. The high prieſt wore a crown, which was a fillet of gold placed upon the forehead, and tied with a ribbon of hyacinth colour, or azure blue. It ſeems alſo as if private prieſts, and even common Iſraelites, wore alſo a ſort of crown, ſince God commands Ezekiel not to take off his crown, nor aſſume the marks of one in mourning. This crown was no more than a ribbon or fillet, with which the Jews and ſeveral people in the eaſt girt their heads. And indeed the firſt crowns were no more than a bandelet drawn round the head, and tied behind, as we ſtill ſee it repreſented on medals round the heads of Jupiter, the Ptolemies, and kings of Syria. Afterwards they conſiſted of two bandelets: by degrees they took branches of trees of divers kinds; at length they added flowers, inſomuch that Claudius Saturninus ſays, there was not any plant whereof crowns had not been made. The woods and groves were ſearched to find different crowns for the ſeveral deities; and they were uſed not only on the ſtatues and images of the gods, by the prieſts in ſacrificing, and by kings and emperors, but alſo on altars, temples, doors of houſes, ſacred veſſels, victims, ſhips, *&c.*

The Roman emperors had four kinds of crowns, ſtill ſeen on medals, *viz.* a crown of laurel, a radial or radiating crown, a crown adorned with pearls and precious ſtones, and the fourth a kind of bonnet or cap, ſomething like the mortier.

The Romans had alſo various kinds of crowns, which they diſtributed as rewards of military atchievements; as, 1. The oval crown, made of myrtle, and beſtowed upon generals, who were entitled to the honours of the leſſer triumph, called ovation. 2. The naval or roſtral crown, compoſed of a circle of gold, with ornaments repreſenting beaks of ſhips, and given to the captain who firſt grappled, or the ſoldier who firſt boarded, an enemy's ſhip. 3. The crown called in Latin vallaris, or caſtrenſis, a circle of gold raiſed with jewels or paliſades; the reward of him who firſt forced the enemy's entrenchments. 4. The mural crown, a circle of cold indented and embattled; given to him who firſt mounted the wall of a beſieged place, and there lodged a ſtandard. 5. The civic crown, made of the branch of a green oak, and given him who had ſaved the life of a citizen. 6. The triumphal crown, conſiſting at firſt of wreaths of laurel, but afterwards made of gold; proper to ſuch generals as had the honour of a triumph. 7. The crown called obſidionalis, or graminea, made of graſs growing on the place; the reward of a general who had delivered a Roman army from a ſiege. 8. The crown of laurel, given by the Greeks to their athletæ; and by the Romans to thoſe who had negociated or confirmed a peace with an enemy: this was the leaſt honourable of all. We meet alſo with the corona aurea, often beſtowed on ſoldiers, without any other additional term; the radial crown, given to princes at their tranſlation among the gods; athletic crowns, and crowns of laurel, deſtined to crown victims at the public games, poets, orators, *&c.* All theſe crowns were marks of nobility to the wearers; and upon competitions with rivals for rank and dignities, often determined the preference in their favour. See Plate LXVI. fig. 8, n°. 1. 2. 3. *&c.*

The Imperial CROWN is a bonnet or tiara, with a ſemicircle of gold, ſupporting a globe with a croſs at top. See Plate LXVI. fig. 9. n°. 1.

The Britiſh CROWN is adorned with four croſſes, between which there are four fleurs de lis: it is covered with four diadems, which meet at a little globe ſupporting a croſs. *Ibid.* n°. 2.

The French CROWN, is a circle of eight fleurs de lis, encompaſſed with ſix diadems, bearing at top a double fleurs de lis, which is the creſt of France. *Ibid.* n°. 3.

The Spaniſh CROWN is adorned with large indented leaves, and covered with diadems terminating in a globe, ſurmounted with a croſs. *Ibid.* n°. 4.

The crowns of almoſt all other kings are adorned with large leaves, bordered with four, ſix, or eight diadems, with a globe and croſs at top.

The Papal CROWN is compoſed of a tiara, and a triple crown encompaſſing it, with two pendants like the biſhop's mitres. Theſe crowns repreſent the pretended triple capacity of the pope, as high prieſt, ſupreme judge, and ſole legiſlator of Chriſtians. *Ibid.* n°. 5.

An electoral CROWN, or coronet, is a ſcarlet cap turned up with ermine, and cloſed with a ſemicircle of gold, all covered with pearls, with a globe at top, ſurmounted with a golden croſs. *Ibid.* n°. 6.

CROWNS *of Britiſh princes of the blood.* 1. The prince of Wales's crown conſiſts alternately of croſſes and fleurs de lis, with one arch, in the middle of which is a ball and croſs, as in the royal diadem. 2. That of all the younger ſons and brothers of the king, conſiſts likewiſe of croſſes and fleurs de lis alternately, but without any arch, or being ſurmounted with a globe and croſs at top. 3 That of the other princes of the blood conſiſts alternately of croſſes and leaves, like thoſe in the coronet of dukes, *&c. Ibid.* fig. 10. n°. 1. 2. 3.

CROWNS *of noblemen* are, a duke's, compoſed of leaves of ſmallage, or parſley: that of a marquis, of flowers and pearls placed alternately: an earl's has no flowers about the circle, like the duke and marquis, but only points riſing, and a pearl on every one of them: a viſcount has neither flowers nor points raiſed above the circle, like the other ſuperior degrees, but only pearls placed on the circle itſelf without any limited number: a baron's has only ſix pearls on the golden border, not raiſed, to diſtinguiſh him from the earl's; and the number of them limited, to ſhew he is inferior to the viſcount. *Ibid.* fig. 11. n°. 1. 2. *&c.*

CROWN, in commerce, a general name for coins both foreign and domeſtic, which are of, or very near, the value of five ſhillings ſterling.

CROWN-OFFICE, an office belonging to the king's bench court, of which the king's coroner or attorney is commonly maſter. In this office, the attorney general and clerk of the crown ſeverally exhibit informations for crimes and miſdemeanors at common law, as in the caſe of batteries, conſpiracies, libelling, *&c.* on which the offender is liable to pay a fine to the king.

CROWN-GLASS, denotes the fineſt ſort of window-glaſs. See GLASS.

CROWN-WHEEL *of a watch*, the upper wheel next the balance, which by its motion drives the balance, and in royal pendulums is called the ſwing-wheel

CROWN IMPERIAL, in botany. See FRITILLARIA.

CROYDON, a market-town in Surrey, about ten miles ſouth of London.

CRUCIAL INCISION, in ſurgery, an inciſion made in form of a croſs.

CRUCIANELLA, in botany, a genus of the tetrandria monogynia claſs. The corolla conſiſts of one turnnel-ſhaped petal, with a filiform tube; the calix has three leaves; and the ſeeds are two, ſituate between the calix and corolla. The ſpecies are five, none of them natives of Britain.

CRUCIATA, in botany. See VALENTIA.

CRUCIBLE, a chemical veſſel made of earth, and ſo tempered and backed as to endure the greateſt fire. They are uſed to melt metals, and to flux minerals, ores, *&c.*

The figure of a crucible is commonly that of an obtuſe conoid, with its baſe at the top, and obtuſe apex at the bottom; whence this conical figure may be varied, till it comes to the hollow ſegment of a ſphere.

The crucibles moſt generally uſed are thoſe of Heſſe and Auſtria.

CRUCIFIX, a croſs upon which the body of Chriſt is faſtened in effigy, uſed by the Roman-catholics to excite in their minds a ſtrong idea of our Saviour's paſſion.

They eſteem it an eſſential circumſtance of the religious worſhip performed at the altar; and on Good Friday they perform the ceremony of adoring it, which is done in theſe words, *O crux ave, ſpes unica; Hail, thou croſs, our only hope.* The officiating prieſt uncovers the crucifix, elevates it with both his hands, and ſays, *Ecce lignum crucis; Behold the wood of the croſs.* The people anſwer, *in quo ſalus mundi pependit*; *on which the Saviour of the world ſuffered death.* Then the whole congregation bow with great reverence, and devoutly kiſs the holy wood.

CRUCIFIXION, a capital puniſhment by nailing the criminal to a croſs. See CROSS.

CRUCIFORM, in general, ſomething diſpoſed croſswiſe; but more eſpecially uſed by botaniſts, for flowers conſiſting of four petals diſpoſed in the form of a croſs.

CRUDE, an epithet given to ſomething that has not paſſed the fire, or had a proper degree of coction.

CRUDITY, among phyſicians, is applied to undigeſted ſubſtances in the ſtomach; to humours in the body which are unconcocted, and not prepared for expulſion; and to the excrements.

CRUISE, in the ſea-language, ſignifies to ſail back and fore within a certain ſpace of the ſea, as well to annoy the enemy, as to protect our own trading veſſels.

CRUMENTATA, among zoologiſts, animals furniſhed with a pouch, or bag, wherein to receive their young in time of danger.

CRUOR, ſometimes ſignifies the blood in general; ſometimes only the venous blood; and ſometimes extravaſated, or coagulated blood.

CRUPPER, in the menage, the buttocks of a horſe, the rump; alſo a thong of leather put under a horſe's tail, and drawn up by thongs to the buckle behind the ſaddle, ſo as to keep him from caſting the ſaddle forwards on his neck.

CRURA CLITORIDIS, in anatomy. See Vol. I. p. 276.

CRURA MEDULLÆ OBLONGATÆ. See Vol. I. p. 287.

CRURÆUS, or CRUREUS MUSCULUS, in anatomy. See Vol. I. p. 207.

CRURAL, in anatomy, an epithet given to the artery which conveys the blood to the crura, or legs, and to the

the vein by which this blood returns towards the heart. See ANATOMY, Part III. IV.

CRUS, in anatomy, all that part of the body contained between the buttocks and the toes. See ANATOMY, Part I.

CRUSCA, an Italian term ſignifying bran, is in uſe amongſt us to denote that celebrated academy called *della cruſca*, eſtabliſhed at Florence, for purifying and perfecting the Tuſcan language.

CRUSTA VILLOSA, in anatomy. See Vol. I. p. 258.

CRUSTA LACTEA, in medicine, the ſame with achor, being ſcabby eruptions with which the heads of children are often troubled. See MEDICINE.

CRUSTACEOUS, an appellation given to animals covered with ſhells made up of ſeveral pieces, in contradiſtinction to thoſe conſiſting of a ſingle piece.

CRUX, or St CROIX, one of the Caribbee-iſlands, ſitutuated about ſixty miles ſouth-eaſt of Porto-Rico, and ſubject to France: W. long. 64°, and N. lat. 17° 30′.

CRUSADO, in commerce, a Portugueſe coin, ſtruck under Alphonſus V. about the year 1457, at the time when pope Calixtus ſent thither the bull for a croiſade againſt the infidels.

This coin has a croſs on one ſide, and the arms of Portugal on the other.

CRYMODES, among phyſicians, a kind of fever attended with a ſhivering cold and inflammation of the internal parts of the body.

CRYPTOGAMIA, in botany. See the *Scheme*, p. 635. and Plate LIII. fig. 24. alſo p. 636.

CRYPTOGRAPHY, the art of writing in cipher, or with ſympathetic ink. See CIPHER and INK.

CRYSTAL, the name of a very large claſs of foſſils; hard, pellucid, and naturally colourleſs; of regularly angular figures, compoſed of ſimple, not filamentous plates; not flexible nor elaſtic, giving fire with ſteel; not fermenting in acid menſtrua, and calcining in a ſtrong fire.

The orders of pure cryſtal are three; the firſt is perfect columnar cryſtals, with double pyramids, compoſed of eighteen planes, in an hexangular column, terminated by an hexangular pyramid at each end: the ſecond order is that of perfect cryſtals, with double pyramids, without a column, compoſed either of twelve or of ſixteen planes, in two hexangular pyramids, joined cloſely, baſe to baſe, without the intervention of any column: the third order is that of imperfect cryſtals, with ſingle pyramids, compoſed either of twelve or ten planes, in an hexangular or pentangular column, affixed irregularly, at one end, to ſome ſolid body, and terminated, at the other, by an hexangular or pentangular pyramid.

Theſe are all the general forms into which cryſtal, when pure, is found concreted: but under theſe there are almoſt infinite varieties in the number of angles, and the length, thickneſs, and other accidents of the columns and pyramids.

When cryſtal is blended with metalline particles at the time of its formation, it aſſumes a variety of figures wholly different from theſe, conſtituting a fourth order, under the name of metalline cryſtals: when that metal is lead, the cryſtal aſſumes the form of a cube; when it is tin, of a quadrilateral pyramid, with a broad baſe; when iron, the cryſtal is found concreted in rhomboidal cryſtals: theſe cryſtals are very common about mines; but the common ſpars, which are liable to be influenced in the ſame manner by the metals, and to appear in the very ſame form, are to be carefully diſtinguiſhed from them. There is one very eaſy teſt for this purpoſe, which is, that all ſpars are ſubject to be diſſolved by aqua fortis, and effervefce violently only on its touching it: but it has no ſuch effects on cryſtal.

The pebble cryſtal is common enough in all parts of the world; but that which is formed of hexangular columns, affixed to a ſolid baſe at one end, and terminated by a hexangular column at the other, is infinitely more ſo: this is what we call ſprig or rock cryſtal, and is the ſpecies deſcribed by moſt authors under the name of cryſtal of the ſhops, or that kept for medicinal uſe.

It is to be choſen the cleareſt, pureſt, and moſt tranſparent that can be had: it ſhould be proved to be no ſpar, by means of aquafortis, or by drawing a point of it along a pane of glaſs, which it cuts in the manner of a diamond. It is found in vaſt abundance in many parts of England and Ireland; and in Germany it is yet more frequent. It is found about Briſtol of amethyſtine tinge; in Sileſia and Bohemia it is ſtained to the colour of the ruby, ſapphire, emerald, and topaz, in which caſe jewellers make great advantage of it, ſelling it under the name of accidental ſapphire, *&c.*

CRYSTAL is alſo uſed for a factitious body, caſt in glaſs-houſes, called cryſtal-glaſs; being, in fact, no more than glaſs carried, in the compoſition and manufacture, to a greater perfection than the common glaſs.

The beſt kind of glaſs-cryſtal is that called Venice cryſtal, made at Moran, near Venice. See GLASS.

CRYSTALS, in chemiſtry, ſalts or other matters ſhot, or congealed, in the manner of cryſtal. See CHEMISTRY.

CRYSTALLINE HUMOUR, in anatomy. See Vol. I. p. 289.

CRYSTALLIZATION, in chemiſtry. See CHEMISTRY.

CRYSTALLOMANCY, in antiquity, a kind of divination, performed by means of a mirror, wherein the figures of the things required are ſaid to have been repreſented.

CUB, a bear's whelp. Among hunters, a fox and martern of the firſt year, are called cubs. See URSUS.

CUBA, an iſland of North America, ſituated in the Atlantic ocean, between 74° and 87° of W. long. and between 20° and 23° N. lat. being eight hundred miles and upwards in length from eaſt to weſt, and generally about ſeventy miles broad. It lies about fifty miles weſt of Hiſpaniola, and ſeventy-five north of Jamaica.

CUBAGUA, an American iſland, ſituated between the iſland of Margaretta and Terra Firma, and ſubject to Spain: W. long. 64°, and N. lat. 10° 15′.

CUBE, in geometry, a ſolid body, conſiſting of ſix equal ſquare ſides. See Geometry.

CUBEBS, in the materia medica, a ſmall dried fruit, reſembling a grain of pepper, but often ſomewhat longer, brought into Europe from the iſland of Java. In aromatic warmth and pungency, they are far inferior to pepper.

CUBIC, or Cubical equation, in algebra. See Algebra.

CUBIT, in the menſuration of the ancients, a long meaſure, equal to the length of a man's arm, from the elbow to the tip of the fingers.

Dr Arbuthnot makes the Engliſh cubit equal to 18 inches; the Roman cubit equal to 1 foot 5, 406 inches; and the cubit of the ſcripture equal to 1 foot, 9, 888 inches.

CUCKOW, in ornithology. See Cuculus.

Cuckow-spit, the ſame with froth-ſpit. See Froth-spit.

Cuckow-spit-insect. See Cicada.

CUCUBALUS, in botany, a genus of the decandria trigynia claſs. The calix is inflated; the corolla has five petals with ungues; and the capſule has three cells. There are 13 ſpecies, five of which are natives of Britain, *viz.* the bacciferus, or berry-bearing chickweed; the beken, or white corn campion; the viſcoſus, or Dover campion; the olites, or Spaniſh catchfly; and the acaulis, or moſs campion.

CUCULUS, the Cuckow, in ornithology, a genus belonging to the order of picæ. The bill is ſomewhat cylindrical; the edges of the noſtrils are a little prominent; the tongue is arrow-ſhaped, plain, and not divided, and the toes are of the climbing kind, *i. e.* two before and two behind. It is about the ſize of a pigeon. The cuckow is a migrating bird; it comes to Britain about the end of April, hatches its young, and diſappears about St John's day. The cuckow neither builds a neſt, nor ſits upon its eggs; but takes poſſeſſion of a neſt built by ſmall birds of the ſparrow kind, in which it generally lays but one egg, which is hatched by the ſmall bird along with its own eggs; during the time of hatching, the cuckow ſits upon hedges or trees, and almoſt conſtantly ſings. If the cuckow's egg be firſt hatched, ſhe immediately throws out and deſtroys the eggs of the ſmall bird; but if the ſmall bird's eggs be firſt hatched, the cuckow allows the young to live till its own egg is hatched, and then deſtroys the young belonging to the ſmall bird. The ſmall bird feeds and brings up the young cuckow with as much care and attention as if it were its own, till it be able to procure its own food, when, ſome ſay, it ungratefully kills and eats its nurſe. The cuckow feeds upon caterpillars and ſmall birds; but is never tranſformed into a hawk, as is vulgarly ſuppoſed. It is a native of Europe. Linnæus enumerates no leſs than 22 ſpecies, which inhabit different parts of the globe, and are chiefly diſtinguiſhed by the ſhape of the tail and variations in colour.

CUCUMBER, in botany. See Cucumis.

CUCUMIS, or Cucumber, in botany, a genus of the monoecia ſyngeneſia claſs. The calix of the male has five teeth; the corolla is divided into five ſegments; and the filaments are three: The calix and corolla of the female are the ſame with thoſe of the male; the piſtillum is trifid; and the ſeeds of the apple are ſhort and ſlender. There are 11 ſpecies, none of them natives of Britain.

CUCURBIT, in chemiſtry. See Chemistry, Vol. II. p. 109.

CUCURBITA, the gourd, in botany, a genus of the monoecia ſyngeneſia claſs. The calix has five teeth; the corolla is divided into five ſegments; and the filaments are three: The calix and corolla of the female are the ſame with thoſe of the male; the piſtillum is quinquefid; and the ſeeds of the apple are turned at the edges. The ſpecies are five, none of them natives of Britain.

CUD ſometimes means the inſide of the throat in beaſts, and ſometimes the food that they keep there and chew over again: from whence, *to chew the cud*, ſignifies, to ponder, think, or ruminate upon a thing.

CUDWEED, in botany. See Gnaphalium.

CUENCA, a city and biſhop's ſee of New Caſtile, in Spain, about eighty-five miles eaſt of Madrid: W. long. 2° 40′, and N. lat. 40° 12′.

CUIRASSE, a piece of defenſive armour, made of iron plate, well hammered, ſerving to cover the body, from the neck to the girdle, both before and behind. Whence,

CUIRASSIERS, cavalry armed with cuiraſſes, as moſt of the Germans are: the French have a regiment of cuiraſſiers; but we have had none in the Britiſh army ſince the revolution.

CULDEES, in church-hiſtory, a ſort of monkiſh prieſts, formerly inhabiting Scotland and Ireland. Being remarkable for the religious exerciſes of preaching and praying, they were called, by way of eminence, *cultores Dei*; from whence is derived the word culdees. They made choice of one of their own fraternity to be their ſpiritual head, who was afterwards called the Scots biſhop.

CULEUS, in Roman antiquity, the largeſt meaſure of capacity for things liquid, containing twenty amphoræ, or forty urnæ. It contained one hundred forty-three gallons, three pints, Engliſh wine-meaſure; and was 11.095 ſolid inches.

CULEX, in zoology, a genus of inſects belonging to the order of diptera: The mouth is armed with ſetaceous prickles incloſed in a flexile ſheath. There are ſeven ſpecies, principally diſtinguiſhed by their colour.

CULIACAN, the capital of a province of the ſame name in Mexico, oppoſite to the ſouthern end of California: W. long. 113°, and N. lat. 24°.

CULLIAGE, a barbarous and immoral practice, whereby the lords of manors anciently aſſumed a right to the firſt night of their vaſſals brides.

CULLEN, a parliament town in Scotland, ſituated on the ſea-coaſt of Banffſhire: W. long. 2° 12′, and N. lat. 57° 38′.

CULM, or Culmus, among botaniſts. See Vol. I. p. 641.

CULMINATION, in aſtronomy, the paſſage of any heavenly body over the meridian, or its greateſt altitude for that day.

CULMORE, a town of Ireland, in the county of Londonderry, and province of Ulſter, about five miles north of Londonderry: W. long. 7° 40′, and N. lat 55°.

CULMUS. See CULM.

CULPRIT, a formal reply of a proper officer in court, in behalf of the king, after a criminal has pleaded not guilty, affirming him to be guilty, without which the iſſue to be tried is not joined.

The term culprit is a contraction of the Latin *culpabilis*, and the French *priſt;* importing that he is ready to prove the criminal guilty.

CULROSS, a parliament town of Scotland, ſituated on the river Forth, about twenty-three miles north-weſt of Edinburgh: W. long. 3° 34′, and N. lat. 56° 8′.

CULVERIN, in the military art, a large cannon, or piece of artillery; for the kinds, weight, and proportions of which, ſee CANNON.

CULVERTAILED, among ſhip-wrights, ſignifies the faſtening, or letting, of one timber into another, ſo that they cannot ſlip out, as the carlings into the beams of a ſhip.

CUMBERLAND, one of the moſt northerly counties of England, ſeparated from Scotland by the frith and river of Solway. It gives the title of duke to his royal highneſs William duke of Cumberland, *&c.*

CUMINOIDES, in botany. See LAGOECIA.

CUMINUM, in botany, a genus of the pentandria digynia claſs. The fruit is oval and ſtriated; it has four umbellulæ, and the involucrum conſiſts of four ſegments. There is but one ſpecies, a native of Egypt. The ſeeds are carminative and ſtomachic.

CUNEIFORM, in general, an appellation given to whatever reſembles a wedge.

CUNEIFORM BONE, in anatomy. See Vol. I. p. 180.

CUNEUS, the wedge, in mechanics. See MECHANICS.

CUNICULUS, in zoology. See LEPUS.

CUNILA, in botany, a genus of the diandria monogynia claſs; of which there are three ſpecies, none of them natives of Britain.

CUNNINGHAM, one of the four bailiwicks of Scotland, and one of the three into which the ſhire of Aire is ſubdivided. It lies north-eaſt of Kyle. Its chief town is Irwin.

CUP, among botaniſts, the ſame with calyx. See CALYX.

CUPANIA, in botany, a genus of the pentandria monogynia claſs. The calix conſiſts of three leaves; the ſtylus is trifid; the capſule has three valves; and the ſeeds are ſix. There is but one ſpecies, a native of America.

CUPOLA, in architecture, a ſpherical vault; or the round top of the dome of a church, in form of a cup inverted.

CUPPEL, or COPPEL, in chemiſtry. See COPPEL.

CUPPING, in ſurgery, the operation of applying cupping-glaſſes for the diſcharge of blood, and other humours, by the ſkin. See SURGERY.

CUPRESSUS, the CYPRESS-TREE, a genus of the monoecia monodelphia claſs. The calix of the male is a ſcale of the amentum; it has no corolla; and the antheræ have no filaments: The calix of the female is a ſtrobilus, and the ſquama contains a ſingle flower; it has no corolla; the ſtylus is a concave point; and the nut is angular. The ſpecies are four, none of them natives of Britain.

CUPRUM, or COPPER. See CHEMISTRY, Vol. II. p. 80.

CURASSOW, or CURAÇAO, one of the leſſer Antille-iſlands, ſubject to the Dutch, and ſituated in 68° 30′ W. long. and 12° 30′ N. lat.

CURATE, properly ſignifies the parſon or vicar of a pariſh, who has the charge or cure of the pariſhoners ſouls. See CURE.

CURATE, alſo ſignifies a perſon ſubſtituted by the incumbent, to ſerve his cure in his ſtead.

CURATOR, among civilians, a perſon regularly appointed to manage the affairs of minors, or perſons mad, deaf, dumb, *&c.* See LAW.

CURB, in the menage, a chain of iron, made faſt to the upper part of the branches of the bridle, in a hole called the eye, and running over the horſe's beard. It conſiſts of theſe three parts; the hook, fixed to the eye of the branch; the chain of SS's, or links; and the two rings, or mailes. Large curbs, provided they be round, are always moſt gentle: but care is to be taken, that it reſt in its proper place, a little above the beard, otherwiſe the bit-mouth will no have the effect that may be expected from it.

Engliſh watering bits have no curbs; the Turkiſh bits, called genettes, have a ring that ſerves inſtead of a curb. See GENETTES.

CURCULIO, in zoology, a genus of inſects belonging to the order of coleoptera. The feelers are ſubclavated, and reſt upon the ſnout, which is prominent and horny. There are no leſs than ninety-five ſpecies, principally diſtinguiſhed by their colour.

CURCUMA, or TURMERIC, in botany, a genus of the monandria monogynia claſs. It has four barren ſtamina, and only the fifth is fertile. There are two ſpecies, both natives of India. See Vol. I. p. 633.

CURDISTAN, a province of Perſia, having Turcomania, or Armenia, on the north, and Eyraca-Arabic, or Chaldea, on the ſouth.

CURDLING, the coagulating any fluid body, eſpecially milk.

It is ſaid, that at Florence they curdle their milk for the making of cheeſe with artichoke-flowers, inſtead of the rennet uſed among us for that purpoſe.

CURFEW, or COURFEW, a ſignal given in cities taken in war, *&c.* to the inhabitants to go to bed. Paſquin ſays, it was ſo called, as being intended to advertiſe the people to ſecure themſelves from the robberies and debaucheries of the night.

The moſt eminent curfew in England was that eſtabliſhed by William the Conqueror, who appointed, under

under ſevere penalties, that, at the ringing of a bell at eight o'clock in the evening, every one ſhould put out their lights and fires, and go to bed: whence, to this day, a bell rung about that time is called a curfew-bell.

CURIA, in Roman antiquity, a certain diviſion, or portion of a tribe. Romulus divided the people into thirty curiæ, or wards, whereof there were ten in every tribe, that each might keep the ceremonies of their feaſts and ſacrifices in the temple, or holy place, appointed for every curia. The prieſt of the curia was called curio.

CURIA, in the Engliſh law, generally ſignifies a court; and has been taken for the cuſtomary tenants, who do their ſuit and ſervice at the court of the lord. See COURT.

CURING, a term uſed for the preſerving fiſh, fleſh, and other animal ſubſtances, by means of certain additions of things, to prevent putrefaction. One great method of doing this, is by ſmoking the bodies with the ſmoke of wood, or rubbing them with ſalt, nitre, *&c.*

CURLEW, in ornithology. See SCOLOPAX.

CURNOCK, a meaſure of corn, containing four buſhels, or half a quarter.

CURRANS, or CURRANTS, the fruit of a ſpecies of groſſularia. See GROSSULARIA.

The white and red ſort are moſtly uſed; for the black, and chiefly the leaves, upon firſt coming out, are in uſe to flavour Engliſh ſpirits, and counterfeit French brandy. Currants greatly aſſuage drought, cool and fortify the ſtomach, and help digeſtion.

CURRANTS alſo ſignify a ſmaller kind of grapes brought principally from Zant and Cephalonia. They are gathered off the buſhes, and laid to dry in the ſun, and ſo put up in large butts. They are opening and pectoral, but are more uſed in the kitchen, than in medicine.

Currants, the hundred weight pay on exportation 1 l. 2s. $1\frac{35}{100}$d. and draw back on exportation 1 l. 0s. $7\frac{35}{100}$d. If imported in Venetian ſhips, they pay the 112 lb. 1 l. 3 s. $7\frac{35}{100}$d. and draw back 1 l. 1 s. $8\frac{85}{100}$d. In other foreign bottoms they pay 1 l. 7s. $4\frac{95}{100}$d. and draw back 1 l. 5 s. $6\frac{45}{100}$d.

CURRENT, in hydrography, a ſtream or flux of water in any direction. In the ſea, they are either natural, occaſioned by the diurnal motion of the earth round its axis, or accidental, cauſed by the waters being driven againſt promontories, or into gulfs and ſtreights, where, wanting room to ſpread, they are driven back, and thus diſturb the ordinary flux of the ſea. Dr Halley makes it highly probable that in the Downs, there are under-currents, by which as much water is carried out as is brought in by the upper-currents.

CURRENTS, in navigation, are certain ſettings of the ſtream, by which ſhips are compelled to alter their courſe or velocity, or both, and ſubmit to the motion impreſſed upon them by the current. See NAVIGATION.

CURRIERS, thoſe who dreſs and colour leather after it comes from the tan yard. See TANNING.

CURRUCU, in ornithology. See MOTACILLA.

CURRYING, the method of preparing leather with oil, tallow, *&c.* See TANNING.

CURTATE *diſtance*, in aſtronomy, the diſtance of a a planet from the ſun to that point where a perpendicular let fall from the planet meets with the ecliptic.

CURTATION, in aſtronomy, is the interval between a planet's diſtance from the ſun, and the curtate diſtance.

CURTIN, CURTAIN, or COURTIN, in fortification, is that part of the rampart of a place which is betwixt the flanks of two baſtions, bordered with a parapet five feet high, behind which the ſoldiers ſtand to fire upon the covered way and into the moat.

CURVATOR *coccygis*, in anatomy. See Vol. I. p. 220.

CURVATURE *of a line*, is the peculiar manner of its bending or flexure by which it becomes a curve of ſuch and ſuch peculiar properties.

CURVE, in geometry, a line which running on continually in all directions, may be cut by one right line in more points than one. See CONIC SECTIONS, and FLUCTIONS.

CURVET, or CORVET, in the menage, an air in which the horſe's legs are raiſed higher than in the demi volt; being a kind of leap up, and a little forwards, wherein the horſe raiſes both his fore-legs at once, equally advanced, (when he is going ſtraight forward, and not in a circle), and as his fore-legs are falling, he immediately raiſes his hind-legs, equally advanced, and not one before the other: ſo that all his four legs are in the air at once; and as he ſets them down, he marks but twice with them.

CURVILINEAR, or CURVILINEAL, is ſaid of figures bounded by curves, or crooked lines.

CURVIROSTRA, in ornithology. See LOXIA.

CURULE *chair*, in Roman antiquity, a chair adorned with ivory, wherein the great magiſtrates of Rome had a right to ſit and be carried.

The curule magiſtrates were the ædiles, the prætors, cenſors, and conſuls. This chair was fitted in a kind of chariot, whence it had its name. The ſenators who had borne the offices of ædiles, prætors, *&c.* were carried to the ſenate-houſe in this chair, as were alſo thoſe who triumphed, and ſuch as went to adminiſter juſtice, *&c.* See ÆDILE, *&c.*

CURZOLA, an iſland in the gulf of Venice, upon the coaſt of Dalmatia, about twelve miles from the iſland of Leſſina.

CUSCO, the capital city of Peru, during the reigns of the Incas: it is ſtill a fine city, and the ſee of a biſhop, and ſtands about 350 miles eaſt of Lima, in 70° W. long. and 13° S. lat.

CUSCUTA, or DODDER, a genus of the tetrandria digynia claſs. The calix conſiſts of four ſegments; the corolla has but one petal; and the capſule is bilocular. The are two ſpecies, one of which is a native of Britain, *viz.* the Europæa, dodder, hell-weed, or devil's-guts.

CUSPIDATED, in botany, are ſuch plants whoſe leaves are pointed like a ſpear.

CUSTOM,

CUSTOM, a very comprehenfive term, denoting the manners, ceremonies and fafhions of a people, which having turned into a habit, and paffed into ufe, obtains the force of laws; in which fenfe it implies fuch ufages, as, though voluntary at firft, are yet, by practice, become neceffary.

Cuftom is hence, both by lawyers and civilians, defined *lex non fcripta*, a law, or right, not written, eftablifhed by long ufage, and the confent of our anceftors: in which fenfe it ftands oppofed to the *lex fcripta*, or the written law.

CUSTOMS, in commerce, the tribute or toll, paid by merchants to the king, for goods exported or imported: they are otherwife called duties. See DUTY.

CUSTOM HOUSE, an office eftablifhed by the king's authority in the maritime cities, or port-towns, for the receipt and management of the cuftoms and duties of importation and exportation, impofed on merchandifes, and regulated by books of rates.

CUSTOS *brevium*, the principal clerk belonging to the court of common pleas, whofe bufinefs it is to receive and keep all the writs made returnable in that court, filing every return by itfelf; and, at the end of each term, to receive of the prothonotaries all the records of the nifi prius, called the pofteas.

CUSTOS *rotulorum*, an officer who has the cnftody of the rolls and records of the feffions of peace, and alfo of the commiffion of the peace itfelf.

He ufually is fome perfon of quality, and always a juftice of the peace, of the quorum, in the county where he is appointed.

CUSTOS *fpiritualium*, he that exercifes the fpiritual jurifdiction of a diocefe, during the vacancy of any fee, which, by the canon law, belongs to the dean and chapter; but at prefent, in England, to the archbifhop of the province, by prefcription.

CUSTOS *temporalium* was the perfon to whom a vacant fee or abbey was given by the king, as fupreme lord. His office was, as fteward of the goods and profits, to give an account to the efcheator, who did the like to the exchequer.

CUTAMBULI, certain worms, either under the fkin, or upon it, which, by their creeping, caufe an uneafy fenfation. It is alfo applied to wandering fcorbutic pains.

CUT-A-FEATHER, in the fea-language. If a fhip has too broad a bow, it is common to fay, *fhe will not cut a feather*; that is, fhe will not pafs through the water fo fwift, as to make it foam or froth.

CUTANEOUS, in general, an appellation given to whatever belongs to the cutis or fkin.

CUTICLE, in anatomy. See Vol. I. p. 285.

CUTICULAR, the fame with cutaneous.

CUTIS, the SKIN, in anatomy. See Vol. I. p. 254.

CUTTER *of the tallies*, an officer of the exchequer, whofe bufinefs is to provide wood for the tallies, to cut or notch the fum paid upon them; and then to caft them into court, to be written upon. See TALLY.

CUTTLE-FISH. See SEPIA.

CUZT, the moft eaftern province of the kingdom of Fez, in Africa.

CYANUS, in botany. See CENTAURIA.

CYATHUS, in Roman antiquity, a liquid meafure, containing four ligulas, or half a pint Englifh winemeafure, being $469\frac{2}{3}$ folid inches.

CYCLAMEN, or SOW-BREAD, in botany, a genus of the pentandria monogynia clafs. The corolla is rotated and reflected; the tube is very fhort, with a prominent faux; and the berry is covered with a capfule. There are two fpecies, none of them natives of Britain. The root is a powerful aperient and abftergent.

CYCLE. See Vol. I. p. 491.

CYCLE *of the moon*. See Vol. I. p. 491.

CYCLE *of the Roman indiction*. See Vol. I. p. 491.

CYCLISCUS, in furgery, an inftrument in the form of a half moon, ufed in fcraping the fkull, in cafe of fractures of that part.

CYCLOID, a curve on which the doctrine of pendulums and time-meafuring inftruments in a great meafure depend; Mr Huygens demonftrated, that from whatever point or height a heavy body, ofcillating on a fixed centre, begins to defcend, while it continues to move in a cycloid, the time of its falls or ofcillations will be equal to each other. It is likewife demonftrable, that it is the curve of quickeft defcent, *i. e.* a body falling in it, from any given point above, to another not exactly under it, will come to this point in a lefs time than in any other curve paffing through thofe two points.

CYCLOMETRY, a term fometimes ufed for the menfuration of circles.

CYCLOPÆDIA, or ENCYCLOPÆDIA, denotes the circle or compafs of arts and fciences. A cyclopædia, fay the authors of the French Encyclopædia, ought to explain, as much as poffible, the order and connection of human knowledge. See DICTIONARY.

CYCLOPTERUS, the LUMP-FISH, in ichthyology, a genus belonging to the order of amphibia nantes. The head is obtufe, and furnifhed with faw-teeth; there are four rays in the gills; and the belly-fins are connected together in an orbicular form. There are three fpecies.

CYDER, an excellent drink made of the juice of apples. It conduces greatly to the goodnefs of the cyder, to let the apples lie a week or two in heaps, before they are preffed. After ftraining the liquor through a fieve, let it ftand a day or two in an open tun, covered only with a cloth, or boards, to keep out the duft, that the more grofs parts may fubfide. Then draw it off in pails into veffels, wherein it is intended to be kept, obferving to leave an eighth part of them empty. Set thefe veffels in your coldeft cellars, with the bung open, or covered only with a loofe cover, both that the volatile fteams may have free vent, and that the muft may be kept cool, otherwife it is apt to ferment too much. Having fermentad in this manner for fifteen or twenty days, the veffel may be ftopped up clofe; and, in two or three months time, the cyder will be fit for drinking. But if you expect cyder in perfection, fo as to flower in the glafs, it muft be glued as they call it, and drawn off into bottles, after it has been a fhort time in the cafk: this is done by pouring into each vef-

fel

ſel a pint of the infuſion of ſixty or ſeventy grains of the moſt tranſparent iſing-glaſs, or fiſh-glue, in a little white-wine and river or rain water, ſtirred well together, after being ſtrained through a linen cloth. When this viſcous ſubſtance is put into the caſk, it ſpreads itſelf over the ſurface like a net, and carries all the dregs to the bottom with it.

Ginger added to cyder, not only corrects its windineſs, but makes it more briſk; and a few drops of currant-juice, beſides tinging, adds a pleaſant quickneſs to it. Honey, or ſugar, mixed with ſome ſpices, and added to flat cyder, will very much revive it.

Some commend boiling of cyder-juice, which ſhould be done as ſoon as it is preſſed, ſcumming it continually, and obſerving to let it boil no longer than till it acquires the colour of ſmall beer: when cold, put it into a caſk, leaving a ſmall vent; and when it begins to bubble up out of the vent, bottle it for uſe.

CYDONIA, in botany. See Crateva.

CYGNUS, in ornithology. See Anas.

Cygnus, in aſtronomy. See Vol. I. p. 486.

CYLINDER, in geometry, a ſolid body, ſuppoſed to be generated by the rotation of a parallelogram.

Rolling, or *loaded* Cylinder. See Mechanics.

CYLINDROID, in geometry, a ſolid body, approaching to the figure of a cylinder, but differing from it in ſome reſpect, as having the baſes elliptical, but parallel and equal.

CYLINDRUS, in natural hiſtory. See Voluta.

CYMA, in botany, the tender ſtalks which herbs ſend forth in the beginning of the ſpring, particularly thoſe of the cabbage-kind.

CYMATIUM, in architecture, a member or moulding, of the corniche, the profile of which is waved, that is, concave at top, and convex at bottom. See Architecture.

CYMBAL, a muſical inſtrument in uſe among the ancients. The cymbal was round, made of braſs, like our kettle-drums, and, as ſome think, in their form, but ſmaller, and of different uſe.

CYMBALARIA, in botany. See Antirrhinum.

CYMBARIA, in botany, a genus of the didynamia angioſpermia claſs of plants. The calix is divided into many parts; and the capſule is unilocular. There is but one ſpecies.

CYNÆDUS, in ichthyology. See Sparus.

CYNANCHE, among phyſicians, denotes an inflammation of the larynx.

CYNANCHUM, in botany, a genus of the pentandria digynia claſs. The nectarium is cylindrical, and has five teeth. There are five ſpecies, none of them natives of Britain.

CYNANTHROPIA, in medicine, the diſtemper occaſioned by the bite of a mad dog. See Medicine.

CYNAPIUM, in botany. See Ethusa.

CYNARA, the Artichoak, in botany, a genus of the ſyngeneſia polygamia æqualis claſs. The calix is dilated and imbricated, with fleſhy ſcales ſharp at the points. There are four ſpecies, none of them natives of Britain. The uſe of the artichoke as a food is well known.

CYNICS, a ſect of ancient philoſophers, who valued themſelves upon their contempt of riches and ſtate, arts and ſciences, and every thing, in ſhort, except virtue or morality.

The cynic philoſophers owe their origin and inſtitution to Antiſthenes of Athens, a diſciple of Socrates, who, being aſked of what uſe his philoſophy had been to him, replied, "It enables me to live with myſelf." Diogenes was the moſt famous of his diſciples, in whoſe life the ſyſtem of this philoſophy appears in its greateſt perfection: he led a moſt wretched life, a tub having ſerved him for a lodging, which he rolled before him where-ever he went; yet he was, nevertheleſs, not the more humble on account of his ragged cloak, bag, and tub; for, one day, entering Plato's houſe, at a time that there was a ſplendid entertainment there for ſeveral perſons of diſtinction, he jumped up upon a very rich couch, in all his dirt, ſaying, "I trample on the pride of Plato." "Yes (replied Plato,) but with great pride, Diogenes." He had the utmoſt contempt for all the human race, for he walked the ſtreets of Athens, at noon-day, with a lighted lantern in his hand, telling the people, "He was in ſearch of a man." Amongſt many excellent maxims of morality, he held ſome very pernicious opinions; for he uſed to ſay, that the uninterrupted good fortune of Harpalus, who generally paſſed for a thief and a robber, was a teſtimony againſt the gods. He regarded chaſtity and modeſty as weakneſſes; hence Laertius obſerves of him, that he did every thing openly, whether it belonged to Ceres or Venus, though he adds that Diogenes only ran to an exceſs of impudence to put others out of conceit with it: but impudence was the characteriſtic of theſe philoſophers, who argued, that what was right to be done, might be done at all times, and in all places. The chief principle of this ſect, in common with the ſtoics, was, that we ſhould follow nature; but they differed from the ſtoics in their explanation of that maxim, the cynics being of opinion that a man followed nature, that gratified his natural motions and appetites; while the ſtoics underſtood right reaſon, by the word nature.

Cynic spasm, a kind of convulſion, wherein the patient imitates the howlings of dogs.

CYNIPS, in zoology, a genus of inſects belonging to the order of hymenoptera. The mouth conſiſts of two jaws, without any proboſcis; and the ſting in the tail is ſpiral, and generally hid. There are nineteen ſpecies, diſtinguiſhed by their colour, and the plants they inhabit.

CYNOCEPHALUS, in zoology, the trivial name of a ſpecies of ſimia. See Simia.

CYNOGLOSSUM, in botany, a genus of the pentandria monogynia claſs. The corolla is tunnel-ſhaped; the ſeeds are depreſſed, and the ſtylus is fixed to the interior ſide of them. There are eight ſpecies, only one of which is a native of Britain, *viz.* the officinale, or hound's-tongue; the root is ſaid to be pectoral and narcotic.

CYNOMETRA, in botany, a genus of the decandria monogynia claſs. The calix conſiſts of four ſegments, the

the oppoſite ones being broader; and the legumen is fleſhy, lunated, and contains but one ſeed. There are two ſpecies, both natives of India.

CYNOMORIUM, in botany, a genus of the monoecia monandria claſs. The calix of the female is an imbricated amentum, and neither male nor female has a corolla; the female has one ſtylus, and one round ſeed. There is but one ſpecies, a native of Jamaica.

CYNOSURUS, in botany, a genus of the triandria dygínia claſs. The calix is a double valve, and includes many flowers. There are ten ſpecies, four of which are natives of Britain, *viz.* the criſtatus, or creſted dog-tail graſs; the echinatus, or rough dog-tail graſs; the cæruleus, or blue dog-tail graſs; and the paniceus, or bearded dog-tail graſs.

CYPERUS, in botany, a genus of the triandria monogynia claſs. The gluma is paleaceous and imbricated; it has no corolla, and but one naked ſeed. There are twenty ſpecies, only one of which is a native of Britain, *viz.* the longus, ſweet cyperus, or Engliſh galingale; the root is carminative and attenuant.

CYPHOMA, Cyphos, or Cyphosis, an incurvation of the ſpine, forming a crookedneſs in the back.

CYPRÆA, in zoology, a genus of inſects belonging to the order of vermes teſtacea. It is an animal of the limax or ſnail-kind; the ſhell is one involated, ſubovated, obtuſe, ſmooth valve. The aperture on each ſide is linear, longitudinal, and teethed. There are forty-four ſpecies, diſtinguiſhed by the form of their ſhells.

CYPRESS. See Cupressus.

CYPRINUS, in ichthyology, a genus of fiſhes belonging to the order of abdominales. The mouth is toothleſs; there are three rays in the gills; the body is ſmooth, and white; and the belly-fins have frequently nine rays. There are thirty-one ſpecies, principally diſtinguiſhed by the number of rays in the vent-fin.

CYPRIPEDIUM, in botany, a genus of the gynandria diandria claſs. The nectarium is ventricoſe, inflated, and hollow. There are two ſpecies, one of them, *viz.* the calceolus, or ladies-ſlipper, a native of Britain.

CYPRUS, an iſland ſituated in the moſt eaſterly part of the Levant, or Mediterranean ſea, between 33° and 36° E. long. and between 34° and 30° N. lat.

Knights of Cyprus, an order inſtituted by Guy de Luſignan, titular king of Jeruſalem, to whom Richard I. of England, after conquering this iſland, made over his right.

CYRENAICS, a ſect of ancient philoſophers, ſo called from their founder, *Ariſtippus* of Cyrene, a diſciple of Socrates.

The great principle of their doctrine was, that the ſupreme good of man in this life is pleaſure; whereby they not only meant a privation of pain, and a tranquillity of mind, but an aſſemblage of all mental and ſenſual pleaſures, particularly the laſt.

CYST, the bag, or tunic, including all incyſted tumors, as the ſcirrhus, atheroma, ſteotoma, meliceres, *&c.*

CYSTIC, a name given to two arteries and two veins. See Vol. I. p. 245.

Cystic duct. See Vol. I. p. 265.

CYTISUS, in botany, a genus of the diadelphia decandria claſs. The calix is bilabiated; and the legumen is attenuated at the baſe. There are eleven ſpecies, none of them natives of Britain.

CZACKATHURN, a town of Germany, in the dutchy of Stiria, and circle of Auſtria, ſituated near the conflux of the rivers Muer and Save, about fifty miles ſouth-eaſt of Gratz: E. long. 17°, and N. lat. 46° 50′.

CZAR, a title of honour aſſumed by the great dukes, or, as they are now ſtyled, emperors of Ruſſia.

Beckman makes no doubt but they took this title, by corruption, from Cæſar, emperor; and accordingly they bear an eagle, as the ſymbol of their empire, and the word Cæsar in their arms.

CZASLAW, a town of Bohemia, about thirty-five miles ſouth-eaſt of Prague: E. long. 15° 8′, and N. lat. 49° 50′.

CZERNIGOF, the capital of the province of Czernigof, in Ruſſia, near the frontiers of Poland: E. long. 31°, 30′, and N. lat. 52° 30′.

CZONGRODT, a town of Hungary, ſituated on the river Thieſſe, about thirty miles north of Segedin: E. long. 20° 45′, and N. lat. 46° 36′.

D

DAB, in ichthyology, the Engliſh name of a ſpecies of pleuronectes. See Pleuronectes.

DACA, a city of the province of Bengal, in the Eaſt-Indies, ſituated on a branch of the river Ganges: E. long. 89° and N. lat. 23° 30′.

DA CAPO, in muſic, ſignifies from the head or beginning; intimating, that the air is to be begun again, and ended with the firſt part.

DACE, the Engliſh name of a ſpecies of cyprinus. See Cyprinus.

DACOLITHUS, in ichthyology. See Cobitis.

DACTYL, in poetry, a metrical foot conſiſting of a long and two ſhort ſyllables, as *carmina, evident, excellence.*

The dactyl and ſpondee are the only feet or meaſures uſed in hexameter verſes. See Hexameter.

DACTYLIS, in botany, a genus of the triandria digynia claſs of plants. The calix conſiſts of two obtuſe valves, the one being ſomewhat larger than the other. The ſpecies are two, *viz.* the cynoſuroides, or

or ſmooth cock's-foot graſs; and the glomeratus, or rough cock's-foot graſs; both natives of Britain.

DACTYLUS, in zoology. See PHOLAS.

DADUCHI, in antiquity, prieſts of the goddeſs Ceres, ſo called, becauſe at the feaſts and ſacrifices of that goddeſs, they ran about the temple, carrying a lighted torch, which they delivered from hand to hand, till it had paſſed through them all. This they did in memory of Ceres's ſearching for her daughter Proſerpine, by the light of a torch, which ſhe kindled in mount Ætna.

DÆMON, a name given by the ancients to certain ſpirits, or genii, which appeared to men, either to do them ſervice, or to hurt them. The Platoniſts diſtinguiſh between gods, dæmons, and heroes. The gods are thoſe whom Cicero calls *Dii majorum gentium.* The dæmons are thoſe whom we call angels. Chriſtians, by the word dæmon, underſtand only evil ſpirits, or devils.

DÆMONIAC, a word applied to a perſon ſuppoſed to be poſſeſſed with an evil ſpirit, or dæmon. See DÆMON.

DÆMONIACS, in church-hiſtory, a branch of the anabaptiſts, whoſe diſtinguiſhing tenet is, that the devils ſhall be ſaved at the end of the world.

DAGO, or DAGERWORT, the capital of an iſland of the ſame name in the Baltic, near the coaſt of Livonia, ſubject to Ruſſia: E. long. 21° 30′, and N. lat. 58° 45′.

DAHGESTAN, a country of Aſia, bounded by Circaſſia on the north, by the Caſpian ſea on the Eaſt, by Chirvein a province of Perſia on the ſouth, and by Georgia on the weſt. Its chief towns are Tarku and Derbent, both ſituated on the Caſpian ſea.

DAHOME, a kingdom of Africa, on the Guinea coaſt.

DAISY. See BELLIS.

Great DAISY. See LEUCANTHEMUM.

Ox-eye DAISY. See BUPHTHALMUM.

DALEA, in botany. See PSORALEA.

DALEBURGH, the capital of the province of Dalia, in Sweden, ſituated on the weſtern ſide of the Wener-lake, fifty miles north-eaſt of Gottenburg; E. long. 13°, and N. lat. 59°.

DALECARLIA, a province of Sweden, abounding with iron and copper mines.

DALECHAMPIA, in botany, a genus of the monoecia monodelphia claſs. It has no corolla either in the male or female; and the ſeeds are roundiſh and ſolitary. There is but one ſpecies, *viz.* the ſcandens, a native of America.

DALKEITH, a town of Scotland, in the county of Lothian, ſix miles ſouth-eaſt of Edinburgh: W. long. 2° 40′, and N. lat. 55° 50′.

DALIA, a province of Sweden, bounded on the north by Dalecarlia, on the eaſt by Wermeland and the Wener-lake, on the ſouth by Gothland, and on the weſt by Norway.

DALMATIA, a frontier province of Europe, moſtly ſubject to the Turks, but ſome towns on the ſea-coaſt to the Venetians: it is bounded by Boſnia on the north, by Servia on the eaſt, by Albania on the ſouth, and by Morlachia and the gulph of Venice on the weſt.

DAMA, in zoology. See CERVUS.

DAMAGE, in law, is generally underſtood of a hurt, or hindrance attending a perſon's eſtate.

DAMALA, a ſea-port town of the Morea in Greece, at the entry of the gulf of Engea.

DAMAN, a port-town of the hither India, in the province of Guzurat or Cambay, ſituated on the weſt coaſt, about eighty miles ſouth of Surat, in 72° 20′ E. long. and 20° N. lat. It is ſubject to the Portugueſe.

DAMASCUS, or SCHAM, the capital city of the ſouth part of Syria, ſituated ninety miles north-eaſt of Jeruſalem, in a pleaſant, extenſive, and fruitful plain; E. long. 37° 20′, and N. lat. 33° 15′.

DAMASK, a ſilk-ſtuff, with a raiſed pattern, ſo as that the right ſide of the damaſk is that which hath the flowers raiſed or ſattined.

DAMASKEENING, or DAMASKING, the art or operation of beautifying iron, ſteel, *&c.* by making inciſions therein, and filling them up with gold and ſilver wire; chiefly uſed for adorning ſword-blades, guards and gripes, locks of piſtols, *&c.*

DAMASONIUM, in botany. See ALISONA.

DAMBEA, the capital of Abyſſinia, or Ethiopia, ſituated at the head of a lake, to which it gives name: E. long. 34°, and N. lat. 15°.

DAMELOPRE, a kind of bilander, uſed in Holland for conveying merchandize from one canal to another; being very commodious for paſſing under the bridges.

DAMIANISTS, in church-hiſtory, a branch of the ancient acephali-ſeveritæ. They agreed with the catholics in admitting the IVth council, but diſowned any diſtinctions of perſons in the Godhead; and profeſſed one ſingle nature, incapable of any difference; and yet they called God, the Father, Son, and Holy Ghoſt.

DAMIETTA, a port-town of Egypt, ſituated on the eaſtern mouth of the river Nile, four miles from the ſea, and 100 miles north of Grand Cairo; E. long. 32°, and N. lat. 31°.

DAMNATA TERRA, among chemiſts, the ſame with caput mortuum. See CAPUT.

DAMPS, in natural hiſtory, noxious ſteams and exhalations, frequently found in mines, pits, wells, and other ſubterraneous places. See PNEUMATICS.

DAMSEL, from the French *damoiſel*, or *damoiſeau*, an appellation anciently given to all young people of either ſex, that were of noble or genteel extraction, as the ſons and daughters of princes, knights, and barons: thus we read of Damſel Pepin, Damſel Louis le Gros, Damſel Richard prince of Wales.

From the ſons of kings this appellation firſt paſſed to thoſe of great lords and barons, and at length to thoſe of gentlemen, who were not yet knights.

At preſent, damſel is applied to all maids or girls, not yet married, provided they be not of the vulgar.

DANAE, in antiquity, a coin ſomewhat more than an obolus, uſed to be put into the mouths of the dead, to pay their paſſage over the river Acheron.

DANCE, an agreeable motion of the body, adjuſted by art to the meaſures or tune of inſtruments, or of the voice.

Athenæus concludes, that in the early ages of antiquity, they accounted dancing an exerciſe becoming perſons of honour and wiſdom; and that, as ſuch, it had been eſteemed by the greateſt men in all ages. Thus, Homer calls Merion a fine dancer; and ſays, that the graceful mein and great agility which he had acquired by that exerciſe, diſtinguiſhed him above the reſt in the armies of either Greeks or Trojans. Dancing was in very great eſteem among the Greeks, even the Lacedemonians encouraged it: but, at Rome, we find the cuſtom was quite otherwiſe; for there, to uſe the words of Cicero, no man dances unleſs he is mad or drunk: Cicero reproaches Gabinius with having danced: and we read, that Domitian excluded ſeveral members from the ſenate for having danced.

Dancing in general, was by the ancients divided into cubiſtic, ſpheriſtic, and orcheſtic: the cubiſtic dance was performed with certain wreſtlings and contorſions of the body; the ſpheriſtic with a ſort of ball, or bowl play; but the orcheſtic was moſt uſual, and what indeed was dancing properly ſo called.

Dancing is uſually an effect and indication of joy; though Mr Palleprat aſſures us, that there are nations in South America, who dance to ſhew their ſorrow. It has been in uſe among all nations, civilized and barbarous; though held in eſteem among ſome, and in contempt among others. It has often been, and ſtill is, ſometimes made an act of religion. Thus David danced before the ark to honour God, and expreſs his exceſs of joy for its return into Sion. Among the pagans it made a part of the worſhip paid to the gods, it being uſual to dance round the altars and ſtatues; and at Rome, the ſalii, who were prieſts of Mars, danced through the ſtreets in honour of that God. The poets made the gods themſelves dance. The Chriſtians are not free from this ſuperſtition; for in popiſh countries certain feſtivals, particularly thoſe of the ſacrament, and paſſion of our Lord, are celebrated with dancing.

DANCETTE, in heraldry, is when the outline of any bordure, or ordinary, is indented very largely, the largeneſs of the indentures being the only thing that diſtinguiſhes it from indented.

DANDELION, in botany. See LEONTODON.

DANEGELT, a tax or tribute on every hide of land, impoſed on our anceſtors the Saxons by the Danes, on their frequent invaſions, as the arbitrary terms of peace and departure.

DARNAMAS, the name of the beſt ſort of cotton that comes from Smyrna, ſo called from a plain near that city.

DANTELLE, in heraldry. See DANCETTE.

DANTIA, in botany. See ISNARDIA.

DANTZICK, the capital of regal Pruſſia, in the kingdom of Poland, ſituated on the weſtern ſhore of the river Weſel, or Viſtula, which a little below falls into the Baltic ſea: E. long. 19°, and N. lat. 54°. It is an excellent harbour, and has the beſt foreign trade within the Baltic.

DANUBE, one of the largeſt rivers in Europe, which, taking its riſe in the Black Foreſt in Swabia, runs eaſtward through Bavaria, Auſtria, Hungary, and Turky in Europe; diſcharging itſelf by ſeveral channels into the Pontus Euxinus, or Black Sea.

DAPHNE, in botany, a genus of the octandria monogynia claſs. It has no calix; the corolla conſiſts of four ſegments; and the berry contains but one ſeed. There are 11 ſpecies, two of which are natives of Britain, *viz.* the laureola, or ſpurge laurel; and the mezereum, or ſpurge olive. The laureola is a ſtrong cathartic.

DAPPLE BAY, in the menage: when bay horſes have marks of a dark bay, they are called dapple-bays.

DAPPLE-BLACK; when a black horſe has got ſpots or marks, more black or ſhining than the reſt of his ſkin, he is called a dapple-black.

DARAPTI, among logicians, one of the modes of ſyllogiſms of the third figure, whoſe premiſes are univerſal affirmatives, and the concluſion is a particular affirmative: thus,

DAR- Every body is diviſible;
AP- Every body is a ſubſtance;
TI, Therefore, ſome ſubſtance is diviſible.

DARBY, the capital of Darbyſhire, ſituated on the river Darwent: W. long. 1° 25′, and N. lat. 53°.

DARDANELLS, two caſtles at the entrance of the Helleſpont, where all ſhips going to Conſtantinople are examined: E. long. 27°, and N. lat. 40° 5′.

DARIEN, a province of Terra Firma, in South America, being the narrow iſthmus which joins North and South America.

DARII, in logic, one of the modes of ſyllogiſm of the firſt figure, wherein the major propoſition is an univerſal affirmative, and the minor and concluſion particular affirmatives: thus,

DA- Every thing that is moved, is moved by another;
RI- Some body is moved;
I. Therefore, ſome body is moved by another.

DARKING, a market-town of Surrey, ſituated ten miles eaſt of Guilford: W. long. 20′, and N. lat. 51° 18′.

DARLINGTON, a market-town of the county of Durham, ſituated twenty miles ſouth of the city of Durham: W. long. 1° 15′, and N. lat. 54° 30′.

DARMSTAT, the capital of Heſſe-Darmſtat, in the circle of the upper Rhine in Germany, ſituated on a river of the ſame name, fourteen miles ſouth of Francfort, and thirteen ſouth-eaſt of Mentz: E. long. 8° 25′, and N. lat. 49° 45′.

DARNEL, in botany. See LOLIUM.

DARTFORD, a market-town of Kent, in the Dover-road, fourteen miles ſouth-eaſt of London: E. long. 16′, and N. lat. 51° 25′.

DARTMOUTH, a borough and port town of Devonſhire, ſituated on the Engliſh channel, twenty-ſix miles

ſouth

fouth of Exeter, which fends two members to parliament: W. long. 4°, and N. lat. 50° 25′.

DARWENT, a river, which, rifing in the Peak of Darbyfhire, runs from north to fouth through that county, and falls into the Trent.

DASYPUS, the ARMADILLO, in zoology, a genus of quadrupeds belonging to the order of bruta. The dafypus has neither fore-teeth nor dog-teeth; it is covered with a hard boney fhell, interfected with diftinct moveable zones or belts: This fhell covers the head, the neck, the back, the flanks, and extends even to the extremity of the tail; the only parts to which it does not extend, are the throat, the breaft, and the belly, which are covered with a whitifh fkin of a coarfe grain, refembling that of a hen after the feathers are pulled off. The fhell does not confift of one entire piece, like that of the tortoife, but is divided into feparate belts connected to each other by membranes, which enable the animal to move it, and even to roll itfelf up like a hedge-hog. The number of thefe belts does not depend on the age of the animal, as fome have imagined, but is uniformly the fame at all times, and ferves to diftinguifh the different fpecies. All the fpecies of this animal were originally natives of America: they were entirely unknown to the ancients; and modern travellers mention them as peculiar to Mexico, Brafil, and the fouthern parts of America; though fome indeed have confounded them with two fpecies of manis, or fhell lizard, which are found in the Eaft Indies: Others report that they are natives of Africa, becaufe fome of them have been tranfported from Brafil to the coaft of Guinea, where a few have fince been propagated: but they were never heard of in Europe, Afia, or Africa, till after the difcovery of America. — They are all endowed with the faculty of extending and contracting their bodies, and of rolling themfelves up like a ball, but not into fo compleat a fphere as the hedge-hog. They are very inoffenfive animals, excepting when they get into gardens, where they devour the melons, potatoes, and other roots. They walk quickly; but can hardly be faid to run or leap; fo that they feldom efcape the purfuit either of men or dogs. But nature has not left them altogether defencelefs. They dig deep holes in the earth; and feldom go very far from their fubterraneous habitations: Upon any alarm, they immediately go into their holes; but, when at too great a diftance, they require but a few moments to make one. The hunters can hardly catch them by the tail before they fink their body in the ground, where they ftick fo clofe, that the tail frequently comes away and leaves the body in the earth; which obliges the hunters, when they want to take them alive and immutilated, to dilate the fides of the hole. When they are taken, and find that there is no refource, they inftantly roll themfelves up, and will not extend their bodies, unlefs they are held near a fire. When in deep holes, there is no other method of making them come out, but by forcing in fmoke or water. They keep in their holes through the day, and feldom go abroad in queft of fubfiftence but in the night. The hunters ufually chafe them with fmall dogs, which eafily come up with them. When the dogs are near, the creatures inftantly roll themfelves up, and in this condition the hunters carry them off. However, if they be near a precipice, they often efcape both the dogs and hunters: they roll themfelves up, and tumble down like a ball, without breaking their fhell, or receiving any injury. The dafypus is a very fruitful animal; the female generally brings forth four young ones every month; which is the reafon why the fpecies is fo numerous, notwithftanding they are fo much fought after on account of the fweetnefs of their flefh. The Indians likewife make bafkets, boxes, &c. of the fhells which cover their heads.

Linnæus enumerates fix fpecies of dafypus, principally diftinguifhed by the number of their moveable belts.

1. The novemcinctus, or dafypus, with nine moveable belts, (fee Plate LXVIII. fig. 1.) The head is long and narrow; the muzzle extends a good way beyond the under lip; the mouth is large; the eyes are fmall, and placed on the fides of the head; the ears are long, and placed near each other; the tail is long and conical, and terminates in a fharp point. It has five toes on the hind-feet, and only four on the fore-feet; the claws are long, and of a yellowifh colour. The length of the body, from the point of the muzzle, to the origin of the tail, is about eleven inches; and the length of the tail, about nine and a half.

2. The unicinctus, or dafypus, with eighteen moveable belts: the other fpecies have two large immoveable pieces of fhell, one on the fhoulders, and another on the buttocks: this fpecies has but one, which is on the fhoulders, from that to the tail confifting entirely of moveable belts. The length of the body, from the point of the muzzle, to the origin of the tail, is about nine inches, and the tail about five.

3. The tricinctus, or dafypus, with three moveable belts. The head is oblong, and covered with an entire piece of fhell; the ears are fhort and roundifh; it has five toes on all the feet, and the two middle claws of the fore-feet are remarkably larger than the reft; the tail is fhort, being about two inches in length; and the body is about one foot long.

4. The quadricinctus, or dafypus, with four moveable belts: Linnæus is miftaken with regard to the trivial name and fpecific character of this animal; it ought to be called the fexcinctus, or dafypus, with fix moveable belts; for, according to Briffonius, Bouffon, and moft other natural hiftorians, none of the fpecies of this genus have four moveable belts. It has five toes on every foot.

5. The feptemcinctus, or dafypus, with feven moveable belts: Here Linnæus is in another error of the fame kind; for this animal has eight moveable belts. It has four toes on the fore-feet, and five on the hind-feet.

6. The dafypus with 12 moveable belts. This is the largeft fpecies, being about two feet in length.

DATA, among mathematicians, a term for fuch things or quantities as are given or known, in order to find other things thereby that are unknown. Euclid ufes the word data (of which he hath a particular tract) for

for ſuch ſpaces, lines, and angles as are given in magnitude, or to which we can aſſign others equal.

DATE, in law, is the deſcription of the day, month, year of our Lord, and year of the reign of the king, in which a deed or other writing was made.

DATE, the fruit of the phœnix, or great palm-tree. See PHOENIX.

DATISI, in logic, a mode of ſyllogiſms in the third figure, wherein the major is an univerſal affirmative, and the minor and concluſion particular affirmative propoſitions. For example,

DA- All who ſerve God are kings;
TI- Some who ſerve God are poor;
SI. Therefore, ſome who are poor are kings.

DATIVE, among grammarians, the third caſe in the declenſion of nouns, expreſſing the relation of a thing to whoſe profit or loſs ſome other thing is referred. It is called dative, becauſe uſually governed by a verb, implying ſomething to be given to ſome perſon. In Engliſh, the dative is expreſſed by the ſigns *to* or *for*.

DATURA, the THORN-APPLE, in botany, a genus of the pentandria monogynia claſs. The corolla is plaited and tunnel-ſhaped; the calix is tubulous, angular, and deciduous; and the capſule conſiſts of four valves. There are ſix ſpecies, all natives of warm climates. The thorn-apple is a narcotic poiſon: It has lately been recommended in caſes of madneſs by Dr Stork, but without anſwering any uſeful purpoſe.

DAUCUS, the CARROT, in botany, a genus of plants belonging to the pentandria digynia claſs. The corollæ are ſubradiated, and all hermaphrodite; and the ſeeds are rough and hairy. There are five ſpecies, only one of which, *viz.* the carota, wild-carrot, or bird's-neſt, is a native of Britain. The ſeeds are ſaid to be diuretic and carminative.

DAVENTRY, a market-town of Northamptonſhire, ſituated about ten miles north of Northampton: W. long. 1° 15′, and N. lat. 52° 12′.

DAVIDISTS, in church-hiſtory, a ſect of Chriſtian heretics in the XVIth century; ſo called from David George, their leader, who began by giving out that he was the Meſſiah, and was ſent into the world in order to people the kingdom of heaven, which was quite empty of inhabitants, for want of virtuous and good men: he rejected marriage, and denied the reſurrection.

DAVIDS, or ST DAVID's, a city and biſhop's ſee of Pembrokeſhire, ſituated near the Iriſh channel, about twenty miles north-weſt of Pembroke: W. long. 5° 20′, and N. lat. 52°.

ST DAVID's is alſo the name of a town and fort ſituated on the coaſt of Coromandel, in the hither India, about eighty miles ſouth of Fort St George: E. long. 79° 40′, and N. lat. 11° 45′.

DAVIS's STRAITS run north-weſt from Cape Farewell, in 60° N. lat. to Baffin's bay, in 80° N. lat. ſeparating Greenland from North America.

DAVIT, in a ſhip, that ſhort piece of timber with a notch at one end, wherein, by a ſtrap, hangs the fiſh-block.

The uſe of this block is to help up the fluke of the anchor, and to faſten it at the ſhip's bow or loof. The davit is ſhiftable from one ſide of the ſhip to the other, as there is occaſion.

DAUPHIN, a title given to the eldeſt ſon of France, and heir preſumptive of the crown, on account of the province of Dauphiny, which, in 1343, was given to Philip of Valois, on this condition, by Humbert dauphin of the Viennois.

DAUPHIN-FORT, a fort built by the French, on the eaſtern coaſt of the iſland of Madagaſcar, E. long. 48°, and S. lat. 24°.

DAUPHINE, or DAUPHINY, a province of France, bounded by Burgundy on the north, by Piedmont on the eaſt, by Provence on the ſouth, and by the river Rhone, which ſeparates it from Languedoc and the Lyonois, on the weſt.

DAY. See Vol. I. p. 491.

DAYS *of grace*, are thoſe granted by the court at the prayer of the defendant, or plaintiff, in whoſe delay it is.

DAYS *of grace*, in commerce, are a cuſtomary number of days allowed for the payment of a bill of exchange, *&c.* after the ſame becomes due.

Three days of grace are allowed in Britain; ten in France and Dantzic; eight at Naples; ſix at Venice, Amſterdam, Rotterdam, and Antwerp; four at Francfort; five at Leipſic; twelve at Hamburg; ſix in Portugal; fourteen in Spain; thirty in Genoa, *&c.*

DAY's MAN, in the north of England, an arbitrator or perſon choſen to determine an affair in diſpute.

Intercalary DAYS. See Vol. I. p. 489.

DEACON, one of the three ſacred orders of the Chriſtian church.

As to the office of deacons, the moſt common and ordinary was to be attendant on the biſhops and preſbyters in the ſervice of the altar, to take care of the holy table and all the ornaments and utenſils belonging to it; and, in the next place, to receive the offerings of the people, and to preſent them to the prieſt; at the ſame time reciting the names of thoſe that offered. In ſome churches, though not in all, the deacons read the goſpel both before and at the communion-ſervice; but their moſt peculiar office was to aſſiſt the biſhop and preſbyters in the adminiſtration of the euchariſt, at which their buſineſs was to diſtribute the elements to the people who were preſent, and carry them to thoſe who were abſent. That they were never allowed to conſecrate them at the altar, appears from the teſtimonies of Hilary, Jerom, and the author of the conſtitutions. They were permitted, however, to adminiſter ſolely the ſacrament of baptiſm in ſome caſes. Another part of the office of deacons, was to be a ſort of monitors and directors to the people in the exerciſe of their public devotions in the church; for which purpoſe they made uſe of certain known forms of words, to give notice when each part of the ſervice began. Whence they are ſometimes called [*eirokerukes*,] the the holy cryers of the church.

Deacons had, by licence and authority from the biſhop, a power to preach, to reconcile penitents and grant them abſolution, and to repreſent their biſhops in

in general councils. Their office out of the church was to take care of the neceſſitous, ſuch as orphans, widows, priſoners, and all the poor and ſick who had any title to be maintained out of the public revenues of the church; to inquire into the morals and converſation of the people, and to make their report thereof to the biſhop. Whence, on account of the variety of buſineſs, it was uſual to have ſeveral deacons in the ſame church.

In the Romiſh church, it is the deacons office to incenſe the officiating prieſt or prelate; to lay the corporal on the altar; to receive the paten or cup from the ſubdeacon, and preſent them to the perſon officiating; to incenſe the choir; to receive the pax from the officiating prelate, and carry it to the ſubdeacon; and at the pontifical maſs, when the biſhop gives the bleſſing, to put the mitre on his head, and to take off the archbiſhop's pall, and lay it on the altar. In England, the form of ordaining deacons, declares that it is their office to aſſiſt the prieſt in the diſtribution of the holy communion; in which, agreeably to the practice of the ancient church, they are confined to the adminiſtering the wine to the communicants. A deacon, with us, is not capable of any eccleſiaſtical promotion, yet he may be a chaplain to a family, curate to a beneficed clergyman, or lecturer to a pariſh church. He may be ordained at twenty-three years of age, *anno currente*; but it is expreſsly provided, that the biſhop ſhall not ordain the ſame perſon a prieſt and deacon in the ſame day. Deacons according to St Paul, ſhould be chaſte, ſincere, and blameleſs; neither great drinkers, nor given to filthy lucre; they ſhould hold the myſtery of the faith in a pure conſcience, and ſhould be well approved before they are admitted to the miniſtry.

DEACONESS, *a female deacon*, an order of women, who had their diſtinct offices and ſervices in the primitive church. This office appears as ancient as the apoſtolical age; for St Paul calls Phebe a ſervant of the church of Cenchrea. The original word is [*diakonos*], anſwerable to the Latin word *miniſtra*. Tertullian calls them *viduæ*, widows, becauſe they were commonly choſen out of the widows of the church; and, for the ſame reaſon, Epiphanius, when the council of Laodicea, calls them [*preſbutidas*], elderly women, becauſe none but ſuch were ordinarily taken into this office. For, indeed, by ſome ancient laws, theſe four qualifications were required in every one that was to be admitted into this order. 1. That ſhe ſhould be a widow. 2. That ſhe ſhould be a widow that had born children. 3. A widow that was but once married. 4. One of a conſiderable age, forty, fifty, or ſixty years old. Though all theſe rules admitted of exceptions. Concerning their ordination, whether it was always performed by impoſition of hands, the learned are much divided in their ſentiments. Baronius and Valeſius think they were not, and make no other account of them than as mere lay-perſons. But the author of the conſtitutions, ſpeaking of their ordination, requires the biſhop to uſe impoſition of hands, with a form of prayer which is there recited. We are not, however, to imagine, that this ordination gave them any power to execute any part of the ſacerdotal office. They were only to perform ſome inferior ſervices of the church, and thoſe chiefly relating to the women for whoſe ſakes they were ordained. One part of their office was to aſſiſt the miniſter at the baptizing of women, to undreſs them for immerſion, and to dreſs them again, that the whole ceremony might be performed with all the decency becoming ſo ſacred an action. Another part of their office was to be private catechiſts to the women-catechumens who were preparing for baptiſm. They were likewiſe to viſit and attend women that were ſick and in diſtreſs; to miniſter to the martyrs and confeſſors in priſon; to attend the womens gate in the church; and, laſtly, to aſſign all women their places in the church, regulate their behaviour, and preſide over the reſt of the widows, whence in ſome canons they are ſtyled [*prokathemenai*] governeſſes. This order, which ſince the tenth or twelfth century has been wholly laid aſide, was not aboliſhed every where at once, but continued in the Greek church longer than in the Latin, and in ſome of the Latin churches longer than in others.

DEAD-MAN's HEAD, in geography, a cape or promontory near Tregony in Cornwall, between St Mawes and Fowey.

DEAD-MENS-EYES, in the ſea-language, a kind of blocks with many holes in them, but no ſheevers, whereby the ſhrowds are faſtened to the chains: the crow-feet reeve alſo through theſe holes; and, in ſome ſhips, the main-ſtays are ſet tight in them; but then they have only one hole, through which the lanyards are paſſed ſeveral times.

DEAD-NETTLE. See LAMIUM.

DEAD-RECKONING, in navigation, the calculation made of a ſhip's place by means of the compaſs and log; the firſt ſerving to point out the courſe ſhe ſails on, and the other the diſtance run. See NAVIGATION.

DEAD's PART, in Scots law, that proportion of the funds of a marriage, which, upon the diſſolution of it, goes to the executor of the deceaſed huſband or wife, as the defunct or dead's part. See SCOTS LAW, title 28.

DEAD-SEA, in geography, a lake of Judea, into which the river Jordan diſcharges itſelf; being about ſeventy miles long, and twenty broad.

DEAD-TOPS, a diſeaſe incident to young trees, and cured by cutting off the dead parts cloſe to the next good twig or ſhoot, and claying them over as in grafting.

DEAD-WATER, at ſea, the eddy-water juſt aſtern of a ſhip, ſo called, becauſe it does not paſs away ſo ſwift as the water running by her ſides does They ſay that a ſhip makes much dead-water, when ſhe has a great eddy following her ſtern.

DEADLY CARROT. See THAPSIA.

DEADLY NIGHTSHADE. See ATROPA.

DEADS, among miners, denotes the earth or other foſſile ſubſtances which incloſe the ore on every ſide. Hence, *breaking up the deads*, is the removing theſe ſubſtances for the conveniency of carrying on their work.

DEAFNESS,

DEAFNESS, the ſtate of a perſon who either wants the ſenſe of hearing, or has it greatly impaired. See DUMB.

DEAL, a thin kind of fir-planks, of great uſe in carpentry: they are formed by ſawing the trunk of a tree into a great many longitudinal diviſions, of more or leſs thickneſs, according to the purpoſes they are intended to ſerve.

Deals are rendered much harder, by throwing them into ſalt water as ſoon as they are ſawed, keeping them there three or four days, and afterwards drying them in the air or ſun; but neither this nor any other method yet known, will preſerve them from ſhrinking.

Deals called Burgendorp deals, the hundred containing ſix ſcore, pay on importation 3 l. 8 s. $8\frac{40}{100}$ d. and draw back 3 l. 3 s. the rate 12 l. Meabro deals, ſix ſcore, pay 1 l. 2 s. $10\frac{80}{100}$ d. and draw back 1 l. 1s. the rate 4 l. Norway deals, ſix ſcore, pay 1 l. 8 s. $7\frac{1}{2}$ d. and draw back 1 l. 6 s. 3 d. the rate 5 l. Spruce deals, ſix ſcore, pay 4 l. 5 s. $10\frac{1}{2}$ d. and draw back 3 l. 18 s. 9 d. the rate 15 l. Deals from Ruſſia, and all other countries not particularly rated, exceeding twenty foot in length, pay 4 l. 5 s. $10\frac{50}{100}$ d. and draw dack 3 l. 18 s. 9 d. the rate 15 l. Deals from Sweden, or any other country, of twenty feet in length or under, not otherwiſe rated, the 120, pay 1 l. 8 s. $7\frac{1}{2}$d. and draw back 1 l. 6 s. 3 d. the rate 5 l.

DEAL, in geography, a port-town of the county of Kent, between which and the Goodwin-ſands, the ſhipping uſually rides in the Downs, in going out or coming home: it is about ſixty-ſeven miles eaſtward of London: E. long. 1° 30′, and N. lat. 51° 16′.

DEAN, an eccleſiaſtical dignitary in cathedral and collegiate churches, and head of the chapter.

DEAN *and* CHAPTER, are the biſhop's council to aſſiſt him in the affairs of religion, and to aſſent to every grant which the biſhop ſhall make to bind his ſucceſſors. As a deanry is a ſpiritual dignity, a man cannot be a dean and prebendary of the ſame church.

DEAN *of guild*, in Scots law, a magiſtrate of a royal borough, who has the cognizance of mercantile cauſes, and the inſpection of buildings within borough. See SCOTS LAW, title 4.

DEATH is generally conſidered as the ſeparation of the ſoul and body; in which ſenſe it ſtands oppoſed to life, which conſiſts in the union thereof.

The law of DEATH-BED, in Scots law, the privilege which that law allows to an heir of reducing all deeds reſpecting the heretable eſtate of his predeceſſor, granted by him while on death-bed, in prejudice of the lawful heir. All deeds are liable to reduction *ex capite lecti*, that are granted by a perſon within ſixty days of his death, if he had then contracted the diſeaſe of which he died, and had not afterwards recovered, ſo as to have gone to kirk or market unſupported. See SCOTS LAW, title 27.

DEBENHAM, a market-town of Suffolk, about twenty miles eaſt of Bury: E. long. 1° 20′, and N. lat. 52° 20′.

DEBENTURE, a term of trade uſed at the cuſtom-houſe for a kind of certificate ſigned by the officers of the cuſtoms, which intitles a merchant exporting goods to the receipt of a bounty or draw-back. All merchandiſes that are deſigned to be taken on board for that voyage being entered and ſhipped, and the ſhip being regularly cleared out, and ſailed out of port on her intended voyage, debentures may be made out from the exporter's entries, in order to obtain the drawbacks, allowances, bounties, or premiums; which debentures for foreign goods are to be paid within one month after demand. And in making out theſe debentures, it muſt be obſerved, that every piece of vellum, parchment, or paper, containing any debenture for drawing back cuſtoms or duties, muſt, before writing, be ſtamped, and pay a duty of 8 d.

The forms of debentures vary, according to the merchandiſe exported. In the execution of debentures for tobacco, it muſt be particularly obſerved, 1. That debentures for the ſame quantity, may be made in one or more parchments. 2. That the exporter's oath muſt be printed, ſpecifying whether he acts for himſelf or by commiſſion. If exported to any other foreign ports than Ireland, the word *Ireland* muſt be added to the oath after Great Britain. 4. That as no tobacco may be conſumed on board ſhips of war in Europe, but what has paid full duties, and been manufactured in Great Britain, no drawback is to be allowed for tobacco exported in any man of war. 5. That the eight pounds *per* hogſhead of 350 pounds, or more, allowed for draught at importation, muſt not be deducted on exportation. 6. That debentures for tobacco exported to Ireland, muſt not be paid till a certificate be produced, teſtifying the landing thereof. 7. That no perſons may ſwear to the exportation, but ſuch as are permitted to ſwear to debentures for other goods. In debentures for all other foreign goods, no perſon may be admitted to ſwear to the exportation, but the true exporter, either as a proprietor, or who being employed by commiſſion, is concerned in the direction of the voyage. All kinds of debentures before delivered or paid to the exporters, are entered into a ſeparate book kept for that purpoſe by the collector and comptroller of the cuſtoms.

DEBITA *fundi*, in Scots Law. A debt is ſaid to be a *debitum fundi*, when it is recoverable either by a perſonal action againſt the debtor himſelf, or by a real action againſt his lands.

DEBITA *fructuum*, in Scots law. Funds are *debita fructuum* not *fundi*; ſo are not recoverable out of the lands themſelves, but out of the fruits of the lands out of which they are payable. See SCOTS LAW, title 17.

DEBILITY, among phyſicians, a relaxation of the ſolids, occaſioning oftentimes weakneſſes and faintings.

DEBRECHEN, a town of Upper Hungary, about ſeventy-ſeven miles eaſt of Buda: E. long. 21° 10′ N. lat. 47° 45′.

DEBRUIZED, in heraldry, a term peculiar to the Engliſh, by which is intimated the grievous reſtraint of any animal, debarred of its natural freedom, by any of the ordinaries being laid over it.

DEBT, in law, any thing due to another, whether it be

money,

money, goods, or ſervices; or the action brought for recovering the ſame.

DEBTOR, a perſon who owes any thing to another; in contradiſtinction to creditor, which is he to whom the debt is owing.

DEBTOR, in merchants accounts. See BOOK-KEEPING.

DECAGON, in geometry, a plane figure with ten ſides and ten angles.

DECALOGUE, the ten precepts or commandments delivered by God to Moſes, after engraving them on two tables of ſtone.

The Jews, by way of excellence, call theſe commandments the *ten words*, from whence they had afterwards the name of decalogue: but it is to be obſerved, that they joined the firſt and ſecond into one, and divided the laſt into two: they underſtand that againſt ſtealing, to relate to the ſtealing of men, or kidnapping; alledging, that the ſtealing one anothers goods or property, is forbidden in the laſt commandment.

The emperor Julian objected to the decalogue, that the precepts it contained (thoſe only excepted which concern the worſhip of falſe gods, and the obſervation of the ſabbath) were already ſo familiar to all nations, and ſo univerſally received, that they were unworthy, for that very reaſon, to be delivered, by ſo great a legiſlator, to ſo peculiar a people. The church of Rome has ſtruck the ſecond commandment quite out of the decalogue, and to make their number complete, hath ſplit the tenth into two. The reaſon of which may be eaſily conceived.

DECAN, a province of the Hither India, bounded by the province of Cambaya, or Guzurat, on the north; by Golconda and Berar, on the eaſt; by Viſapour, on the ſouth; and by the Indian ocean on the weſt.

DECANDRIA, in the Linnæan ſyſtem of botany. See BOTANY, the *Scheme*, p. 635. and Plate LIII. fig. 10.

DECANTATION, among chemiſts, *&c.* the gently pouring off a liquor from its fæces, by inclining the lip or canthus of the veſſel; whence the name.

DECANUS, in Roman antiquity, an officer who preſided over other ten officers, and was head of the contuberinum, or ſerjeant of a file of ſoldiers.

DECAPROTI, *decemprimi*, in Roman antiquity, officers for gathering the tributes and taxes.

The decaproti were alſo obliged to pay for the dead, or to anſwer to the emperor for the quota parts of ſuch as died, out of their own eſtates.

DECASTYLE, in the ancient architecture, a building with an ordnance of ten columns in front, as the temple of Jupiter Olympius was.

DECEIT, in law, a ſubtle trick, or device, to which may be added all manner of craft and collufion, or underhand practice, uſed to defraud another, by any means whatever.

DECEMBER, the laſt month of the year, conſiſting of thirty-one days, and ſo called as being the tenth month in the Roman year, which commenced with March.

DECEMPEDA, in antiquity, a rule or rod divided into ten feet, each of which was ſubdivided into inches, and thoſe into digits, uſed in meaſuring of land, and, by architects, in giving the proper dimenſions and proportions to the parts of their buildings.

DECEMVIRI, in Roman antiquity, ten magiſtrates choſen annually at Rome, to govern the commonwealth inſtead of conſuls, with an abſolute power to draw up and make laws for the people.

One of the decemviri had all the enſigns and honours of the function, and the reſt had the like in their turn, during the year of their decemvirate. In them was veſted all the legiſlative authority ever enjoyed by the kings, or, after them, by the conſuls. It was the decemviri drew up the laws of the Twelve Tables, thence called *leges decemvirales*, which were the whole of the Roman law, for a conſiderable time.

DECENNALIA, ancient Roman feſtivals celebrated by the emperors, every tenth year of their reign, with ſacrifices, games, and largeſſes for the people. The emperor Auguſtus firſt inſtituted theſe ſolemnities, in which he was imitated by his ſucceſſors.

DECIDUOUS, an appellation chiefly uſed in reſpect of plants: thus, the calix or cup of a flower is ſaid to be deciduous, when it falls along with the flower-petals; and, on the contrary, it is called permanent, when it remains after they are fallen. Again, deciduous leaves are thoſe which fall in autumn, in contradiſtinction to thoſe of the ever-greens, which remain all the winter.

DECIL, in aſtronomy, an aſpect or poſition of two planets, when they are diſtant from each other a tenth part of the zodiac.

DECIMAL ARITHMETIC, the art of computing by decimal fractions.

DECIMAL FRACTION, in arithmetic. See Vol. I. p. 395.

DECIMATION, a puniſhment inflicted by the Romans, on ſuch ſoldiers as quitted their poſt, or behaved themſelves cowardly in the field. The names of all the guilty were put into an urn or helmet, and as many were drawn out as made the tenth part of the whole number, and theſe were put to the ſword, and the others ſaved.

DECIPHERING, the art of finding the alphabet of a cypher. See CYPHER.

Every language has, beſides the form of its characters, ſomething peculiar in the place, order, combination, frequency, and number of the letters; to all which particular regard is to be had in deciphering. In all languages, however, the following rules ought to be obſerved: 1. One word is to be compared with another, that their reſemblance and difference may be known. 2. No word can be without a vowel. 3. A word of one letter is always a vowel, or a conſonant with an apoſtrophe. 4. The vowels recur much more frequently than the conſonants. 5. Double vowels may be at the beginning of a word, but not double conſonants. 6. Double characters at the beginning of a word are always vowels. 7. Short words of two or three letters have two or three, or one or two conſonants. 8. The vowels are therefore moſt eaſily learned from the ſhort words which are to be firſt conſidered by the decipherer. 9. If double characters are preceded by a ſingle letter, the letter is a vowel. 10. In languages abounding with diphthongs one

one vowel is often joined with another. 11. The letter that precedes or follows double consonants is, if a consonant, always one of the liquids, *l*, *m*, *n*, *r*, 12. If two different characters occur, of which the latter is often conjoined with various letters, and the former is never found either by itself, or followed by any other letter, those two are *qu*. 13. These letters *qu* are always followed by a vowel. 14. One vowel recurs more frequently than another, as do the consonants, according to the language, *&c.*

DECISE, a town of the Orleanois, in France, situated on the river Loire, about fifteen miles south-east of Nevers: E. lon. 3° 32′, and N. lat. 46° 40′

DECK *of a ship* is a planked floor from stem to stern, upon which the guns lie, and where the men walk to and fro.

Great ships have three decks, first, second, and third, beginning to count from the lowermost.

Half deck reaches from the main-mast to the stem of the ship.

Quarter-deck is that aloft the steerage, reaching to the round house.

Flush-deck is that which lies even in a right-line fore and aft, from stem to stern. A rope-deck is that made of cordages, interwoven and stretched over a vessel, through which it is easy to annoy an enemy who comes to board her. They are little used but by small vessels, to defend them against privateers.

DECKENDORF, a town of Bavaria, in Germany, situated on the Danube, about thirty-seven miles south-east of Ratisbon: E. long. 13°, and N. lat. 48° 45′.

DECLAMATION, a speech made in public, in the tone and manner of an oration, uniting the expression of action to the propriety of pronunciation, in order to give the sentiment its full impression upon the mind.

DECLARATORY *action*, in Scots law, is that by which a pursuer only craves, that some right or privilege shall be declared to belong to him, without demanding the payment or performance of any thing from the defender. See SCOTS LAW, title, 30.

DECLENSION, in grammar, an inflexion of nouns according to their divers cases, as nominative, genitive, dative, *&c.* It is a different thing in the modern languages, which have not properly any cases, from what it is in the ancient Greek and Latin. With respect to languages, when the nouns admit of changes, either in the beginning, the middle, or ending; declension is properly the expression of all those changes in a certain order, and by certain degrees called cases. With regard to languages, where the nouns do not admit of changes in the same number, declension is the expression of the different states a noun is in, and the different relations it has; which difference of relations is marked by particles, and called articles, as *a*, *the*, *of*, *to*, *from*, *by*, &c.

DECLINATION, in astronomy, the distance of any celestial object from the equinoctial, either northward or southward. It is either true or apparent, according as the real or apparent place of the object is considered. See ASTRONOMY.

DECLINATION *of a wall or plane for dials*. See DIALLING.

DECLINATOR, or DECLINATORY, an instrument contrived for taking the declinations, inclinations, and reclinations of planes.

DECLINATURE *of judges*, in Scots law, declining the jurisdiction of a judge, or refusing to acquiesce in his judgment from any legal obligation to the judge himself, the incompetency of his jurisdiction to the nature of the action, or upon the privilege of the objector or decliner. See SCOTS LAW, title 2.

DECLIVITY denotes the reverse of acclivity. See ACCLIVITY.

DECOCTION, in pharmacy, the boiling simples, or other drugs, in order to extract their virtues for some medicinal purpose. The general subjects of decoction are animals and vegetables, and sometimes minerals, as antimony and quicksilver. The liquors which serve to boil them, are water, wine, vinegar, milk, and whey.

DECOMPOSITION, in chemistry, the reduction of a body into its principles or component parts. See CHEMISTRY.

DECORATION, in architecture, is used for whatever adorns a building, either withoutside or within.

DECORUM, in architecture, is the suitableness of a building, and the several parts and ornaments thereof, to the station and occasion.

DECOUPLE′, in heraldry, the same as uncoupled: thus a chevron decouplé, is a chevron wanting so much of it towards the point, that the two ends stand at a distance from one another, being parted and uncoupled.

DECOURS, in heraldry. See DECREMENT.

DECOY, a place made for catching wild-fowl. Hence,

DECOY-DUCK is a duck that flies abroad, and lights into company with wild ones, which by her allurements she draws into the decoy.

DECREE, an order made by a superior power, for the regulation of an inferior.

DECREE, in the civil law, is a determination that the emperor pronounces upon hearing a particular cause between plaintiff and defendant.

DECREE, or DECREET, in Scots law, the decisive sentence or judgment of a court of law.

DECREET-ARBITRAL, in Scots law, the sentence or judgment of one to whom parties voluntarily submit the determination of any question betwixt them. See SCOTS LAW, title 32.

DECREMENT, in heraldry, signifies the wane of the moon from the full to the new. The moon in this state is called moon decrescent, or in decours; and when borne in coat-armour, faces to the left side of the escutcheon, as she does to the right side when in the increment. See CRESCENT.

DECREPITATION, in chemistry, the act of calcining salt over the fire, till it cease to crackle. See CHEMISTRY.

It is alſo applied to the crackling of the ſalts during the operation.

DECRETAL, in the canon-law, a letter of a pope, determining ſome point or queſtion in the eccleſiaſtical law. The decretals compoſe the ſecond part of canon law. The firſt genuine one acknowledged by all the learned as ſuch, is the letter of pope Siricius, written in the year 385, to Himerus biſhop of Tarragona in Spain, concerning ſome diſorders which had crept into the churches of Spain.

DECUMANI DENTES, in heraldry. See DANCETTE.

DECUPLE PROPORTION, that of ten to one.

DECURIO, in Roman antiquity, a commander of ten men in the army, or the chief of a decury.

DECURRENT LEAF. See BOTANY, p. 641.

DECURY, ten perſons ranged under one chief, or leader, called the decurio.

The Roman cavalry was divided into decuries, which were ſubdiviſions of a century, each century containing ten decuries.

DECUSSATION, a term in geometry, optics, and anatomy, ſignifying the croſſing of any two lines, rays, or nerves, when they meet in a point, and then go on ſeparately from one another.

DECUSSORIUM, a ſurgeon's inſtrument, which, by preſſing gently on the dura mater, cauſes an evacuation of the pus collected between the cranium and the before mentioned membrane, through the perforation made by the trepan.

DEDDINGTON, a market town of Oxfordſhire, about fifteen miles north of Oxford: W. long. 1° 20′, and N. lat. 51° 55′.

DEDHAM, a market-town in Eſſex, about thirty-five miles north-eaſt of Chelmsford: E. long. 1° 10′, and N. lat. 52° 5′.

DEDICATION, a ſolemn devoting or ſetting apart any perſon or thing to the ſervice of God and the purpoſes of religion.

Feaſt of DEDICATION, an anniverſary feſtival among the Jews, in memory of Judas Maccabæus, who repaired and dedicated anew the temple and altar, which had been plundered and profaned by Antiochus Epiphanes. It was obſerved on the twenty-fifth of Ciſleu, and continued eight days.

DEE, the name of ſeveral rivers, as that on which Cheſter ſtands, that whereon Aberdeen ſtands, *&c.*

DEED, in Scots laws, any ſettlement, diſpoſition, contract, or other legal writing.

DEED, an inſtrument written on paper or parchment, comprehending ſome contract, bargain or agreement between the parties thereto, in relation to the matter therein contained.

DEEMSTERS, or DEMSTERS. All controverſies in the Iſle of Man are decided without proceſs, writings, or any charges, by certain judges, choſen yearly from among themſelves, called deemſters; there being two of them for each diviſion of the iſland: they ſit judges in all courts, either for life or property; and with the advice of twenty-four keys, declare what is law, in uncommon emergencies.

DEEPING, a market-town of Lincolnſhire, about thirty-five miles ſouth of Lincoln: W. long. 20°, and N. lat. 52° 35′.

DEER, in zoology. See CERVUS.

DEFAMATION, the ſpeaking ſlanderous words of another; for which the ſlanderer is puniſhable, according to the nature of his offence, either by action upon the caſe at common law, or by ſtatute, or in the eccleſiaſtical court.

DEFAULT, in law, is generally taken for non-appearance in court, at a day aſſigned; but imports any omiſſion of that which we ought to do, for which judgment may be given againſt the defaulter.

DEFEASANCE. See DEFEISANCE.

DEFECATE, or DEFÆCATE, in chemiſtry, a term applied to a body freed and purged from fæces and impurities,

DEFEISANCE, in law, a condition relating to ſome certain deed, which being performed, the deed is defeated and rendered void, as if it had never been made.

DEFENCE, in fortification, all ſorts of works that cover and defend the oppoſite poſts, as flanks, caſements, parapets, and fauſſebrays. See FORTIFICATION.

Line of DEFENCE, a ſuppoſed line drawn from the angle of the curtin, or from any other part in the curtin, to the flanked angle of the oppoſite baſtion. See FORTIFICATION.

DEFENDER *of the faith*, a peculiar title, belonging to the king of Great Britain, as Catholic does to the king of Spain, Chriſtian to the king of France, *&c.*

This title was firſt given by pope Leo X. to king Henry VIII. for writing againſt Luther.

DEFERENT, in anatomy, a term applied to certain veſſels in the body, that ſerve for the conveyance of humours from one part to another. See ANATOMY.

DEFERENT, in the Ptolemaic aſtronomy, a circle invented to account for the eccentricity, perigee, and apogee of the planets.

DEFERENTIA VASA. See Vol. I. p. 273.

DEFILE, in fortification, a ſtrait narrow paſſage, thro' which a company of horſe or foot can paſs only in file, by making a ſmall front.

DEFINITE, in grammar, is applied to an article that has a preciſe determinate ſignification; ſuch as the article *the* in Engliſh, *le* and *la* in French, *&c.* which fix and aſcertain the noun they belong to, to ſome particular, as *the king*, *le roy*; whereas in the quality *of king*, *de roy*, the articles *of* and *de* mark nothing preciſe, and are therefore indefinite.

DEFINITION, an idea of any ſcience, ſubject, *&c.* conveyed in a few words.

DEFINITIVE, a term applied to whatever terminates a proceſs, queſtion, *&c.* in oppoſition to proviſional and interlocutory.

DEFLAGRATION, in chemiſtry, the kindling or ſetting fire to a ſalt or mineral, *&c.* either alone, or mixed for that purpoſe with a ſulphureous one in order to purify it. See CHEMISTRY.

DEFLECTION *of the rays of light*. See OPTICS.

DEFLUXION, in medicine, the falling of humours from a ſuperior to an inferior part of the body.

DEFORCEMENT,

DEFORCEMENT, in Scots law, the oppoſing or reſiſting the officers of the law in the execution of their office. See Scots Law, titles 25 and 33.

DEFORMITY, the want of that uniformity neceſſary to conſtitute the beauty of an object. See Beauty.

DEGENERATION, or Degenerating, in general, denotes the growing worſe, or loſing ſome valuable qualities whereof a thing was formerly poſſeſſed.

DEGLUTITION, in medicine, the act of ſwallowing the food, performed by means of the tongue driving the aliment into the œſophagus, which, by the contraction of the ſphincter, protrudes the contents downwards.

DEGRADATION, the act of depriving a perſon for ever of a dignity or degree of honour, and taking away the title, badge, and privileges of it.

Degradation, in painting, expreſſes the leſſening the appearance of diſtant objects in a landſkip, in the ſame manner as they would appear to an eye placed at that diſtance from them.

DEGRADED CROSS, in heraldry, a croſs divided into ſteps at each end, diminiſhing as they aſcend towards the centre, called by the French *perronnée*. See Plate LXVIII. fig. 6.

DEGREE, in geometry, a diviſion of a circle, including a three hundred and ſixtieth part of its circumference. See Astronomy, and Geography.

Degree *of latitude*. See Geography.

Degree *of longitude*. See Geography.

Degrees, in muſic, are the little intervals whereof the concords or harmonical intervals are compoſed.

Degree, in univerſities, denotes a quality conferred on the ſtudents or members thereof as a teſtimony of their proficiency in the arts or ſciences, and intitling them to certain privileges.

DEJECTION, in medicine, the act of ejecting or evacuating the excrements. It is alſo applied to the excrements themſelves thus evacuated, in which ſenſe it is of the ſame import with ſtool.

DEIFICATION, in antiquity. See Apotheosis.

DEISM, the ſyſtem of religion acknowledged by the deiſts.

DEISTS, in the modern ſenſe of the word, are thoſe perſons in Chriſtian countries, who, acknowledging all the obligations and duties of natural religion, diſbelieve the Chriſtian ſcheme, or revealed religion. They are ſo called from their belief in God alone, in oppoſition to Chriſtians. The learned Dr Clarke taking the denomination in the moſt extenſive ſignification, diſtinguiſhes deiſts into four ſorts. 1. Such as pretend to believe the exiſtence of an eternal, infinite, independent, intelligent Being; and who teach, that this ſupreme Being made the world, though they fancy he does not at all concern himſelf in the management of it. 2. Thoſe who believe not only the being, but alſo the providence of God with reſpect to the natural world; but who, not allowing any difference between moral good and evil, deny that God takes any notice of the morally good or evil actions of men; theſe things depending, as they imagine, on the arbitrary conſtitutions of human laws. 3. Thoſe who having right apprehenſions concerning the natural attributes of God, and his all governing providence, and ſome notion of his moral perfections alſo; yet, being prejudiced againſt the notion of the immortality of the human ſoul, believe that men periſh entirely at death, and that one generation ſhall perpetually ſucceed another, without any future reſtoration or renovation of things. 4. Such as believe the exiſtence of a ſupreme Being, together with his providence in the government of the world, as alſo the obligations of natural religion; but ſo far only as theſe things are diſcoverable by the light of nature alone, without believing any divine revelation. Theſe laſt are the only true deiſts; but as the principles of theſe men would naturally lead them to embrace the Chriſtian revelation, the learned author concludes there is now no conſiſtent ſcheme of deiſm in the world.

DEITY, a term frequently uſed in a ſynonymous ſenſe with God.

DELEGATES, commiſſioners appointed by the king under the great ſeal to hear and determine appeals from the eccleſiaſtical court.

DELEGATION, a commiſſion extraordinary given by a judge to take cognizance of and determine ſome cauſe which ordinarily does not come before him.

DELEGATION, in Scots law, a method of extinguiſhing obligations by the creditor's diſcharging his former debitor upon another becoming bound in his place.

DELETERIOUS, an appellation given to things of a deſtructive or poiſonous nature. See Poison.

DELF, in heraldry, is by ſome ſuppoſed to repreſent a ſquare rod or turf, and to be ſo called from delving, or digging. A delf tenne is due to him that revokes his own challenge, or any way goes from his word; and to ſuch this is given as an abatement to the honour of their arms, and is always placed in the middle of the eſcutcheon. However, if two or more delfs are found in an eſcutcheon, they are not then to be looked upon as ſigns of an abatement, but of honour. Alſo, if it be of metal, or charged upon, it then becomes a charge of perfect bearing.

DELFT, a city of the United Netherlands, in the province of Holland, eight miles north-eaſt of Rotterdam, and thirty ſouth-weſt of Amſterdam: E. long. 4° 5′, and N. lat. 52° 6′.

DELIA, in antiquity, feaſts celebrated by the Athenians in honour of Apollo, ſurnamed Delius.

Delia was alſo a quinquennial feſtival in the iſland of Delos, inſtituted by Theſeus at his return from Crete, in honour of Venus, whoſe ſtatue, given him by Ariadne, he erected on that place, having by her aſſiſtance met with ſucceſs in his expedition.

DELIBAMENTA, in antiquity, a libation to the infernal gods, always offered by pouring downwards. See Libation.

Jus DELIBERANDI, in Scots law, an apparent heir is allowed a year after his predeceſſor's death, called *annus deliberandi*, to deliberate whether he will enter and repreſent him or not, during which time he cannot be purſued for the debts of his predeceſſor. See Scots Law, title 27.

DELIBERATIVE,

DELIBERATIVE, an appellation given to a kind or branch of rhetoric, employed in proving a thing, or convincing an aſſembly thereof, in order to perſuade them to put it in execution.

To have a deliberative voice in the aſſembly, is when a perſon has a right to give his advice and his vote therein. In councils, the biſhops have deliberative voices; thoſe beneath them have only conſultative voices.

DELICT, in Scots law, ſignifies ſuch ſmall offences or breaches of the peace as are puniſhable only by fine or ſhort impriſonment. See SCOTS LAW, title 33.

DELIMA, in botany, a genus of the polyandria monogynia claſs. It has no corolla; the calix conſiſts of five leaves; and the berry contains two ſeeds. There is but one ſpecies, a native of Ceylon.

DELINEATION. See DESIGNING.

DELINQUENT, a guilty perſon, or one who has committed ſome fault or offence, for which he is puniſhable.

DELIQUIUM, or ANIMI DELIQUIUM. See LIPOTHYMIA.

DELIQUIUM, in chemiſtry, ſignifies the ſolution of any body, when expoſed to a cool and damp place, by the humidity it attracts from the air.

DELIRIUM, in medicine, the production of ideas not anſwerable to external cauſes, from an internal indiſpoſition of the brain. See MEDICINE.

DELIVERY, or CHILD-BIRTH. See MIDWIFERY.

DELLY, the capital of a province of the ſame name, and at preſent of all the Hither India: E. long. 79°, and N. lat. 28.

DELOS, the principal of the Cyclades-iſlands, in the Archipelago: E. long. 25° 50′, and N. lat. 37° 26′.

DELPHINIUM, or LARK'S SPUR, in botany, a genus of the polyandria trigynia claſs. It has no calix; the corolla conſiſts of five petals; and the nectarium is bifid, and horned behind. There are ſeven ſpecies, only one of which, *viz.* the conſolida, or wild lark's-ſpur, is a native of Britain.

DELPHINUS, or DOLPHIN, in ichthyology, a genus belonging to the order of cete; the characters of which are theſe: they have teeth in each jaw; and a fiſtula or pipe in the head. There are three ſpecies, *viz.* 1. The phocœna, with a conical body, a broad back, and an obtuſe ſnout. The colour of the back is a blackiſh blue, and the belly is white. The fiſtula, or pipe, through which they breathe and ſpout up the water, is betwixt the eyes: it has forty-ſix teeth in each jaw: it is found in the Baltic and different parts of the European ocean. The ſkin is ſmooth and ſoft. The external orifice of the fiſtula reſembles the letter C: it has two ſtrong pectoral fins, and a cartilaginous fin on the back. The tail is bifid. The penis of the male is not covered with a præputium, it lies concealed within the body, but is eaſily protruded when occaſion requires. In the female, the cervix of the vulva is about nine inches long, and ſituate betwixt the navel and anus. They copulate in the ſummer; bring forth one at a birth; they nouriſh their young with milk; and they live about thirty years. They live ſeveral days out of the water, provided they be not wounded. See Plate LXVIII. fig. 2. It is about four feet long, and two and a half thick. 2. The delphus, or dolphin of the ancients, is of an oblong cylindrical ſhape, and the ſnout is ſharp and tapering; the teeth are ſubulated. It likewiſe frequents the European ocean. 3. The orca, or leſſer whale of Ray, has the upper part of the ſnout waved, and broad ſerrated teeth. The inferior jaw is much longer than the ſuperior one.

DELPHINUS, in aſtronomy, a conſtellation of the northern hemiſphere. See ASTRONOMY.

DELSBERG, or DESBERG, a town of Switzerland, about ſeventeen miles ſouth-weſt of Baſil.

DELTOIDES, in anatomy. See Vol. I. p. 195.

DELUGE, an inundation or overflowing of the earth, either wholly or in part, by water.

We have ſeveral deluges recorded in hiſtory, as that of Ogyges, which overflowed almoſt all Attica; and that of Deucalion, which drowned all Theſſaly in Greece: but the moſt memorable was that called the univerſal deluge, or Noah's flood, which overflowed and deſtroyed the whole earth, and out of which only Noah, and thoſe with him in the ark, eſcaped. See ARK.

Many attempts have been made to account for the deluge by means of natural cauſes: but theſe attempts have only tended to diſcredit philoſophy, and to render their authors ridiculous.

DEMAIN, or DEMESNE, in its common acceptation, is uſed for the lands round a manor-houſe, occupied by the lord.

DEMAIN, or DEMESNE, in law, is commonly underſtood to be the lord's chief manor-place, with the lands thereto belonging, which he and his anceſtors have time out of mind kept in their own manual occupation.

DEMEMBRE', in heraldry, is ſaid of diſmembered animals, or thoſe with their limbs cut off.

DEMEMBRATION, in Scots law, ſignifies either the crime of depriving another of any member of his body, or the puniſhment of a crime by cutting off any member of the criminal's body. See SCOTS LAW, title 33.

DEMER, a river in the Auſtrian Netherlands, on which the city of Mechlin ſtands.

DEMESNE. See DEMAIN.

DEMETRIA, a feſtival celebrated by the Greeks in honour of Ceres, wherein it was uſual for the devotees to laſh themſelves.

DEMETRIOWITZ, a city of the dutchy of Smolenſko, in the Ruſſian empire, ſituated upon the river Ugra, in 37° E. long. and 52° 30′ N. lat.

DEMI, a word uſed in compoſition with other words to ſignify half.

DEMI-CULVERIN, a piece of ordnance uſually $4\frac{1}{2}$ inches bore, 2700 pound weight, ten feet long, and carrying point blank 175 paces.

DEMI-CULVERIN *of the leaſt ſize*, is $4\frac{1}{4}$ inches bore,

Fig. 4. DIODON
A. Bell Sct

10 feet long, and 2000 pounds weight. It carries a ball of 4 inches diameter, and of 9 pounds weight, and its level range is 174 paces.

DEMI-CULVERIN *of the largeſt ſort*, is $4\frac{3}{4}$ inches bore, $10\frac{1}{2}$ feet long, and weighs 3000 pounds weight. It carries a ball $4\frac{1}{2}$ inches diameter, weighing 12 pounds 11 ounces, point blank 178 paces.

DEMI-GORGE, in fortification, is that part of the polygon which remains after the flank is raiſed, and goes from the curtin to the angle of the polygon. It is half of the vacant ſpace or entrance into a baſtion.

DEMI-QUAVER, a note in muſic, two of which are equal to a quaver.

DEMI-SEMI-QUAVER, in muſic, the ſhorteſt note, two of them being equal to a ſemi-quaver.

DEMOCRACY, the ſame with a popular government, wherein the ſupreme power is lodged in the hands of the people: ſuch were Rome and Athens of old; but as to our modern republics, Baſil only excepted, their government comes nearer to ariſtocracy than democracy.

DEMONSTRABLE, a term uſed in the ſchools, to ſignify that a thing may be clearly proved. Thus it is demonſtrable that the three angles of a triangle are equal to two right ones.

DEMONSTRATION, in logic, a ſeries of ſyllogiſms, all whoſe premiſes are either definitions, ſelf-evident truths, or propoſitions already eſtabliſhed. See LOGIC.

DEMONSTRATIVE, in grammar, a term given to ſuch pronouns as ſerve to indicate or point out a thing. Of this number are *hic*, *hæc*, *hoc*, among the Latins; and *this*, *that*, *theſe*, *thoſe*, in Engliſh.

DEMULCENTS, among phyſicians, medicines good againſt acrimonious humours. Such are the roots of marſh-mallows, of white lilies, of liquorice, and of viper graſs, the five emollient herbs, *&c.*

DEMURRAGE, in commerce, an allowance made to the maſter of a ſhip by the merchants, for ſtaying in a port longer than the time firſt appointed for his departure.

DEMURRER, in law, a ſtop put to any action upon ſome point of difficulty which muſt be determined by the court, before any further proceedings can be had in the ſuit.

DEN, a ſyllable which added to the names of places ſhews them to be ſituated in valleys or near woods, as Tenterden.

DENARIUS, in Roman antiquity, the chief ſilver coin among the Romans, worth in our money about ſevenpence three farthings. As a weight, it was the ſeventh part of a Roman ounce.

DENARIUS is alſo uſed in our law books for an Engliſh penny.

DENBY, the capital of Denbyſhire, in North Wales: W. long. 3° 30′, and N. lat. 53° 15′. It ſends only one member to parliament.

DENDERMOND, a fortified town of Flanders, ſituated at the confluence of the rivers Scheld and Dender, twelve miles eaſt of Ghent: E. long. 3° 50′, and N. lat. 51° 10′.

DENDRACHATES, in natural hiſtory, the name uſed by the ancients for an extremely elegant and beautiful ſpecies of agate, the ground of which is whitiſh, variegated with veins of a brighter white. Theſe veins are beautifully diſpoſed in a number of various figures, but generally in many concentric irregular circles, drawn round one or more points. It is common alſo, in various parts of this ſtone, to find very beautiful delineations of trees, moſſes, ſea-plants, and the like, ſo elegantly expreſſed, that many have erroneouſly taken them for real plants included in the ſubſtance of the ſtone; whence the name dendrachates.

DENDRANATOMY, a term uſed by ſome for a deſcription of the various parts of trees, as root, trunk, branch, bark, wood, pith, flower, fruit, *&c.* See AGRICULTURE, Part I.

DENDROPHORIA, in antiquity, the carrying of boughs or branches of trees, a religious ceremony ſo called, becauſe certain prieſts called from thence dendrophori, tree-bearers, marched in proceſſion, carrying the branches of trees in their hands in honour of ſome god, as Bacchus, Cebele, Sylvanus, *&c.* The college of the dendrophori is often mentioned in ancient marbles; and we frequently ſee in baſſo relievos the bacchanals repreſented as men carrying little ſhrubs or branches of trees.

DENEB, an Arabic term ſignifying tail, uſed by aſtronomers to denote ſeveral fixed ſtars. Thus deneb eleet, ſignifies the bright ſtar in the lion's tail. Deneb adigege, that in the ſwan's tail, *&c.*

DENIER, a ſmall French copper-coin, of which twelve make a ſol.

There were two kinds of deniers, the one tournois, the other pariſis, whereof the latter was worth a fourth part more than the former.

DENIZEN, in law, an alien made a ſubject by the king's letters patent, otherwiſe called donaiſon, becauſe his legitimation proceeds *ex donatione regis*, from the king's gift.

DENMARK, a kingdom ſituated between 8° and 13° of E. long. and between 54° and 58° of N. lat.: it comprehends the peninſula of Jutland, and the iſlands of Zeland, Funen, *&c.* To the king of Denmark likewiſe belong Norway, Iceland, and the dutchy of Holſtein.

DENNIS, or ST DENNIS, a town of France four miles north of Paris, where the kings of France are interred.

DENOMINATOR, in arithmetic, a term uſed in ſpeaking of fractions. See ARITHMETICK, p. 387.

DENS CANIS, or DOG'S-TOOTH, in botany. See ERYTHRONIUM.

DENS LEONIS. See LEONTODON.

DENSITY *of bodies*, is that property directly oppoſite to rarity, whereby they contain ſuch a quantity of matter under ſuch a bulk.

Accordingly, a body is ſaid to have double or triple the denſity of another body, when their bulk being equal, the quantity of matter is in the one double or triple the quantity of matter in the other.

DENSITY *of the air*. See PNEUMATICS.

DENTALIUM, in natural hiſtory, a ſhell-fiſh belonging to the order of vermes teſtacea. The ſhell conſiſts of one tubulous ſtrait valve, open at both ends. There are eight ſpecies, diſtinguiſhed by the angles, ſtriæ, *&c.* of their ſhells.

DENTARIA, or TOOTHWORT, in botany, a genus of the tetradynamia ſiliquoſa claſs. The ſiliqua or pod burſts open by elaſtic valves; the ſtigma is emarginated; and the calix is connivent. There are three ſpecies, only one of which, *viz.* the bulbifera, or coralwort, is a native of Britain.

DENTATED LEAF. See botany, p. 640.

DENTEX, in ichthyology. See SPARUS.

DENTILES, or DENTILS, in architecture, an ornament in corniches bearing ſome reſemblance to teeth, particularly uſed in the Ionic and Corinthian orders. See ARCHITECTURE, p. 352.

DENTIFRICE, in medicine, a remedy for rubbing the teeth, and purging them from ſordes; and for cleanſing and abſterging the gums, when replete with humours. There are dentifrices of various kinds and forms; ſome in form of a powder compoſed of corals, pumice-ſtone, ſalt, allum, egg-ſhells, crabs-claws, hartſhorn, *&c.* others in form of an electuary, conſiſting of the ſame powders mixt up with honey; others are in form of a liquor drawn by diſtillations from drying herbs, and aſtringent medicines, *&c.*

DENTILLARIA. See PLUMBAGO.

DENTISCALPRA, in ſurgery, an inſtrument for ſcouring yellow, livid, or black teeth; to which being applied, near the gums, it ſcrapes off the foul morbid cruſt.

DENTITION, the breeding or cutting the teeth in children. See MEDICINE.

DENUNCIATION, a ſolemn publication or promulgation of any thing.

All veſſels of enemies are lawful prizes, after denunciation or proclamation of war. The deſign of the denunciation of excommunicated perſons, is that the ſentence may be the more fully executed by the perſon's being more known.

DENUNCIATION at the horn, in Scots law, is that form by which a debtor, after the expiry of a charge to make payment upon letters of horning, is denounced rebel to the king for diſobedience. No caption for apprehending and impriſoning the debtor can be obtained upon an expired charge of horning till he is firſt denounced rebel, and the horning with the executions of charge and denunciation regiſtered. As to the other legal effects of denunciation, ſee SCOTS LAW, title 12.

DEOBSTRUENTS, in pharmacy, ſuch medicines as open obſtructions. See DETERGENT.

DEODAND, in our cuſtoms, implies a thing devoted or conſecrated to God, for the pacification of his wrath, in caſe of any misfortune; as a perſon's coming to a violent end, without the fault of any reaſonable creature; as if a horſe ſhould ſtrike his keeper, and ſo kill him. In this caſe, the horſe is to be a deodand; that is, he is to be ſold, and the price diſtributed to the poor, as an expiation of that dreadful event.

DEPONENT, in Latin grammar, a term applied to verbs which have active ſignifications, but paſſive terminations or conjugations, and want one of their participles paſſive.

DEPONENT, in the law of Scotland, a perſon who makes a depoſition. See DEPOSITION.

DEPOPULATION, the act of diminiſhing the number of people in any country, whether by war or bad politics.

DEPORTATION, a ſort of baniſhment uſed by the Romans, whereby ſome iſland or other place was allotted to a criminal for the place of his abode, with a prohibition not to ſtir out of the ſame on pain of death.

DEPOSIT, among civilians, ſomething that is committed to the cuſtody of a perſon, to be kept without any reward, and to be returned again on demand.

DEPOSITARY, in law, a perſon intruſted as keeper or guardian of a depoſit.

DEPOSITATION, in Scots law, is a contract by which one commits the cuſtody or poſſeſſion of any thing to another, to be kept for behoof of the owner, and returned on demand, or at any period ſpecified in the contract. The owner is called the depoſitor, and the perſon to whoſe cuſtody the thing is committed the depoſitary. See SCOTS LAW, title 20.

DEPOSITION, in law, the teſtimony given in court by a witneſs upon oath.

DEPRECATION, in rhetoric, a figure whereby the orator invokes the aid and aſſiſtance of ſome one; or prays for ſome great evil or puniſhment to befal him who ſpeaks falſely, either himſelf or his adverſary.

DEPRECATORY, or DEPRECATIVE, in theology, a term applied to the manner of performing ſome ceremonies in the form of prayer.

The form of abſolution is deprecative in the Greek church, being conceived in theſe terms, *May God abſolve you:* whereas it is in the declarative form in the Latin church, and in ſome of the reformed churches, *I abſolve you.*

DEPRESSION *of the pole.* See ASTRONOMY, and GEOGRAPHY.

DEPRESSOR, or DEPRIMENS, in anatomy, a name applied to ſeveral muſcles, becauſe they depreſs the parts they are faſtened to.

DEPRIVATION, in the canon-law, the depoſing a biſhop, parſon, vicar, *&c.* from his office and preferment.

DEPTFORD, a town three miles eaſt of London, on the ſouthern banks of the Thames; chiefly conſiderable for its fine docks for building ſhips, and the king's yard.

DEPURATION. See CLARIFICATION.

DEPURATORY FEVER, a name given by Sydenham to a fever which prevailed much in the years 1661, 1662, 1663, and 1664. He called it depuratory, becauſe he obſerved, that nature regulated all the ſymptoms in ſuch a manner, as to fit the febrile matter, prepared by proper concoction, for expulſion in a certain time, either by a copious ſweat, or a freer perſpiration.

DEPUTATION, a miſſion of ſelect perſons out of a company

company or body, to a prince or aſſembly, to treat of matters in their name.

DEPUTY, a perſon ſent upon ſome buſineſs, by ſome community.

DEPUTY is alſo one that exerciſes an office in another's right; and the forfeiture or miſdemeanor of ſuch deputy ſhall cauſe the perſon whom he repreſents to loſe his office.

DEPUTATUS, among the ancients, a name applied to perſons employed in making of armour: and likewiſe to briſk active people, whoſe buſineſs was to take care of the wounded in engagements, and carry them off the field.

DERBENT, a city of Dagiſtan, on the weſtern coaſt of the Caſpian ſea: E. long. 51°, and 41° 15′ N. lat.

DEREHAM, a market-town of Norfolk, about fifteen miles weſt of Norwich: E. long. 1°, and N. lat. 52° 40′.

DERIVATIVE, in grammar, a word which is derived from another called its primitive. See PRIMITIVE.

Thus, *manhood* is derived from *man*, *deity* from *Deus*, and *lawyer* from *law*.

DERMESTES, in zoology, a genus of inſects belonging to the order of coleoptera. The antennæ are clavated, with three of the joints thicker than the reſt; the breaſt is convex; and the head is inflected below the breaſt. There are thirty ſpecies, diſtinguiſhed by their colour, *&c.*

DERNIER RESSORT. See RESSORT.

DEROGATORY, a clauſe importing derogation. A derogatory clauſe in a teſtament, is a certain ſentence, cipher, or ſecret character, which the teſtator inſerts in his will, and of which he reſerves the knowledge to himſelf alone, adding a condition, that no will he may make hereafter is to be reckoned valid, if this derogatory clauſe is not inſerted expreſsly, and word for word. It is a precaution invented by lawyers againſt latter-wills extorted by violence, or obtained by ſuggeſtion.

DERPT, a town of Livonia, ſituated on the tiver Eimbec: E. long. 28° 10′, and N. lat. 58° 10′.

DERVIS, a name given to all Mahommedan monks, though of various orders. The moſt noted among them are the Bektaſhi, the Mevelevi, the Kadri, and the Seyah. The Bektaſhi, who are allowed to marry and live in cities and towns, are obliged, by the rules of their order, to viſit remote lands, and to ſalute every one they meet with *gazel*, or love-ſongs, and with *eſma*, or the invocation of the names of God, and humbly to wiſh him proſperity, which they do by repeating the word *eivallah*, a ſolemn exclamation of the wreſtlers, by which the conquered yields the palm to the conqueror. The Mevelevi, ſo called from Mevelava their founder, are uſed to turn round for two or three hours together, with ſuch ſwiftneſs that you cannot ſee their faces; they are great lovers of muſic: in their monaſteries they profeſs great humility and poverty, and when viſited make no diſtinction of perſons; they firſt bring their gueſts coffee to drink; and if the ways have been dirty, they waſh their feet and ſandals. The Kadri, with a peculiar ſuperſtition, emaciate their bodies; they go quite naked, except their thighs, and often join hands and dance, ſometimes a whole day, repeating with great vehemence, *hu! hu! hu!* (one of the names of God) till, like madmen, they fall on the ground, foaming at the mouth, and running down with ſweat: the prime vizir Kupruli Achmed Paſha, thinking this ſect unbecoming the Mahommedan religion, ordered it to be ſuppreſſed; but, after his death, it revived, and is at preſent more numerous than ever, eſpecially at Conſtantinople. The Seyah are wanderers, and though they have monaſteries, yet they often ſpend their whole life in travelling; when they are ſent out, their ſuperiors impoſe upon them ſuch a quantity of money or proviſions, forbidding them to come back till they have procured it, and ſent it to the monaſtery; wherefore when a Seyah comes into a town, he cries aloud in the market-place, *Ya allah ſenden*, &c. *O God! give me, I pray, five thouſand crowns*, or *a thouſand meaſures of rice.* Many of theſe derviſes travel over the whole Mahommedan world, entertaining the people where-ever they come, with agreeable relations of all the curioſities they have met with. There are derviſes in Egypt, who live with their families, and exerciſe their trades, of which kind are the dancing derviſes at Damaſcus. They are all diſtinguiſhed among themſelves by the different forms and colours of their habits; thoſe of Perſia wear blue; the ſolitaries and wanderers wear only rags of different colours; others carry on their heads a plume made of the feathers of a cock; and thoſe of Egypt wear an octagonal badge of a greeniſh white alabaſter at their girdles, and a high ſtiff cap, without any thing round it.

DERWENT, a river, which, taking its riſe in the north riding of Yorkſhire, runs ſouth, and falls into the Ouſe.

DERWENT-WATER, a river of Cumberland, which falls into the Iriſh ſea below Cockermouth.

DESART, a large extent of country entirely barren, and producing nothing. In this ſenſe ſome are ſandy deſarts, as thoſe of Lop, Xamo, Arabia, and ſeveral others in Aſia; in Africa, thoſe of Lybia and Zara: others are ſtony, as the deſart of Pharan in Arabia Petrea.

The DESART, abſolutely ſo called, is that part of Arabia, ſouth of the Holy Land, where the children of Iſrael wandered forty years.

DESCANT, in muſic, the art of compoſing in ſeveral parts. See MUSIC.

DESCENDENTS, in Scots law. The iſſue of a common parent *in infinitum* are called his deſcendents.

DESCENSION, in aſtronomy, is either right or oblique.

Right DESCENSION is an arch of the equinoctial, intercepted between the next equinoctial point and the interſection of the meridian, paſſing through the centre of the object, at its ſetting, in a right ſphere.

Oblique DESCENSION, an arch of the equinoctial, intercepted

tercepted between the next equinoctial point and the horizon, paſſing through the centre of the object, at its ſetting, in an oblique ſphere.

DESCENT, in general, is the tendency of a body from a higher to a lower place; thus all bodies, unleſs otherwiſe determined by a force ſuperior to their gravity, deſcend towards the centre of the earth. See Mechanics.

Descent, or Discent, in law, an order or method whereby lands or tenements are derived to any man from his anceſtors.

Descent, in genealogy, the order or ſucceſſion of deſcendants in a line or family; or their diſtance from a common progenitor: thus we ſay, one deſcent, two deſcents, *&c.*

Descent, in heraldy, is uſed to expreſs the coming down of any thing from above; as, a lion en deſcent, is a lion with his head towards the baſe points, and his heels towards one of the corners of the chief, as if he were leaping down from ſome high place.

DESCRIPTION, is ſuch a ſtrong and beautiful repreſentation of a thing, as gives the reader a diſtinct view and ſatisfactory notion of it. See Narration *and Deſcription.*

DESEADA, or Desiderada, one of the Caribbee-iſlands, ſubject to France, lying eaſtward of Guardaloupe. See Caribbee.

DESERTER, in a military ſenſe, a ſoldier who, by running away from his regiment or company, abandons the ſervice.

A deſerter is, by the articles of war, puniſhable by death, and, after conviction, is hanged at the head of the regiment he formerly belonged to, with his crime writ on his breaſt.

DESERTION, in Scots Law, when one of the married perſons deſerts or forſakes the other. Wilful deſertion for four years together is a ground of divorce. See Scots Law, title 6.

DESHACHE', in heraldry, is where a beaſt has its limbs ſeparated from its body, ſo that they ſtill remain on the eſcutcheon, with only a ſmall ſeparation from their natural places.

DESIDERATUM is uſed to ſignify the deſirable perfections in any art or ſcience: thus, it is a deſideratum with the blackſmith, to render iron fuſible by a gentle heat, and yet preſerve it hard enough for ordinary uſes; with the glaſsman, and looking-glaſs maker, to render glaſs malleable; with the clock-maker, to bring pendulums to be uſeful where there are irregular motions, *&c.*

DESIGN, in a general ſenſe, the plan, order, repreſentation, or conſtruction of a building, book, painting, *&c.*

Design, in the manufactories, expreſſes the figures wherewith the workman enriches his ſtuff, or ſilk, and which he copies after ſome painter, or eminent draughts-man, as in diaper, damaſk, and other flowered ſilk and tapeſtry, and the like.

In undertaking of ſuch kinds of figured ſtuffs, it is neceſſary, ſays Monſ. Savary, that, before the firſt ſtroke of the ſhuttle, the whole deſign be repreſented on the threads of the warp; we do not mean in colours, but with an infinite number of little packthreads, which, being diſpoſed ſo as to raiſe the threads of the warp, let the workmen ſee, from time to time, what kind of ſilk is to be put in the eye of the ſhuttle for woof. This method of preparing the work is called reading the deſign, and reading the figure, which is performed in the following manner: a paper is provided, conſiderably broader than the ſtuff, and of a length proportionate to what is intended to be repreſented thereon. This they divide lengthwiſe, by as many black lines as there are intended threads in the warp; and croſs theſe lines, by others drawn breadthwiſe, which, with the former, make little equal ſquares: on the paper thus ſquared, the draughtsman deſigns his figures, and heightens them with colours, as he ſees fit. When the deſign is finiſhed, a workman reads it, while another lays it on the ſimblot.

To read the deſign, is to tell the perſon who manages the loom, the number of ſquares, or threads, compriſed in the ſpace he is reading, intimating at the ſame time, whether it is ground or figure. To put what is read on the ſimblot, is to faſten little ſtrings to the ſeveral packthreads, which are to raiſe the threads named; and thus they continue to do till the whole deſign is read.

Every piece being compoſed of ſeveral repetitions of the ſame deſign, when the whole deſign is drawn, the drawer, to re-begin the deſign afreſh, has nothing to do but to raiſe the little ſtrings, with ſlip-knots, to the top of the ſimblot, which he had let down to the bottom: this he is to repeat as often as is neceſſary till the whole be manufactured.

The ribbon-weavers have likewiſe a deſign, but far more ſimple than that now deſcribed. It is drawn on paper with lines and ſquares, repreſenting the threads of the warp and woof. But inſtead of lines, whereof the figures of the former conſiſt, theſe are conſtituted of points only, or dots, placed in certain of the little ſquares, formed by the interſection of the lines. Theſe points mark the threads of the warp that are to be raiſed, and the ſpaces left blank denote the threads that are to keep their ſituation: the reſt is managed as in the former.

Design is alſo uſed, in painting, for the firſt idea of a large work, drawn roughly, and in little, with an intention to be executed and finiſhed in large.

Deſign, in painting, is the ſimple contour, or outlines of the figures intended to be repreſented, or the lines that terminate and circumſcribe them: ſuch deſign is ſometimes drawn in crayons, or ink, without any ſhadows at all; ſometimes it is hatched, that is, the ſhadows are expreſſed by ſenſible outlines, uſually drawn acroſs each other with the pen, crayon, or graver. Sometimes, again, the ſhadows are done with the crayon rubbed ſo as that there do not appear any lines: at other times, the grains or ſtrokes of the crayon appear, as not being rubbed: ſometimes the deſign is waſhed, that is, the ſhadows are done with a pencil in Indian ink, or ſome other liquor; and ſometimes

times the design is coloured, that is, colours are laid on much like those intended for the grand work.

The essential requisites of a design are correctness, good taste, elegance, character, diversity, expression, and perspective. Correctness depends on the justness of the proportions, and knowledge of anatomy. Taste is a certain manner of correctness peculiar to one's self, derived either from nature, masters, or studies, or all of them united. Elegance gives a delicacy that not only strikes persons of judgment, but communicates an agreeableness that pleases universally. The character is what is peculiar to each thing, wherein there must be diversity, insomuch that every thing has its peculiar character to distinguish it. The expression is the representation of an object, according to the circumstances it is supposed to be in. Perspective is the representation of the parts of a painting or a figure, according to the situation they are in with regard to the point of sight. The design or draught, is a part of the greatest import and extent in painting. It is acquired chiefly by genius and application, rules being of less avail here than in any other branches of the art, as colouring, *&c.* The principal rules that regard design are, that novices accustom themselves to copy good originals at first sight; not to use squares in drawing, lest they stint and confine their judgment; to design well from life, before they practise perspective; to learn to adjust the size of their figures to the visual angle, and the distance of the eye from the model or object; to mark out all the parts of their design before they begin to shade; to make their contours in great pieces, without taking notice of the little muscles, and other breaks; to make themselves masters of the rules of perspective; to observe the perpendicular, parallel, and distance of every stroke; to compare and oppose the parts that meet and traverse the perpendicular, so as to form a kind of square in the mind, which is the great and almost the only rule of designing justly; to have a regard not only to the model, but to the parts already designed, there being no such thing as designing with strict justness, but by comparing and proportioning every part to the first. All the other rules relate to perspective. See PERSPECTIVE.

DESION, the Macedonian name of the month called by the Athenians anthesterion.

DESISE, a town of France, situated on the river Loire, fifteen miles south-east of Nevers: E. long. 3° 32′, N. lat. 46° 48′.

DESPOTICAL, in general, denotes any thing that is uncontrouled and absolute; but is particularly used for an arbitrary government, where the power of the prince is unlimited, and his will a law to his subjects: such are those of Turky, Persia, and most of the eastern governments; and even those of Europe, if we except the republics, our own, and the Swedish government.

DESPOUILLE′, in heraldry, the whole case, skin, or slough of a beast, with the head, feet, tail, and all appurtenances, so that being filled and stuffed it looks like the entire creature.

DESSAW, a city of upper Saxony, in Germany, situated on the river Elbe, sixty miles north west of Dresden, and subject to the prince of Anhalt Dessaw: E. long. 12° 40′, N. lat. 51° 50′.

DESSERT, or DESART, a service of fruits and sweetmeats, usually served up last to table.

DESSICCATIVE, or DESICCATIVE, in pharmacy, an epithet applied to such topical medicines as dry up the humours flowing to a wound or ulcer.

DESTINIES, in mythology. See PARCÆ.

DESTINY, among philosophers and divines. See FATE.

DESTRUCTION, in general, an alteration of any thing from its natural state to one contrary to nature; whereby it is deemed the same with corruption. See CORRUPTION.

A chemical destruction, or corruption, is nothing but a resolution of the whole naturally mixt body into its parts.

DESUDATION, in medicine, a profuse and inordinate sweat, succeeded by an eruption of pustules, called sudamina, or heat pimples.

DETACHMENT, in military affairs, a certain number of soldiers drawn out from several regiments or companies equally, to be employed as the general thinks proper, whether on an attack, at a siege, or in parties to scower the country.

DETERGENTS, in pharmacy, such medicines as are not only softening and adhesive, but also, by a peculiar activity, conjoined with a suitable configuration of parts, are apt to abrade and carry along with them such particles as they lay hold on in their passage.

DETERIORATION, the impairing or rendering a thing worse: it is just the reverse of melioration. See MELIORATION.

DETERMINATION, in mechanics, signifies much the same with the tendency or direction of a body in motion. See MECHANICS.

DETERMINATION, among school-divines, is an act of divine power, limiting the agency of second causes, in every instance, to what the Deity predestinated concerning them. See PREDESTINATION.

DETERSIVES, in pharmacy. See DETERGENTS.

DETHMOLD, a town of Westphalia, in Germany, fifteen miles north of Paderborn: E. long. 8° 35′, N. lat. 52°.

DETINUE, in law, a writ or action that lies against one who has got goods or other things delivered to him to keep, and afterwards refuses to deliver them.

DETONATION, in chemistry, the noise and explosion which any substance makes upon the application of fire to it. It is also called fulmination. See CHEMISTRY.

DETRANCHE′, in heraldry, a line bendwise, proceeding always from the dexter side, but not from the very angle, diagonally athwart the shield.

DETTINGEN, a village of Germany, about nine miles east of Hanau, in the circle of the upper Rhine: E. long. 8° 45, and N. lat. 50° 8′.

DEVA, a port-town of Spain, situated on the bay of Biscay, forty miles east of Bilboa: W. long. 2° 10′, and N. lat. 43° 20′.

DEVENTER, a city of the united Provinces, and province of Overyssel, about eight miles north of Zutphen: E. long. 6°, and N. lat. 52° 20′.

DEVICE, among painters. See DEVISE.

DEVIL, an evil angel, one of thoſe celeſtial ſpirits caſt down from heaven for pretending to equal himſelf with God. The Ethiopians paint the devil white, to be even with the Europeans who paint him black. There is no mention of the word devil in the Old Teſtament, but only of the word Satan and Belial: nor do we meet with it in any heathen authors, in the ſenſe it is taken among Chriſtians, that is, as a creature revolted from God. Their theology went no farther than to evil genii, or dæmons.

Some of the American idolaters have a notion of two collateral independent beings, one of whom is good, and the other evil; which laſt they imagine has the direction and ſuperintendance of this earth, for which reaſon they chiefly worſhip him: whence thoſe that give us an account of the religion of theſe ſavages give out, with ſome impropriety, that they worſhip the devil. The Chaldeans, in like manner, believed both a good principle and an evil one, which laſt they imagined was an enemy to mankind.

Iſaiah, ſpeaking, according to ſome commentators, of the fall of the devil, calls him Lucifer, from his former elevation and ſtate of glory: but others explain this paſſage of Iſaiah in reference to the king of Babylon, who had been precipitated from his throne and glory. The Arabians call Lucifer, Eblis, which ſome think is only a diminutive or corruption of the word Diabolus.

DEVIL-IN-A-BUSH, in botany. See NIGELLA.

DEVIL'S BIT. See SCABIOSA.

DEVINCTION, in antiquity, a kind of love-charm, deſcribed by Virgil in his eighth eclogue: it conſiſted in tying certain knots, and repeating a formula of words.

DEVISE, or DEVICE, in heraldry, painting, and ſculpture, any emblem uſed to repreſent a certain family, perſon, action, or quality; with a ſuitable motto, applied in a figurative ſenſe. See MOTTO.

DEVISE, in law, the act whereby a perſon bequeaths his lands or tenements to another by his laſt will and teſtament.

DEVISES, a borough town in Wiltſhire, eighteen miles north-weſt of Saliſbury: W. long. 2° 6′, and N. lat. 51° 25′. It ſends two members to parliament.

DEUNX, in Roman antiquity, eleven ounces, or $\frac{11}{12}$ parts of the libra. See LIBRA.

DEVOLUTION, in law, a right acquired by ſucceſſion from one to another.

DEVONSHIRE, a county in the weſt of England, bounded by the Briſtol channel, on the north; by Somerſetſhire and Dorſetſhire, on the eaſt; by the Engliſh channel, on the ſouth; and by Cornwal, on the weſt. From this county the noble family of Cavendiſh take the title of duke.

DEVOTION, a ſincere ardent worſhip of the deity. See PRAYER, ADORATION, WORSHIP, &c.

DEUTERONOMY, a canonical book of the Old Teſtament, and the laſt of the pentateuch of Moſes. See BIBLE.

DEUTEROPOTMI, in Grecian antiquity, a deſignation given to ſuch of the Athenians as had been thought dead, and, after the celebration of the funeral rites, unexpectedly recovered. It was unlawful for the deuteropotmi to enter into the temple of the Eumenides, or to be admitted to the holy rites, till after they were purified, by being let through the lap of a woman's gown, that they might ſeem to be new born.

DEUTEROSIS, the Greek name by which the Jews called their Miſchnah, or ſecond law. See MISCHNAH.

DEUX PONTS, a city of Germany, in the palatinate of the Rhine, ſixty miles north-eaſt of Nancy: E. long. 7° 15′, and N. lat. 49° 25′.

DEW, a denſe moiſt vapour, falling on the earth in form of a miſling rain, while the ſun is below the horizon. See PNEUMATICS.

DEW-BORN, in country affairs, a diſtemper in cattle, being a ſwelling in the body, as much as the ſkin can hold, ſo that ſome beaſts are in danger of burſting. This diſtemper proceeds from the greedineſs of a beaſt to feed, when put into a rank paſture: but commonly when the graſs is full of water. In this caſe the beaſt ſhould be ſtirred up and down, and made to purge well: but the proper cure is bleeding in the tail; then take a grated nutmeg, with an egg, and breaking the top of the ſhell, put out ſo much of the white as you may have room to ſlip the nutmeg into the ſhell; mix them together, and then let ſhell and all be put down the beaſt's throat; that done, walk him up and down, and he will ſoon mend.

DEXTANS, in Roman antiquity, ten ounces, or $\frac{10}{12}$ of their libra. See LIBRA.

DEXTER, in heraldry, an appellation given to whatever belongs to the right ſide of a ſhield, or coat of arms: thus we ſay, bend-dexter, dexter-point, &c. See BEND, POINT, &c.

DEXTROCHERE, or DESTROCHERE, in heraldry, is applied to the right arm painted in a ſhield, ſometimes naked, ſometimes cloathed, or adorned with a bracelet; and ſometimes armed, or holding ſome moveable, or member uſed in the arms.

DEY, in matters of government, the ſovereign prince of Algiers, anſwering to the bay of Tunis. See BEY.

DEYNSE, a town of Flanders, nine miles ſouth weſt of Ghent: E. long. 3° 30′, N. lat. 51°.

DIABETES, in phyſic, an exceſſive diſcharge of urine, which comes away crude, and exceeds the quantity of liquids drank. See MEDICINE.

DIABOLUS. See DEVIL.

DIABOLUS MARINUS. See RAIA.

DIABOLUS METELLORUM, a title given by chemiſts to jupiter or tin, becauſe, when incorporated with other metals, it renders them uncapable of reduction, or at leaſt very difficult to undergo that operation.

DIABROSIS, in medicine. See ANABROSIS.

DIACARYON, in pharmacy. See DIANUCUM.

DIACAUSTIC CURVE, a ſpecies of the cauſtic curves formed by refraction.

DIACHYLON, in pharmacy, an emollient digeſtive plaiſter, compoſed of mucilages or viſcid juices drawn from certain plants.

DIACODIUM, in pharmacy, a ſyrup prepared from poppy heads. It is alſo called the ſyrupus de meconio. As it is of conſequence that all the circumſtances in the directions

directions for compounding this medicine, be exactly followed, we here give the method of preparing it from the London Difpenfatory. Take of the heads of dried white poppies without their feeds, three pounds and a half; of water, fix gallons. Slice the heads, and boil them in the water, often ftirring them that they may not burn, till about a third only of the liquor is left, which will be almoft all imbibed by the poppy heads: then take all from the fire, and prefs the liquor ftrongly out from the heads; in the next place, boil the liquor by itfelf, to about two quarts, and ftrain it while hot, firft through a fieve, and then through a thin flannel: fet it by for a night, that what fæces have paffed the ftrainers, may fubfide; next morning pour off the clear liquor, and boil it with fix pounds of double refined fugar, till the whole comes to the weight of nine pounds, or a little more, that it may become a fyrup of a juft confiftence. This fyrup partakes of all the virtues of the poppy.

DIACOUSTICS, called alfo DIAPHONICS, the confideration of the properties of refracted found, as it paffes through different mediums.

DIADELPHIA, in the Linnæan fyftem of botany. See Vol. I. p. 635.

DIADEM, in antiquity, a head-band, or fillet, worn by kings as a badge of their royalty. It was made of filk, thread, or wool, and tied round the temples and forehead, the ends being tied behind, and let fall on the neck. It was ufually white, and quite plain, though fometimes embroidered with gold, and fet with pearls and precious ftones. In latter times, it came to be twifted round crowns, laurels, &c. and even appears to have been worn on divers parts of the body. See CROWN.

DIADEM, in heraldry, is applied to certain circles, or rims, ferving to inclofe the crowns of fovereign princes, and to bear the globe and crofs, or the flower de luces for their creft. The crowns of fovereigns are bound, fome with a greater, and fome with a lefs number of diadems. The bandage about the heads of moors on fhields is alfo called diadem, in blazoning.

DIÆRESIS, in furgery, an operation ferving to divide and feparate the part when the continuity is a hindrance to the cure.

DIÆRESIS, in medicine, is the confuming of the veffels of an animal body, when from fome corroding caufe certain paffages are made, which naturally ought not to have been; or certain natural paffages are dilated beyond their ordinary dimenfions, fo that the humours which ought to have been contained in the veffels extravafate or run out.

DIÆRESIS, in grammar, the divifion of one fyllable into two, which is ufually noted by two points over a letter, as aulaï inftead of aulæ, diffoliienda for diffolvenda.

DIÆTETÆ, in Grecian antiquity, a kind of judges, of which there were two forts, the cleroti and diallacterii. The former were public arbitrators, chofen by lot to determine all caufes exceeding ten drachms, within their own tribe, and from their fentence an appeal lay to the fuperior courts.

The diallacterii, on the contrary, were private arbitrators from whofe fentence there lay no appeal, and accordingly they always took an oath to adminifter juftice without partiality.

DIAGLYPHICE, the art of cutting or engraving figures on metals, fuch as feals, intaglias, matrices of letters, &c. or coins for medals.

DIAGNOSTIC, in medicine, a term given to thofe figns which indicate the prefent ftate of a difeafe, its nature and caufe.

DIAGONAL, in geometry, a right line drawn acrofs a quadrilateral figure, from one angle to another, by fome called the diameter, and by others the diametral of the figure. See GEOMETRY.

DIAGRAM, in geometry, a fcheme for explaining and demonftrating the properties of any figure, whether triangle, fquare, circle, &c. See GEOMETRY.

DIAGRAM, among ancient muficians. See SCALE.

DIAHEXAPLA, or DIAHEXAPTE, among farriers, a compound medicine, fo called from its containing fix ingredients, *viz.* birthwort and gentian roots, juniper-berries, bay-berries, myrrh, and ivory fhavings. It is commended for colds, confumptions, purfinefs, and many other diforders in horfes.

DIAL. A dial is a plane, upon which lines are defcribed in fuch a manner, that the fhadow of a wire, or of the upper edge of another plane, erected perpendicularly on the former, may fhew the true time of the day.

The edge of the plane by which the time of the day is found, is called the ftile of the dial, which muft be parallel to the earth's axis; and the line on which the faid plane is erected, is called the fubftile.

The angle included between the fubftile and ftile, is called the elevation, or height of the ftile.

Thofe dials whofe planes are parallel to the plane of the horizon, are called horizontal dials; and thofe dials whofe planes are perpendicular to the plane of the horizon, are called vertical, or erect dials.

Thofe erect dials, whofe planes directly front the north or fouth, are called direct north or fouth dials; and all other erect dials are called decliners, becaufe their planes are turned away from the north or fouth.

Thofe dials whofe planes are neither parallel nor perpendicular to the plane of the horizon, are called inclining, or reclining dials, according as their planes make acute or obtufe angles with the horizon; and if their planes are alfo turned afide from facing the fouth or north, they are called declining-inclining, or declining-reclining dials.

The interfection of the plane of the dial, with that of the meridian, paffing through the ftile, is called the meridian of the dial, or the hour-line of XII.

Thofe meridians, whofe planes pafs through the ftile, and make angles of 15, 30, 45, 60, 75, and 90 degrees with the meridian of the place (which marks the hour-line of XII.) are called hour-circles; and their interfections with the plane of the dial are called hour-lines.

In all declining dials, the fubftile makes an angle with

with the hour-line of XII; and this angle is called the diſtance of the ſubſtile from the meridian.

The declining plane's difference of longitude, is the angle formed at the interſection of the ſtile and plane of the dial, by two meridians; one of which paſſes through the hour-line of XII. and the other through the ſubſtile.

This much being premiſed concerning dials in general, we ſhall now proceed to explain the different methods of their conſtruction.

If the whole earth *aPcp*, (Plate LXIX. fig. 1.) were it tranſparent, and hollow, like a ſphere of glaſs, and had its equator divided into 24 equal parts by ſo many meridian ſemicircles, *a*, *b*, *c*, *d*, *e*, *f*, *g*, &c. one of which is the geographical meridian of any given place, as London (which is ſuppoſed to be at the point *a*;) and if the hours of XII were marked at the equator, both upon that meridian and the oppoſite one, and all the reſt of the hours in order on the reſt of the meridians, thoſe meridians would be the hour-circles of London: then, if the ſphere had an opake axis, as *P E p*, terminating in the poles *P* and *p*, the ſhadow of the axis would fall upon every particular meridian and hour, when the ſun came to the plane of the oppoſite meridian, and would conſequently ſhew the time at London, and at all other places on the meridian of London.

If this ſphere was cut through the middle by a ſolid plane *ABCD*, in the rational horizon of London, one half of the axis *E P* would be above the plane, and the other half below it; and if ſtraight lines were drawn from the centre of the plane, to thoſe points where its circumference is cut by the hour-circles of the ſphere, thoſe lines would be the hour-lines of a horizontal dial for London: for the ſhadow of the axis would fall upon each particular hour-line of the dial, when it fell upon the like hour-circle of the ſphere.

If the plane which cuts the ſphere be upright, as *AFCG*, fig. 2. touching the given place (London) at *F*, and directly facing the meridian of London, it will then become the plane of an erect direct ſouth dial: and if right lines be drawn from its center *E*, to thoſe points of its circumference where the hour-circles of the ſphere cut it, theſe will be the hour-lines of a vertical or direct ſouth dial for London, to which the hours are to be ſet as in the figure (contrary to thoſe on a horizontal dial), and the lower half *E p* of the axis will caſt a ſhadow on the hour of the day in this dial, at the ſame time that it would fall upon the like hour-circle of the ſphere, if the dial-plane was not in the way.

If the plane (ſtill facing the meridian) be made to incline, or recline, any given number of degrees, the hour-circles of the ſphere will ſtill cut the edge of the plane in thoſe points to which the hour-lines muſt be drawn ſtraight from the center; and the axis of the ſphere will caſt a ſhadow on theſe lines at the reſpective hours. The like will ſtill hold, if the plane be made to decline by any given number of degrees from the meridian toward the eaſt or weſt: provided the declination be leſs than 90 degrees, or the reclination be leſs than the co-latitude of the place: and the axis of the ſphere will be a gnomon, or ſtile, for the dial. But it cannot be a gnomon, when the declination is quite 90 degrees, nor when the reclination is equal to the co-latitude; becauſe in theſe two caſes, the axis has no elevation above the plane of the dial.

And thus it appears, that the plane of every dial repreſents the plane of ſome great circle upon the earth; and the gnomon the earth's axis, whether it be a ſmall wire, as in the above figures, or the edge of a thin plate, as in the common horizontal dials.

The whole earth, as to its bulk, is but a point, if compared to its diſtance from the ſun: and therefore, if a ſmall ſphere of glaſs be placed upon any part of the earth's ſurface, ſo that its axis be parallel to the axis of the earth, and the ſphere have ſuch lines upon it, and ſuch planes within it, as above deſcribed; it will ſhew the hours of the day as truly as if it were placed at the earth's center, and the ſhell of the earth were as tranſparent as glaſs.

But becauſe it is impoſſible to have a hollow ſphere of glaſs perfectly true, blown round a ſolid plane; or if it was, we could not get at the plane within the glaſs to ſet it in any given poſition; we make uſe of a wire-ſphere to explain the principles of dialing, by joining 24 ſemicircles together at the poles, and putting a thin flat plate of braſs within it.
